XX INTERNATIONAL CONGRESS OF ENTOMOLOGY

Firenze, Italy, August 25-31, 1996

CONGRESS PRESIDENT

B. Baccetti

SECRETARY GENERAL

A. Vigna Taglianti

SECRETARIAT

M. Bologna
A. Zilli

SCIENTIFIC COMMITTEE

E. Tremblay, <i>Chairman</i>	C. Malva
A. Arzone	L. Masutti
F. Bin	A. Minelli
L. Bullini	R. Prota
M. Coluzzi	S. Ruffo
R. Dallai	V. Sbordonì
G. Domenichini	S. Turillazzi
F. Le Moli	G. Viggiani

CONVENORS

A.M. Angioy, <i>I</i>	A. Devonshire, <i>UK</i>	G. Majori, <i>I</i>	G. Scapigliati, <i>I</i>
A. Arzone, <i>I</i>	G. Domenichini, <i>I</i>	C. Malva, <i>I</i>	L.W. Simmons, <i>AUS</i>

M. Covassi, <i>I</i>	A. Levinson, <i>D</i>	J.M.C. Ribeiro, <i>USA</i>	
R. Dallai, <i>I</i>	H. Levinson, <i>D</i>	Y. Robert, <i>F</i>	
V. Delucchi, <i>CH</i>	M. Mackauer, <i>CDN</i>	V. Sbordonì, <i>I</i>	

EDITORIAL NOTES

This book contains the complete texts of the Plenary Lectures and the abstracts of the oral and poster communications presented at the XX International Congress of Entomology.

All the abstracts have not been edited by the Scientific Secretariat and are printed as received.

The abstracts are grouped by sections and are in progressive order. The number of the abstract is composed of two parts: the first two figures indicate the section, the last three figures are the order number. The same reference number is indicated in the programme of the congress.

The reference number of the poster presentations will also appear on the poster board.

CONTENTS

PRESIDENTIAL ADDRESS		
AN OUTLINE OF THE HISTORY OF ITALIAN ENTOMOLOGY		
B. Baccetti	page	XI
OPENING LECTURE		
INSECTS: THE ULTIMATELY BIODIVERSE ANIMALS		
E.O. Wilson	"	XVI
PLENARY LECTURES		
COMPARATIVE SPERMATOLOGY IN INSECT TAXONOMY AND PHYLOGENY		
B. Baccetti	"	XVIII
MOLECULAR POLYMORPHISMS AND RATES OF EVOLUTION		
F.J. Ayala	"	XXV
INSECT EVOLUTIONARY BIOLOGY: LESSONS FROM <i>DROSOPHILA</i>		
J.R. Powell	"	XXIX
LIFE HISTORY EVOLUTION IN INSECTS: THE ROLE OF THE PHENOTYPE IN EVOLUTIONARY THEORY		
S.C. Stearns	"	XXXII
NEUROETHOLOGY OF SEX- AND HOST-ATTRACTION IN MOTHS		
J.G. Hildebrand	"	XXXIV
PROBLEMS AND TRENDS OF AGRICULTURAL ENTOMOLOGY AT THE END OF THE 2ND MILLENNIUM		
M. Wysoki	"	XXXIX
ROLE OF SALIVA IN BLOOD FEEDING BY ARTHROPODS: DIVERSITY AND REDUNDANCY		
J.M.C. Ribeiro	"	XLV
PATTERN FORMATION IN INSECT EMBRYOGENESIS: THE EVOLUTION OF CONCEPTS AND MECHANISMS		
K. Sander	"	XLVIII
INTERNATIONAL COLLABORATION AMONG NATIONAL ENTOMOLOGICAL SOCIETIES		
J.H. Oliver, Jr.	"	LII
CLOSING LECTURE		
ENTOMOLOGY INTO THE THIRD MILLENNIUM		
L.A. Mound	"	LIV

CONTENTS

Section 1. SYSTEMATICS AND PHYLOGENY

1S-1	The Descent of Insects (01-001/01-015)	page	1
1S-2	Biosystematics and Evolutionary Biology (01-016/01-025)	"	5
1G-1	Orthoptera (01-026/01-029)	"	7
1G-2	Stick Insects: Phylogeny, Reproduction and Systematics (01-030/01-036)	"	8
1W-1	Role and Significance of Collections in Systematic Research (01-037/01-039)	"	10
1G-3	Taxonomy of the Dermaptera (01-040/01-054)	"	11
1S-3	Phylogeny and Classification of Caraboidea (01-055/01-071)	"	14
1G-4	Cecidomyiidae and Gallling Insects (01-072/01-091)	"	19
1S-4	Higher-level Phylogeny of Diptera: Morphological and Molecular Evidence (01-092/01-108)	"	24
1G-5	Systematics of the Thysanoptera (01-109/01-115)	"	28
1G-6	Phylogeny of Neuropteroid Insects (01-116/01-123)	"	30
1S-5	Phylogeny of Lepidoptera (01-124/01-132)	"	32
1G-7	Systematics and Biology of Chrysomelidae (01-133/01-154)	"	34
1G-8	Systematics of the Strepsiptera (01-155/01-161)	"	39
1G-9	Curculionidae (01-162/01-172)	"	41
1W-2	<i>Trichogramma</i> Taxonomy (01-173)	"	44
P-01	Posters (01-174/01-272)	"	45

Section 2. BIOGEOGRAPHY AND BIODIVERSITY

2S-1	The Role of Insect Diversity in Agriculture: Ecological, Evolutionary and Practical Considerations (02-001/02-007)	"	70
2S-2	Biodiversity and Biogeography in the Neotropics (02-008/02-020)	"	72
2S-3	Biodiversity and Biogeography of South-East Asia and the Indo-Pacific (02-021/02-031)	"	75
2S-4	Biodiversity and Biogeography in the Austral Regions (02-032/02-042)	"	78
2S-5	Biodiversity of Lepidoptera: Background and Application (02-043/02-053)	"	80
2S-6	The Legacy of Robert C.L. Perkins: 100 Years of Hawaiian Entomology (02-054/02-063)	"	83
2W-1	Effect of the Possible Global Warming on the Insect Diversity and Distribution (02-064/02-071)	"	86
P-02	Posters (02-072/02-146)	"	88

Section 3. MORPHOLOGY AND ULTRASTRUCTURE

3S-1	Spatial Vision: Structures and Mechanisms (03-001/03-009)	"	107
3S-2	Blood-brain Barrier. Current Research and Future Prospects (03-010/03-013)	"	109
3S-3	Egg Structure and Oogenesis (03-014/03-025)	"	110
3S-4	Insect Sensilla: Genesis, Structure and Function (03-026/03-032)	"	113
3S-5	Sperm Structure and Spermiogenesis (03-033/03-039)	"	115
3S-6	Structure and Function of Circulatory Organs (03-040/03-049)	"	117
3S-7	Structure and Function of Insect Midgut (03-050/03-058)	"	119
P-03	Posters (03-059/03-122)	"	122

CONTENTS

Section 4. REPRODUCTION AND DEVELOPMENT

4S-1	Insect Metamorphosis (04-001/04-008)	page	138
4S-2	Sex Determination (04-009/04-014)	"	140
4S-3	Germ Cell and Somatic Cell Interactions in Oogenesis (04-015/04-019)	"	141
4S-4	Maternal Effect Genes and Embryonic Development (04-020/04-025)	"	143
4S-5	Vitellogenesis: Molecular and Biochemical Aspects (04-026/04-030)	"	144
P-04	Posters (04-031/04-062)	"	146

Section 5. CELL BIOLOGY, PHYSIOLOGY AND BIOCHEMISTRY

5S-1	Biochemical and Physiological Interactions between Parasitoids and their Hosts (05-001/05-018)	"	154
5S-2	Transport Mechanisms in Epithelia: Cellular and Molecular Approaches (05-019/05-027)	"	158
5S-3	Water and Osmotic Balance in Terrestrial Insects (05-028/05-034)	"	161
5S-4	The Role of Gut Biochemistry and Physiology in the Action of <i>Bacillus thuringiensis</i> δ -endotoxins (05-035/05-041)	"	162
5S-5	Ecdysteroid Receptor Structure and Function in Insects (05-042/05-051)	"	164
5S-6	Intercellular Junctions (05-052/05-055)	"	167
5W-1	Insect Cell Culture (05-056/05-057)	"	168
5S-7	Sperm Function (05-058/05-065)	"	168
5F-1	Free Communications (05-066/05-077)	"	170
P-05	Posters (05-078/05-168)	"	174

Section 6. INSECT NEUROSCIENCES

6S-1	Evolution of Insect Nervous System (06-001/06-007)	"	197
6S-2	Development of Insect Nervous System (06-008/06-012)	"	199
6S-3	System Neurobiology (06-013/06-018)	"	200
6S-4	Insect Molecular Neurobiology (06-019/06-024)	"	201
6S-5	Advances in Insect Brain: Structure, Function and Genetics (06-025/06-032)	"	203
P-06	Posters (06-033/06-064)	"	206

Section 7. INSECT IMMUNITY

7S-1	Recognition of Non-self (07-001/07-009)	"	214
7S-2	Molecular Defence Mechanisms (07-010/07-029)	"	216
7S-3	Cellular Defence Reactions (07-030/07-042)	"	221
P-07	Posters (07-043/07-055)	"	225

Section 8. GENETICS AND EVOLUTIONARY ENTOMOLOGY

8S-1	Spatial Genetic Structure of Insects and Range Extension (08-001/08-004)	"	229
8S-2	Aphid Populations, Species and Evolution (08-005/08-015)	"	230
8S-3	Insect Morphometrics (08-016/08-023)	"	233
8S-4	<i>Wolbachia</i> Arthropod Relationships: Incompatibility, Parthenogenesis and Transexuality (08-024/08-031)	"	235
8S-5	Hybrid Zones and Speciation (08-032/08-039)	"	237
8S-6	mt-DNA in Insects: Evolutionary Inferences (08-040/08-045)	"	239
8S-7	Insect-Plant Coevolution (08-046/08-050)	"	240
8S-8	Molecular Microphylogenies (08-051/08-054)	"	241
P-08	Posters (08-055/08-142)	"	243

CONTENTS

Section 9. INSECT MOLECULAR BIOLOGY AND GENETIC ENGINEERING

9S-1	Signal Transduction (09-001/09-007)	page	265
9S-2	Transposable Elements and Genetic Transformation (09-008/09-016)	"	267
9S-3	Gene Structures and Expression (09-017/09-024)	"	269
9S-4	Genome Maps and Their Uses (09-025/09-031)	"	271
9W-1	Expression of Genes Encoding Signalling Peptides: Potential for Insect Control (09-032/09-037)	"	273
P-09	Posters (09-038/09-080)	"	275

Section 10. ECOLOGY AND POPULATION DYNAMICS

10S-1	Behavioural Aspects in Population Dynamics (10-001/10-007)	"	286
10S-2	Evolutionary Aspects of Population Dynamics in Insects (10-008/10-019)	"	288
10S-3	Molecular Genetics and Evolution in Transgenic Arthropod Population Dynamics (10-020/10-024)	"	291
10S-4	Sampling and Modelling in Insect Populations (10-025/10-030)	"	292
10S-5	Multitrophic Population Interactions (10-031/10-043)	"	293
10F-1	Free Communications (10-044/10-067)	"	297
P-10	Posters (10-068/10-205)	"	303

Section 11. SPECIAL ENVIRONMENTS ENTOMOLOGY

11S-1	Ecology, Evolution and Systematics of Aquatic and Semiaquatic Bugs (Nepomorpha and Gerromorpha) (11-001/11-021)	"	338
11S-2	Ecology of Marine Insects (11-022/11-032)	"	343
11S-3	Chironomidae: Bionomics, Economic and Medical Significance (11-033/11-045)	"	346
11G-1	Odonata (11-046/11-052)	"	349
11G-2	Hydroadeptophaga (11-053/11-059)	"	351
11G-3	Very Special Environments (11-060/11-062)	"	353
11S-4	Cave Insects and Evolution (11-063/11-069)	"	353
11G-4	Phylogeny and Evolution of Subterranean and Endogean Cholevidae (= Leiodidae Cholevinae) (11-070/11-079)	"	355
P-11	Posters (11-080/11-101)	"	358

Section 12. ETHOLOGY

12S-1	Orthopteran Mating Systems (12-001/12-015)	"	364
12S-2	Sperm Competition in Insects (12-016/12-022)	"	368
12S-3	Dipteran Mating Systems (12-023/12-030)	"	369
12S-4	Signals Used in Mate Attraction and Courtship (12-031/12-038)	"	371
P-12	Posters (12-039/12-098)	"	374

Section 13. SOCIAL INSECTS

13S-1	Caste Development in Social Insects (13-001/13-011)	"	389
13S-2	Kin Selection Theory: Predictions and Tests using Social Insects (13-012/13-023)	"	392
13S-3	Life History Strategies of Social Insects (13-024/13-035)	"	395
13F	Free Communications (13-036/13-070)	"	398

P-17	Posters (17-045/17-068)	"	545

Section 18. URBAN AND STORED PRODUCTS ENTOMOLOGY

18S-1	Biology of Insect Species Associated with Storage and Urban Buildings (18-001/18-012)	"	551
18S-2	Non-chemical Prevention and Control of Urban and Storage Pests (18-013/18-021)	"	554

CONTENTS

18S-3	Success and Failure of Control Measures Utilizing Insecticides and Insectstatics (18-022/18-030)	page 556
18S-4	Fumigation and Modified Atmospheres (18-031/18-036)	" 558
18W-1	Observing, Analyzing, and Modelling Stored-Grain Ecosystems (18-037/18-044)	" 560
18S-5	Physiology of Storage and Urban Insects (18-045/18-068)	" 562
18S-6	Storage and Urban Acarology (18-069/18-078)	" 568
P-18	Posters (18-079/18-132)	" 571

Section 19. ECOLOGY OF PESTICIDES, RESISTANCE AND TOXICOLOGY

19S-1	Insecticide Resistance in Agricultural and Public Health Pests: Origin and Spread (19-001/19-008)	" 585
19S-2	Novel Insecticides (19-009/19-018)	" 587
P-19	Posters (19-019/19-109)	" 590

Section 20. ENTOMOPHAGOUS INSECTS AND BIOLOGICAL CONTROL

20S-1	Artificial Rearing of Insect Parasitoids and Predators (20-001/20-017)	" 613
20S-2	<i>Trichogramma</i> and Other Egg Parasitoids (20-018/20-030)	" 617
20S-3	Critical Issues in Host Selection Behaviour (20-031/20-043)	" 620
20S-4	Functional Morphology of Parasitoids (20-044/20-049)	" 624
20S-5	<i>Orius</i> spp. and Other Hemipterans for Biological Control of Agricultural Pests (20-050/20-058)	" 625
20S-6	Basic and Applied Advances in the Study of Aphelinidae (20-059/20-070)	" 627
20S-7	Biological Control of Stem Borers of Gramineous Crops (20-071/20-081)	" 630
20S-8	Importation and Legislation Issues Affecting Foreign Exploration for Natural Enemies (20-082/20-089)	" 633
P-20	Posters (20-090/20-243)	" 636

Section 21. GENERAL AND APPLIED INSECT PATHOLOGY

21S-1	Current Concepts Relating to Insect Parasitic <i>Rhabditis</i> (21-001/21-015)	" 675
21S-2	Microbial Control of Lymantriids, Thaumetopoeids and Lasiocampids (21-016/21-022)	" 679
21S-3	Recent Advances in Applied Microbial Control (21-023/21-031)	" 680
P-21	Posters (21-032/21-095)	" 683

Section 22. INTEGRATED PEST MANAGEMENT

22S-1	Ecosystem Approaches to Managing Insect Pests of Fruit (22-001/22-008)	" 699
22S-2	Global Plant Genetic Resources for Insect Resistant Crops (22-009/22-020)	" 701
22S-3	Area-Wide Integrated Pest Management (22-021/22-032)	" 704
22S-4	Integrated Pest Management in Olive Groves (22-033/22-042)	" 707
22S-5	Integrated Pest Management Programmes for <i>Citrus</i> (22-043/22-048)	" 709
22W-1	Integrated Pest Management in <i>Citrus</i> (OILB Working Group) (22-049/22-061)	" 711
22S-6	An International Perspective of IPM in <i>Solanum melongena</i> Crop (22-062/22-070)	" 714
22F	Free Communications (22-071/22-111)	" 716
1-2-3-4		
P-22	Posters (22-112/22-151)	" 727

AN OUTLINE OF THE HISTORY OF ITALIAN ENTOMOLOGY

Baccio Baccetti

Istituto di Biologia Generale e Centro CNR
per lo Studio delle Cellule Germinali, Siena, Italy

"Italy was early the home of many famous naturalists and physicians" Howard (1930) wrote in his "A history of applied entomology" "and in entomology has produced many well known workers". At that time such an assertion was easy and practically due.

Entomology, originated in the hands of the Ellenic scientists like Aristoteles (384-322 b.C.), Theophrastus (371-286 b.C.), Dioscorides (1 century a.C.) and the Carthaginiensis Magon, brother of Hannibal (II century a.C.), consisted in a mere reperitory of the generic wasps, ants, locusts, cycads, beetles, flies, mosquitos, louses and cymexes, devoid of any morphological distinction, but it was essentially on the honey bee that some superficial attention was spent. The bee was described without any real observation on the mysterious biology of the insect, except the aristotelic distinction in three castes, tough uncorrectly interpreted. Magon, indeed, added the peculiar theory of the origination of bees from decomposed cadavers.

In the same centuries, in Italy, the Roman Marcus Porcius Cato (234-149 b.C.) wrote "De agricultura", wich included some entomological observations, and the Reatine Marcus Terentius Varro (116-27 b.C.) in his book "Rerum rusticarum", (37 b.C.), was the first latin georgic author to discuss about the honey bees, adding practical suggestions to the aristotelic treatise, mainly obtained from the Italian apicultural experience. Varro therefore prepared the material for the fourth "Georgica" (37-30 b.C.) of Publius Vergilius Maro (70-19 b.C.), conserving the method of Magon for the production of bees from putrified cadavers, and extending studies on the many pests of the bees. The subject was later treated also by Junius Moderatus Columella (I century a.C.), who devoted to apiculture most of the ninth volume of "De re rustica libri XII". In the same century, Caius Plinius Secundus (Plinius Major, 23-24 a.C.-79 a.C.) wrote "Naturalis historia libri XXXVII". With this book the apiculture was reduced to a part of the chapter on small animals ("animales parvi"), which, with "terrestres", "aquatici" and "volucres", formed the four animal classes of his classification. Following Aristotle, Pliny listed in the class "parvi" also few coleopterans, orthopterans, hymenopterans, dipterans, hemipterans without further distinction. The same information were reported by Claudius Aelianus (170-249 a.C.) in his "De vi et natura animalium", while the georgic Rutilius Taurus Palladius (IV century a.C.) synthesized the apiculture of Columella in his "Opus agriculturae".

For nearly the entire millennium to follow nothing new happened in Italian entomology, while the aristotelic Arabs Mesue (?-857), Avicenna (980-1037), Averroes (1126-1194), and the scholastic Europeans Thomas of Cantimpré (1186-1263), Vincent of Beauvais (?-1264), and Albertus Magnus (1193-1280) translated and commented Aristotle. The only Italians were Piero de' Crescenzi (Bologna, 1230-1321) who in his treatise "Il libro dell'agricoltura", published in Florence, 1478, reported the usual aristotelic apiculture and Michelangelo Tanaglia (Florence,

1437-1512) with "De Agricultura" vol. III "Delle Ape" (manuscript). But in the same period entomology extended to the silk moth, the Bombyx. This novelty happened in an anonymus small book, written in Italian around 1473, and presently conserved in the form of manuscript in the National Library of Florence. I have found and published this paper in 1965, under the title "Trattatello di apicoltura, del porre i mori e del porre i bigatti". It is the first book of entomology ever to be written.

In the subsequent century the situation was more or less the same. The Italian Gerolamo Cardano (1501), from Pavia, author of "De subtilitate libri XXI" (1558), Giulio Cesare Scaligero, from Verona (1484-1558), who commented Aristotle (1519), and Piero Andrea Mattioli, from Siena (1500-1577), who commented Dioscorides (1568), mentioned only, supporting their arguments with information taken from the tradition, honey bees, locusts, cicads and few other insects. In addition we must remember the Florentine Giovanni Rucellai (1475-1525) for a short poem in Italian, "Le api" (1568) and two other compositions, both in Latin, both on the silk moth: "Opusculum de Bombyce" (1493) of Ludovico Lazzarelli (1450-1500), and "De Bombycum cura et usum" (1527) of Marco Girolamo Vida (1490-1566). The value of these compositions is rather poor. All the authors were under the complete influence of Vergilius and of Pliny: Vida, e.g., suggested a personal modification to the technology for the production of bees from a putrified cadaver, adapted to the silk moth.

At the beginning of the seventeenth century, the first true Italian entomologist to publish a book on the topic was Ulisse Aldrovandi (1522-1605) from Bologna, doctor in medicine, professor of Bologna University, author of "De animalibus insectis libri septem" (Bologna, 1602) who reports all the aristotelic, plinian and vergilian data, without criticizing them, but adding personal observations gathered in half a century of travels, collections, experimental breeding. At the same time a Neapolitan, Ferrante Imperato (1550-1635), published an enormous volume "Dell'istoria naturale libri XXVIII" where he reported and commented the specimens, including insects, of his museum.

The century was preparing, indeed, the great scientific Galileo's revolution. While the Florentine T. Albmain, in his treatise on the "four elements", explained in 25 lessons, repeated, still in 1668, the aristotelic information, four major scientists abandoned the repetitive classic procedure of the previous centuries and used the galileian experimental method and the galileian instrumentation, under the influence of the "Accademia dei Lincei", that in those very years was to be founded (1603), in Rome. The Tuscan Galileo (1564-1642), elected in 1611, was in fact one of the first fellows of the Academy; he sent a microscope to the academic princeps Federico Cesi (1585-1630) as a gift. This instrument, named by Galileo "occhialino" had been realized by himself and experimented in the examination of a flea, which resulted (as defined in a letter to Cesi, still conserved in the Academy) "orribilissima". In fact, Cesi already knew a

"tubum opticum" given by "duobus germaniis.... artificibus fabrisque" to the Lyncaeus Joannes Faber, an instrument that Faber himself named "microscopium" and experimented on a louse. Galileo, during his stay in Padua, heard about the engine and assembled one "sua sponte, non visu prius tubo similem". The two Germans, in turn, had been stimulated by Joannes Keplerus, who had read the theoretical bases in the volume "De refractione" of Giovan Battista Della Porta (1530?-1615), Neapolitan Lyncaeus. In conclusion: Della Porta had the idea, Keplerus transmitted it to the Germans, the Germans realized the instrument, Faber got it and wrote about the engine, simultaneously Galileo heard the story and contemporarily assembled a similar instrument and sent it to Cesi. The circle of this invention starts and stops in the range of "Accademia dei Lincei".

The four revolutionary entomologists were Francesco Stelluti, Francesco Redi, Pietro Paolo Da Sangallo and Marcello Malpighi. Francesco Stelluti from Fabriano (1577-1653), one of the founders of the "Accademia dei Lincei", had the privilege of working with Galileo's microscope and became the first microscopist in entomology, detecting the minute morphology of the honey bee (published in the ccsian "Apiarium" in 1625) and of Calandra granaria (published in the "Perseo" in 1630). Francesco Redi from Florence (1626-1698), physician at the court of Medici and one of the founders of the Florentine "Accademia del Cimento", experimented on the insect reproduction (1668, 1684) and was the first to exclude the spontaneous generation. This conclusion was substantiated by his Florentine pupil P.P. Da Sangallo (?-1670), who detected the reproduction and metamorphosis of the mosquitoes of Florence (1679). Both Redi and Da Sangallo used the microscope, as a multitude of investigators did in the whole Europe in the second half of the century. But the fourth great entomologist and major microscopist of the seventeenth century was Marcello Malpighi from Bologna (1628-1694), one of the founders of "Accademia del Cimento", who published the famous "Dissertatio epistolica de Bombyce" (London, 1669), where he described the excretory tubules, and in which is included the chapter "De Gallis" in "Anatome Plantarum" (1679), where he found the cecydology. Two other microscopists of this century, even if they were not real entomologists, deserve to be mentioned, and both being important ecclesiastic authorities: the Sicilian G.B. Hodierna (1597-1660), who published a small paper on the anatomy of the eye in the insects ("L'occhio della mosca", Palermo, 1644) and the late aristotelic, but precise morphologist Filippo Buonanni (Rome, 1638-1725) an outspoken enemy of Francesco Redi, who was one of the last epigones of the spontaneous generation. Buonanni in "Observationes circa viventia, quae in rebus non viventibus reperiuntur" (1691), revealed the morphology of many insect mouth apparatuses and described the first Thysanopteron.

Of minor importance, the applied entomologist Paolo Boccone (Frate Silvio), from Palermo (1633-1704).

The eighteenth century opens with a great entomologist, Antonio Vallisnieri (Lucca 1661-1730), professor in Padua, who in an enormous series of treatises and articles (all published from 1700 to 1733), reports important ethological observations on a number of injurious or parasitic insects and proposes a new kind of classification for the class. But in this century, when the great European taxonomists edify the system of insects, and the new continents are explored by travelling entomologists, the Italian supremacy in this science starts to decline. In the early years of this century we have only two marine biologists, Diacinto Cestoni (Livorno, 1637-1718), and Luigi Ferdinando Marsili (Bologna, 1658-1730), who wrote observations on the Kermes coccids. In the rest of the century a number of insect collectors

wrote faunistic descriptions of their countries: Michele Giorna (?-1799), Carlo Allioni (1728-1804) and Leonardo De Prunner in Piedmont, the Trentine G.A. Scopoli (1723-1788) in Carniola (1763) and in Insubria (1786-1788), the Florentine applied naturalist Giuseppc Del Papa (1648-1735) in coastal Tuscany, the Ravennate orthopterologist Giuseppe Zinanni (1692-1753) in Romagna, the Florentine Pietro Rossi (1738-1804), professor of "Insettologia", in the University of Pisa and, therefore, the first chairman of entomology in the world, in "agro florentino et pisano" (1790, 1792-94), the Neapolitan Vincenzo Petagna (1734-1810), in Calabria (1787), Domenico Cirillo (1734-1799) in Naples, and Filippo Cavolini (1756-1810), who studied the insects of the fig, also in Naples. But outstanding biologists of the caliber of the various Redi or Malpighi are no more present in Italian entomology.

In the nineteenth century two new phenomena became evident: the formation of the professional schools, usually around Universities or Museums, and, in the second half of the century, the constitution of the national societies. As far as entomology is concerned, we have already seen that in the eighteenth century, a similar tradition had started in Turin, Florence, Naples. These three important cities continued to produce a number of professional entomologists during the subsequent two centuries.

Turin, in the Institute and Museum of Zoology of the University, generated a famous entomological school, starting from the coleopterist Franco Andrea Bonelli (1784-1830), a former student of Lamarck, and continuing with the applied entomologist and traveller Giuseppe Gené (1800-1847), the museologist traveller Vittore Ghiliani (1812-1878), and the embryologist Filippo De Filippis (1814-1877) (one of the first Italian darwinists), the three famous dipterologists Luigi Bellardi (1818-1889), Ermanno Giglio-Tos (1865-1926) and Mario Bezzi (1868-1927), with the coleopterist Eugenio Sella (1820-1882), the hemipterist amateur Antonio Garbiglietti (1807-1887), the insect anatomist Lorenzo Camerano (1856-1919), the traveller and collector Enrico Festa (1868-1939), the orthopterists Achille Griffini (1870-1932) together with the already mentioned Giglio-Tos, the hymenopterist Giovanni Gribodo (1846-1924), the dermapterist Alfredo Borelli (1858-1943), the lepidopterist Ubaldo Rocci (1885-1943) and the pathologist and parasitologist Edoardo Perroncito (1847-1936). In the present century most of the entomological activity in Turin was carried out by Athos Goidanich (1905-1987), the founder of the Institute of Agricultural Entomology of that University, an eclectic taxonomist and ethologist of many important injurious orders, and by his school. Also the coleopterist Giuseppe Della Beffa (1885-1969) did a rich applied research in the Phytopathology Observatory and wrote a very successful treatise on injurious insects.

In Florence most of the entomological activity was practiced in the famous "Imperial Regio Museo" called "La Specola". The first entomologist there had been the applied coleopterist Carlo Passerini (1793-1857), emerging out of a small group of minor investigators. Finally the Florentine naturalist Bettino Ricasoli (1809-1880) became President of the Government, at the time of Florence capital of Italy, and created the first chair of Zoology in the new born "Istituto di Studi Superiori", covered by the first prestigious Florentine modern entomologist Adolfo Targioni Tozzetti (1823-1902). Targioni was a great scientist and manager. Taxonomist (coccids, aphids, orthopterans), museologist, traveller and applied entomologist. Founder and first president of the "Società Entomologica Italiana" (Florence, 1869), founder and first director of the governmental "Stazione di Entomologia Agraria" (Florence, 1875), the first institution of this kind in Europe. Targioni had a large school of students and associates:

the lepidopterist Pietro Stefanelli (1835-1919), the coleopterists Vittorio Pecchioli (1790-1870), Pietro Bargagli (1844-1918), and Angelo Senna (1866-1952), the collectors Guelfo Cavanna (1850-1920) and Ferdinando Piccioli (1821-1900), the muscologist coleopterist Antonio Carruccio (1839-1923), the aphidologist Gustavo Del Guercio (1863-1954), and, above all, the encyclopedic genius Antonio Berlese (1863-1927), who was to be his successor in directing the "Stazione". In this group must be mentioned also the orthopterist and muscologist Apelle Dei from Siena (1819-1903), the zoologist Eugenio Ficalbi (1858-1922), professor in Pisa, where he published excellent papers on mosquitoes, and the insect anatomist Pio Mingazzini (1864-1905), professor of Zoology in Florence. Berlese, born in Padua, was an excellent anatomist and a histologist of insects, a modern applied entomologist, who discovered new formulations of insecticides and efficiently practiced the biological control, a major acarologist and author of a monumental treatise of entomology. Founder of the entomology journal "Redia" (1903) he had a large school of students and associates, including some amateurs: the great entomologist Filippo Silvestri (1873-1949), his former assistant in the Entomology Laboratory of Portici, the amateur coleopterist Giuseppe Leoni (1866-1928), the forest entomologist Giacomo Cecconi (1866-1941), the orthopterist Guido Paoli (1881-1947), the lepidopterist Roger Verity (1883-1959), the applied entomologists Ettore Malenotti (1887-1949), Costantino Ribaga (1870-1945), Leopoldo Chinaglia (1890-1916) and Antonio Melis (1891-1963), who was also an appreciated thysanopterist and became the successor of Berlese in the direction of the "Stazione di Entomologia Agraria". He also founded in 1950 the "Accademia Nazionale Italiana di Entomologia", together with Goidanich, Grandi and Grandori. Successor to Melis in the Direction of "Stazione" was Rodolfo Zocchi (1922-), forest entomologist.

The school of Naples was not of minor importance. In nineteenth century entomology flourished under the dynasty Costa: Oronzio Gabriele Costa (1787-1867) and his son Achille Costa (1823-1898) wrote on various entomological topics and published other studies on insects injurious to the olive tree. The Costas wrote together a splendid "Fauna del Regno di Napoli" and Achille, alone, an enormous "Geofauna Sarda". Another son of Oronzio, Giuseppe Costa, worked in Lecce on the fauna of Terra d'Otranto (1871). In the years 1890-1903, the already mentioned Antonio Berlese, inaugurated the chair of Entomology of the University of Portici and had, as his first important pupil, Filippo Silvestri who succeeded to him when the master left Naples for Florence. Silvestri was an outstanding scientist. A taxonomist and morphologist in a large number of orders, discovered and described an enormous amount of insects and myriapod species, genera, families, orders, all new for science. He was one of the major experts in the biological control by parasitoids in the world, he created the modern style for the monographical study of the single injurious species (taxonomy, morphology of all stages, ethology, control, list of parasitoids with their morphology and reproductive biology). He was also a great traveller and initiated an important journal, at present named "Bollettino del Laboratorio di Entomologia Agraria" of Portici, and a splendid treatise of applied entomology. He was also a major Master: his school still includes many of the most active Italian agricultural entomologists. Among his former students and associates we must remember the coccidologists Gustavo Leonardi (1869-1918) and Vincenzo Lupo (1908-), who started a nice school in Catania, the chalcidologist Luigi Masi (1879-1961), the applied entomologists Giovanni Martelli (1877-1954) and Giuseppe Russo (1897-1971), the orthopterist Giuseppe

Jannone (1907-1971), the aphidologist Domenico Roberti (1912-), who had a valid school in Bari, and many others. But also the Institute and Museum of Zoology of the University of Naples continued to have good entomologists. Ernesto Caroli (1878-1958) studied Collembola, Umberto Pierantoni (1876-1959) was a learned specialist of the endosymbiosis in insects and Director of the Institute; after him the orthopterists Mario Salfi (1900-1970), who succeeded him on the chair and Marcello La Greca who started a sound school in the Institute of Zoology of Catania. The last one was a well recognized expert in insect biogeography and morphology, and gave the first description of the resilin. Another member of the same Neapolitan school has been the endocrinologist Baldassarre De Lerma (1908-1996) who discovered the corpora cardiaca. But in addition to Turin, Florence and Naples, which for several reasons had maintained for a long time the leadership in entomology, other schools became very active in the last two centuries.

In the nineteenth century the pathologist of the silk worm Carlo Agostino Bassi (1773-1856) worked in Milan, while the amateur coleopterist Antonio Villa (1806-1895) and his brother Giovanni associated with the group of Florence in the foundation of the "Società Entomologica Italiana". Felice Franceschini (1854-1928), school professor of applied entomology in Milan, published in 1891 a book on "Insetti Nocivi" and many papers of the silk moth. Eugenio Bettoni (1845-1898) wrote a book on the fauna of Brescia. Paolo Magretti (1854-1913) was a good traveller hymenopterist amateur, and Emilio Turati (1858-1938) a famous lepidopterist. More recently the coleopterist and biogeographer Mario Magistretti (1902-1974) was one of the more relevant investigators in modern taxonomy.

In the same time an important school, essentially specialized in the study of the silk moth, arose: the already mentioned C.A. Bassi, Emilio Cornalia (1824-1882) and Remo Grandori (1885-1955), a pupil of Battista Grassi (see below), were authors of important handbooks on the Bombyx. Grandori, with his wife Luigia, created an important school, whose major exponent is now the chalcidologist Giorgio Domenichini, professor in Piacenza. Connected to the Museum of Natural History of Milan Lucio Micheli (1887-1951) studied the biology of Apidae. Later Cesare Conci (1920-) covered the position of Director of the Museum and that of President of the "Società Entomologica Italiana" being an expert in Anoplura, Odonata and Psylloidea.

In Bergamo Antonio Curò (1828-1906), lepidopterist, published an appreciated catalogue on Italian Lepidoptera.

In Pavia, where Scopoli had been very active in the eighteenth century, the professor of the Agriculture in the University Giuseppe Bayle-Barelle (1768-1811) published an useful book on injurious insects (1809) and also the professor of Zoology Giuseppe Balsamo-Crivelli (1800-1874) worked in applied entomology while the school professor Angelo De Carlini (?-1811) wrote on Orthoptera and Hemiptera. More recently a member of the Roman school of Battista Grassi (see below), Carlo Jucci (1897-1962) founded the first Italian school of genetics, and became a learned investigator of the biology of Termites and generally in insect physiology. Some students of his school became well reputed geneticists, as did Adriano Buzzati-Traverso (1913-1983), Renzo Scossiroli and Riccardo Milani, all working on *Drosophila*. One further member of the Pavia group, Mario Pavan (1918-), became a well known expert in insect speleology, physiology and ecology.

Also Parma had good entomologists. First of all the dipterologist Camillo Rondani (1808-1879), investigator of the biological equilibrium by original experiments of natural control. Subsequently Giovanni Passerini (1816-1893), professor in the

University of Parma, made important studies on the Aphididae. In this line we must put also the great coleopterist Antonio Porta (1874-1971) author of "Fauna Coleopterorum Italica", in 8 volumes, a free lecturer in Parma University.

In Modena the isolated collector Luigi Picaglia (1816-1893), published on the insects of the territory.

A peculiar centre for entomological studies has been Genoa, where already Massimiliano Spinola (1780-1857), hymenopterist, published "Insectorum Liguria species novae aut rariores" (1806-1808). Subsequently Giacomo Doria (1840-1913), a great traveller and naturalist founded in Genoa a "Museo Civico di Storia Naturale" (1867) as the location for the study of all the material that the numerous expeditions had collected in tropical countries around the world. He was a learned entomologist and the first director of the Museum. At that time the professor of Zoology of the University, Corrado Parona (1848-1922) published on Apiculture and on Apterygote insects. In the Museum, after Doria, the famous coleopterist Raffaele Gestro (1845-1936) became director and created a good team of entomology curators, including the traveller Leonardo Fea (1852-1903), the hymenopterist Giacomo Mantero (1878-1949), Luigi Masi chalcidologist who came from Naples, the coleopterist Edoardo Gridelli (1895-1958) from Trieste, the coleopterist and orthopterist Felice Capra (1896-1991), the coleopterist and hymenopterist Armando Baliani (1874-1895), the hymenopterist Delfa Guiglia (1902-1983). Other important fellows of this group were the amateurs Agostino Doderò (1864-1937), coleopterist, Cesare Mancini (1881-1967), hemipterist, Emilio Berio (1905-1993), lepidopterist, and Giovanni Binaghi (1907-1975), coleopterist, as well as Ferdinando Solari (1877-1956), curculionidologist, and Fabio Invrea (1884-1968), specialist in Mutillidae, who both were in turn presidents of the "Società Entomologica Italiana", after having transferred it from Florence to Genoa in 1922.

Like Genoa, also Trieste had a good tradition of entomology in the "Museo Civico di Storia Naturale" of Trieste and in the Museum "Pietro Rossi" of Duino. A line of important coleopterists worked in the two institutions: Arturo Schatzmayr (1880-1950), Giuseppe Muller (1880-1964), Carlo Lona (1885-1971), Edoardo Gridelli (1895-1958) and the myrmecologist Bruno Finzi (1897-1941). Also Fiume had a good entomologist, Guido Depoli (1879-1948) who studied the coleopterans of Liburnia.

In Venice Nicolò Contarini published a catalogue of insects of the area of Venice and Padua (1843) and Alessandro Ninni (1837-1892) did further orthopterological contributions in the same area.

In Vicenza the abbot Francesco Disconzi published in 1865 "Entomologia Vicentina".

A particular attention must be paid to Verona, where already in the eighteenth century Zaccaria Betti (1732-1788) published a poem on the silk worm, two other books on the same type of moth and on the worms of the apple tree. Orseolo Massalongo (1854-1901) published a "Prospetto ragionato degli insetti della provincia di Verona" (1891). Subsequently Edoardo De Betta (1822-1896) published observations on locusts and bees, Adriano Garbini (1857-1940) worked in hydrobiology and apiculture, and Alberto Brasavola-Di Massa (1886-1956) studied the coleopterans of Trento. But it is in the present century that entomology in Verona, at the "Museo Civico di Storia Naturale", reached a world wide reputation under the leadership of Sandro Ruffo (1915-), a famous coleopterist and biogeographer and chief of an appreciated entomological school.

Also Trento had some good entomologists: the Canestrini family, with Giovanni Canestrini (1835-1900), professor in Padua, an appreciated acarologist who wrote also a good treatise

on apiculture, Pietro Buffa (1871-1941), thysanopterologist who worked some years in Padua and in Florence, the Cobelli brothers, Giovanni (1849-1937), director of "Museo Civico" of Rovereto and Ruggero (1838-1921), who wrote on homoptera, orthoptera and hymenoptera of the region, the applied entomologist Agostino Lunardon (1857-1933), and the great investigator of Bombyx Luciano Pigorini (1882-1967).

After the major entomologists of the seventeenth century Aldrovandi and Malpighi, Bologna continued the tradition in the last two centuries with the applied entomologist Giuseppe Bertolani (1804-1878), the coleopterist Andrea Fiori (1854-1933), Carlo Ermery (1848-1925), professor of Zoology, one of the best myrmecologists of any time. After him, his former student Guido Grandi (1886-1970), who spent many years in Portici assisting Filippo Silvestri, covered the first chair of entomology in Bologna University, and founded a famous Institute and an appreciated journal ("Bollettino dell'Istituto di Entomologia dell'Università di Bologna"), and was one of the founders as well as the first president of the "Accademia Nazionale Italiana di Entomologia". Grandi was a great scientist. He studied comparative morphology and ethology in a number of injurious insects, created a new approach to agricultural entomology studying the various biocenoses, was a major taxonomist of Agaonidae, investigated the ethology of Hymenoptera, studied and defended the biologic equilibrium, discouraging the use of insecticides, wrote the fundamental treatise "Introduzione allo studio dell'entomologia". He had a superb circle of students, assistants and associates who obtained prestigious academical positions: first of them the professor of Zoocultures Anita Vecchi (1893-1953), a learned investigator on Apis and Bombyx. Subsequently the already mentioned Athos Goidanich who founded the Entomology Institute of Turin, the hemipterist Antonio Servadei (1908-1979), who had previously started a valid school in Sassari, and later in Padua, the dipterist Filippo Venturi (1910-1975) founder of a good school in Pisa, the ethologist Leo Pardi (1915-1990), who started the Italian comportamental ecology and had valid students and associates in Florence, the aphidologist Minos Martelli, who succeeded to Grandori in Milan, the already mentioned coleopterist Sandro Ruffo, who started the school of Verona, the neuropterist Maria Matilde Principi who succeeded to Grandi's chair, the coleopterist Giorgio Fiori (1923-1983), the tachinologist Egidio Mellini, the forest entomologist Rodolfo Zocchi, who directed, following Melis, the "Stazione di Entomologia Agraria" in Florence, and many others including the lepidopterist amateur Attilio Fiori (1883-1958), the myrmecologist Carlo Menozzi (1892-1943) and the ephemeropterist Marta Grandi (1915-). The already mentioned Giorgio Fiori started good schools in Sardinia first and later in Perugia, where the trichopterologist Giampaolo Moretti and his school in the Zoology Institute were also working.

In Palermo there was the already mentioned Paolo Boccone, who published some entomological observations and studied apiculture. This city too, had good entomologists in the eighteenth century: the agricultural entomologists Francesco Minà-Palumbo (1814-1899) and Teodosio De Stefani-Perez (1853-1935), the taxonomists Giuseppe Riggio (1848-1914), Enrico Ragusa (1849-1924), Luigi Failla Tedaldi (1853-1930), the cytologist and embryologist Andrea Giardina (1875-1948), professor of zoology, the lepidopterist and medical entomologist Mario Mariani (1898-1965), and has now an active University Institute of Agricultural Entomology.

A peculiar situation, which was left last in this overview, is the one regarding the Roman Entomology. As we have seen the imperial Rome had the pride to host several of the Latin encyclo-

pedic entomologists. Unfortunately very few scientific works were carried out here until the end of the nineteenth century, except for a few isolate works, as far the already mentioned microscopists Francesco Stelluti and Filippo Buonanni, or the applied orthopterists Luigi Doria, who published in 1816, and Luigi Metaxà (1778-1842), who published in 1825, or Carlo Luciano Bonaparte (1803-1857), who did some researches on lepidoptera. In the second half of the nineteenth century Giovanni Battista Grassi (1854-1925), covered the chair of Comparative Anatomy at the University and started a series of outstanding entomological researches. Initially he studied the taxonomy and embriology of the honey bee, but later he switched on to the comparative morphology of Myriapoda and Thysanura ("I progenitori degli Insetti"), and to the sociality of Isoptera ("Costituzione e sviluppo della società dei Termitidi"), of the Embioptera, and their intestinal symbionts. In 1896 the pathologist of Rome University Amico Bignami (1862-1929) suspected that the malaria was inoculated by mosquitoes. Immediately Grassi devoted himself to the malaria problem revealing, in 1898, the importance of Anopheles (while Roth, in the same year spoke about "some mosquitoes") in the transmission of the disease, following in the cells of the body of the insect the development of Plasmodium ("Studi di uno zoologo sulla malaria", 1900). After a study on Phlebotominae, he discovered the complex cycle of Phylloxera, and published the book "Contributo alla conoscenza delle Fillosserine ed in particolare della Fillossera della vite" (1912). It is clear that this variety of investigations could have been enough to assure the glory to four or five scientists. The phenomenon of Grassi is destined to remain unrivalled. Obviously he had a lot of students too: among the entomologists we find the already mentioned Silvestri, Anna Foà (1876-1944) who covered the chair of sericulture in Portici, the already mentioned Carlo Jucci, founder of Italian entomological genetics in Pavia, and Remo Grandori, the

founder of the modern school of entomology in Milan. For these years, around the professor of Zoology Antonio Carruccio, a modest museologist, former pupil of Adolfo Targioni Tozzetti, we find in Rome only passionate and learned amateurs: a line of coleopterists, Paolo Luigioni (1873-1937), author of "I coleotteri d'Italia", Pio Mingazzini, Adelchi Tirelli, G.E. and F. Rasetti, Marcello Cerruti (1818-1870), a line of lepidopterists, Fortunato Rostagno (1853-1934), Lillo Barbera, Sergio Beer, Orazio Querci, Enzo Romei, Federico Hartig, a good line of travellers and tropical collectors, as Vito Zanon (1875-1949), as the great speleologist and traveller, Saverio Patrizi-Montoro (1902-1957) and the more famous traveller, Edoardo Zavattari (1883-1972) who in turn directed the Institute of Zoology. Moreover we have the dipterist Giuseppe Tuccimei (1851-1915), the hymenopterist Giuseppe Lepri (1870-1952), and a line of parasitologists, as Giulio Alessandrini (1866-1954) and Giuseppe Saccà. Grassi's had been for all of them an outstanding personality. After his death, entomology in Rome was neglected, and almost half a century passed before the signs of a renaissance could be seen. This happened thank to the work of an obscure primary school teacher, Omero Castellani (1903-1974), a modest, but passionate collector, who directed a lot of children to work with himself. He founded in 1945 the ARDE (Associazione Romana di Entomologia), publishing a small Bulletin. The children grew up and became the well reputed professors of Entomology and of Zoology in several Universities of Rome and neighbouring cities.

Italian entomology is a strong tree. This congress has the honour to host representatives of the many branches of the schools related to Targioni, Costa, Emery, Berlese, Silvestri, Grandi, Jucci, Goidanich, Ruffo, La Greca and the other protagonists of this history. I hope you will look on them, and unveil through in their personalities the traces of their long ancestry.

INSECTS: THE ULTIMATELY BIODIVERSE ANIMALS

Edward O. Wilson

Museum of Comparative Zoology,
Harvard University, Cambridge, USA

Viewed as part of the great evolutionary tableau of life, the most distinctive features of insects is their dominance on the land, which has persisted in stark contrast for 360 million years with their virtual absence in the sea. They are the most numerous animals of intermediate size, that is, 0.1 mm - 100 mm in length, and possess the greatest total biomass of any terrestrial class or phylum of animals. Insects are also hyperdiverse (Wilson, 1992). They fit one of the rules of biodiversity: within each monophyletic assemblage of species (such as a family) it is typically the case that one of the constituent taxa (a genus in the family) is far more diverse (in this case comprises more species) than can be expected by chance alone (Dial and Marzluff, 1989). The assemblage, in other words, is off the curve, significantly higher in representation than would be expected if it belonged to an ordinary, randomly generated frequency distribution. The most hyperdiverse taxa, in descending taxonomic rank from kingdom downward are: Arthropoda within the Animal Kingdom, Hexapoda (insects) within the Arthropoda, Coleoptera (Beetles) within the Hexapoda, Chrysomelidae (leaf beetles) and Curculionidae (weevils) within the Coleoptera.

How many species of insects are there? Between 750,000 and 1 million nomenclaturally valid species have been described; the exact number is not known because no catalog of the entire world fauna exists at this time. Also, the percentage of synonyms, possibly as high as 10 percent, is unknown. An intermediate number in this range, say 800,000, composes very roughly three-quarters of all animal species and half of all species of all kinds of organisms.

The *true* number of insect species, described plus undescribed, can only be guessed to the nearest order of magnitude. Extrapolating upward from the number of beetle species in the canopy of a single tiliaceous tree in Panama, Terry Erwin (1982, 1983) famously estimated 30 million insect species worldwide. Although his pioneering effort spurred worldwide interest in the great magnitude of insect diversity, there were potential large errors in each step of the extrapolation-including variation in arboreal residents from one tree species to the next, the percentage specialized on each tree species, localness of the specialized species, and others-to move the permissible estimate up or down several fold. Estimates by other authors based on extrapolation upward from entire well-censused faunas, including the Hemiptera of part of Sulawesi and the insects of great Britain,

place the number of insect species worldwide at 2-6 million (review by May, 1992). Even this more modest diversity, if correct, far outweighs that likely to exist in all the rest of the Animal Kingdom.

Why are there so many insect species? We have only hypotheses, and even taken together they still might not identify all the parameters. One key factor is surely preemptive antiquity: the insects were able to saturate terrestrial and freshwater habitats very early in geological history of life on the land. Apterygotes appeared by the middle Devonian, where they coexisted with centipedes, millipedes, spiders, and trigonotarbids, and winged insects by the end of the Lower Carboniferous (Gray and Shear, 1992). During the Upper Carboniferous and Permian, there followed a massive adaptive radiation, peaking at 30 orders, close to the number today. The number of families rose more or less steadily throughout this history, with a dramatic jump during the Cenozoic in concert with the expansion of the flowering plants (Carpenter, 1992; Jarzembowski and Ross, 1993).

The evidence suggests that the preemption entailed early and multifarious adaptations to terrestrial vascular vegetation, from its earliest origins to the present day. Many of the most diagnostic characters of insects, including the details of metamorphosis, feeding devices and physiology, nest-building, and oviposition behavior, reflect fine-tuned exploitation of plants, as well as (especially for saprophages and carnivores) life in the soil.

The quantum advances in the evolutionary history of insects were first their origin as a fully terrestrial group; second, the invention of adult winged flight, the first such achievement in the history of life; third, the folding of wings, allowing penetration of winged adults into small spaces; fourth, the origin of advanced hemimetabolous and then holometabolous metamorphosis, which in conjunction with flight allowed exploitation by individual species of a wider range of niches; and finally, the origin of the social insects, whose superbly integrated colonies came to dominate much of the land environment during the Cenozoic era.

Insect diversity is one of the most important but least understood phenomena in science today. It has profound implications for our understanding of evolution and ecology. Furthermore, given the ubiquity and power of insect life all around us, its careful study is necessary for the planning of a healthy, sustainable human environment.

COMPARATIVE SPERMATOLOGY IN INSECT TAXONOMY AND PHYLOGENY

Baccio Baccetti

Istituto di Biologia Generale e Centro CNR
per lo Studio delle Cellule Germinali, Siena, Italy

In a previous paper¹ I have reviewed the fantastic differentiation and evolution of sperm structure and function in the Insecta, and I have observed that the various organelles typical of insect groups tend to persist in advanced levels of evolution and differentiation. This is in agreement with the principle of perseverance in evolution proposed by Baccetti².

I will now present a general picture of insect sperm features, ordering the various findings into a phylogenetic tree (Fig. 1). Phylogenetical insect spermatology was attempted by Retzius³ and Franzen⁴ at the light microscopy level, by me in several subsequent papers^{1,5-8} and by Dallai⁹ based upon electron microscopy. Jamieson¹⁰ recently produced a comprehensive treatise on the subject. In this paper I reduce to a minimum the references: the full literature is presented in the papers 2-10, and particularly in 1.

As observed by Baccetti¹, the sperm model closest to that of the presumed Arthropod ancestor is retained (Fig. 1) by the encysted Collembola sperm and by the free sperm of iapiigid Diplura (acrosomal complex endowed with perforatorium, 9+2 axoneme, conventional mitochondria). In campodeid diplurans the typical insect axoneme pattern, 9+9+2, appears. Here the accessory microtubules group in one bundle and retain the primitive number of 13 protofilaments in the cross section of their wall. From this model the Archeognatha sperm seems to derive; they show, in fact, accessory tubules grouped in two rows and containing 16 protofilaments in cross section of their wall. The Zygentoma model is more advanced, and closer to that of most Pterygota, having the 9+9+2 axonemal pattern with accessory tubules comprised of 16 protofilaments, each positioned near one doublet. But a parallel, independent line, that of Protura, seems to have started from the Insect ancestor. Here we see two evolutionary steps. The first step belongs to genera with encysted sperm, which are motile only when extremely close to the egg in the female genital apparatus, the second belongs to definitely immotile genera. None of them exhibit evolution toward the classical insect sperm characters. In the encysted, elongate model (*Acerentomon*, *Acerentulus*, *Eosentomon* a.o.) the acrosomal complex lacks a perforatorium, mitochondria are still conventional, and the axoneme is comprised of doublets endowed with only the inner dynein arm and arranged according the 12+0, 14+0 or 16+0 pattern. In the immotile model the regression is still more evident: the sperm is globular or discoidal, devoid of acrosomal complex, centriole, axoneme, and comprised of only a nucleus and a few conventional mitochondria.

In this long path of step by step regression, Protura recall more strictly Pycnogonida or Arachnida than Insecta.

The sperm model of Zygentoma leads into Pterygote insect phylogeny. All groups seem to be clearly characterized by hyper-telic sperm, and by the 9+9+2 axonemal pattern with 16 protofilaments forming the accessory microtubule wall. The only exception are Ephemeroptera (the oldest Pterygota), where the classic

insect sperm is still lacking, the acrosomal complex is monolayered (perforatorium absent), the axoneme is 9+9+0, doublets have only the inner arm and accessory microtubules have the primitive number of 13 protofilaments in their wall. Moreover, the single mitochondrial derivative has conventional cristae, no crystallomitin, and is flanked by two crystalline rods which play the role of accessory bodies. The highly evolved ephemeropteran family Leptophlebiidae has coccoidal sperm containing a perforatorium in the center of the acrosome, and one conventional mitochondrion or no mitochondria at all, according to the species. Centriole and axoneme are absent. The first are primitive characters, aflagellarity is a quite specialized one. This complex picture indicates Ephemeroptera as a very peculiar and independent branch among pterygote insects, conserving some plesiomorphic characters lost elsewhere but still evolved toward immotility. The first, real pterygote sperm is present in Odonata. They have a bilayered acrosome, a 9+9+2 classic axoneme with 16 protofilaments in the wall of accessory tubules, two partially crystallized mitochondrial derivatives (crystallomitin protein synthesis starts at this level) and two compact accessory bodies flanking the axoneme. No involved or aflagellate forms are present in this order, which exhibits the most classic insect sperm model. From several points of view Ephemeroptera and Odonata seem to be absolutely independent orders, and the group Palaeoptera appears to be a quite artificial taxon (Fig. 1).

All other orders belong to the Neoptera branch, and can be grouped in the three classic divisions of Polyneoptera, Paraneoptera and Oligoneoptera (holometabolic insects) (Fig. 1).

As sperm structure is concerned, all the orders of Polyneoptera (Fig. 2) except Isoptera and Phasmida appear quite similar, retaining almost all the characteristics of the pterygote sperm model. Isoptera and Phasmida, in fact, show very peculiar sperm characters that suggest a long and quite independent evolution.

In the more traditional stock the most conservative sperm model is that of Blattodea having a long sperm (some hundreds μm), with an acrosome endowed with a perforatorium, a 9+9+2 axoneme, having 16 protofilaments in the accessory tubules, flanked by two long, partially crystallized mitochondrial derivatives and more or less long dense processes arising from the centriolar adjunct. From the adjunct delicate links (connecting bands) also arise joining the mitochondrial derivatives to the axoneme for almost their entire length. One long, flat, membranous cistern is present close to the adaxonemal surface of each derivative. Mantodea maintain all of the blattoid characters, but have a quite short perforatorium, and the system of links between mitochondrial derivatives and axoneme is much richer, including two dense lateral and one or two additional delicate central bands. From this ancestral dictyopteran stock five main phylogenetic lines seem to have radiated. The Grylloblattodea line is peculiar. It retains all the characters of Blattodea, but has

only a monolayered acrosome, and therefore appears more evolutionarily derived. A second line includes Dermaptera, Embioptera and Plecoptera. They retain blattoid axonemal and periaxonemal structures and the partially crystallized mitochondrial derivatives, but while Dermaptera have a 3-layered acrosomal complex (plesiomorphic) the other two orders have a monolayered one, because only the acrosome is present, and therefore they seem to be more derived. All the three orders have more or less long processes arising from the centriolar adjunct. However, while Dermaptera have a single double triangular process close to the axoneme, Plecoptera have a long uneven, lateral rodlet flanking the axoneme and Embioptera have three rodlets: a bilateral pair of long rodlets, and one shorter rodlet.

The three other lines each end with one of the three classic orthopteran superfamilies Tettigonoidea, Grylloidea (suborder Ensifera) and the suborder Caelifera (Fig. 2). An evident preliminary step in the line to Tettigonoidea is the strange Australian group of Coloolidea which exhibits all the characters of the dictyopteran stock, including the three connecting bands, but has a flat nucleus in a flat head. The last in Tettigonoidea becomes arrow-like because of the peculiar shape of the acrosomal complex and because an accessory extra-axonemal longitudinal microtubule appears between each of the lateral connecting bands and the axoneme. Accessory bodies are absent. On the line going to Grylloidea, Gryllacridoidea are inserted. This group retains all the blattoid characters, and in addition acquires two accessory bodies that in some species are very small, no larger than a microtubule, while in others are bigger, and crescent shaped. Grylloidea exhibit the same characters, but in the place of accessory normal microtubules or bodies have two 10 nm thin tubules, and in most families a long segment of the terminal part of the axoneme is stiffened and immotile due to tanning of doublet and singlet microtubules. While the examined orthopteran superfamilies (all ensiferans) have in common only basic features of dictyopteran stock, Caelifera show some important, new characteristics which render the group homogeneous. The most evident is that the sperm tends to be extremely thin, elongate-cylindrical and as a consequence the extra-axonemal cytoskeleton increases, as well as the two mitochondrial derivatives that are almost completely filled with crystallomitin, and have the transversally oriented cristae restricted to a reduced, thin cortex. Moreover, a pair of thin, extra-axonemal 10 nm thin tubules flanks the axoneme laterally in almost all the superfamilies. Furthermore, the acrosome is always inserted on the nucleus by two lateral processes that flank the nucleus itself on two sides. The various superfamilies progressively show further characters. Cyndrachetidae have a rather primitive sperm that is still similar to the dictyopteran sperm (obviously with the addition of the three general caeliferan characters listed above). It has, in fact, a three-layered acrosome and 9+9+2 axoneme, but has 3 connecting bands, the two lateral containing one extra-axonemal 10 nm thin microtubule. From this model, assumed as ancestral for all caeliferans, one or two lines arise. The first one includes Tetrigoidea and Tridactyloidea, which are very similar each to the other, exhibiting all the cyndrachetan characters. In addition, the two mitochondrial derivatives differ in size and generally the number of connecting bands is greater than two. In Tetrigoidea there are 2-4 of these bands, and the two extra-axonemal tubules reach the dimensions of normal microtubules; in Tridactyloidea there are five bands, and in the place of the extra-axonemal microtubules two dense, accessory bodies are present. They recall the two crystalline accessory bodies typical of Phasmoidea, and, like them, are derived from the activity of the Golgi complex.

The second line includes the Eumastacoidea and the Acridomorpha. All the cyndrachetoid characters are conserved; the two mitochondrial derivatives are equal in size and shape. An important new character is that the entire plasma membrane (except in the very tip of the acrosomal region) is covered by a thick glycocalyx forming a fuzzy coat of 10 nm or more-long microfilaments arranged perpendicular to the surface. Eumastacoidea have three evident granular connecting bands. The two lateral bands contain an extra-axonemal 70 nm microtubule. In this group the microfilaments of the fuzzy coat are 10 nm long. Acridomorpha have two thin connecting bands between derivatives and axoneme. The bands contain a thin, 10 nm microtubule. The centriolar adjunct is semicircular in section posteriorly. It is dense, and partially embraces the beginning of the axoneme and is structured in several thick longitudinal elements that are rods or laminae, according to the family. The microfilaments of the fuzzy coat are 30 nm long.

As we have previously observed, Isoptera show, in the various families, every kind of variation. First, none retains the conventional spermatozoon. The acrosome is consistently absent. The unique model of axoneme is that of the multiflagellate sperm of Mastotermitidae, and it is quite aberrant e.g., 9+0 without outer dynein arms. Moreover, few conventional mitochondria are present, and no accessory bodies. All the other, higher isopteran families have also lost the axoneme, and have aflagellate immotile sperm comprised simply of the nucleus and a few mitochondria. But Calotermitidae have evolved further and have several outpocketings of the plasma membrane that contain a rich cytoskeleton of microtubules. This group seems to be progressing toward a new motility. Evidently Isoptera separated from the blattoidean stock quite early, and have followed a long, drastic and independent evolution, attaining a series of synapomorphies unique in the Animal Kingdom.

Phasmoidea are in some ways more conventional, and certainly more homogeneous in sperm structure. Nevertheless the complex of synapomorphic characters is impressive: an acrosomal complex without a perforatorium, a lack of mitochondria, and consequently a peculiar axonemal metabolism and 17 protofilaments in the accessory tubules, enormous accessory bodies comprised of cytokeratin. In comparison with all the orders grouped in the classic blattoid-orthopteroid stock they are certainly the most highly evolved (Fig. 2).

In the paraneopteran orders sperm evolution seems to be even more dramatic but identification of the direction of the series of modifications is easier (Fig. 3).

Psocoptera are the first order of the group. They have a monolayered acrosomal complex, centrioles formed only of doublets, a 9+9+2 axoneme (one species with 13 protofilaments in the wall of accessory tubules) and two crystallized mitochondrial derivatives. The most primitive species have the usual single axoneme while others are more or less constantly biaxonemal. In fact the species belonging to Procomomorpha have almost all monoflagellate spermatozoa, while Trogomomorpha have one-fourth of the sperm in the ejaculate exhibiting two axonemes, and Troctomorpha have only biaxonemal spermatozoa. Mallophaga and Anoplura, orders that form with Psocoptera the homogeneous group of psocoid insects, have constantly biaxonemal spermatozoa, similar to those of the higher psocopterans. After these orders, where the biaxonemal condition seems to be affirmed, evolution follows two diverging branches. One of them concerns Thysanoptera, which reach a condition of three axonemes, arisen from three centrioles, mixed, disordered and incomplete. The acrosomal complex lacks a perforatorium. A single mitochondrial derivative with normal shape and crystal-

lization is present; accessory bodies are absent. Even if the sperm is motile, this organization suggests a tendency toward immotility. The second branch (Fig. 3) encompasses the order Hemiptera. Already in the suborder Heteroptera, Hemipterans show an important evolutionary progression with respect to the psocoid orders. First, the main pterygote characteristic of hyper-tely is accentuated (some species contain spermatozoa that are 5 mm in length, but are only 1 μ m wide). Therefore, the cytoskeleton of the sperm is drastically evolved. The acrosome, that can be very long, up to 2.5 mm, contains not only a strong actinic perforatorium, but also bundles of narrow microtubules. The axoneme, drastically 9+9+2, has accessory tubules that with respect to those of psocoids are larger and consist not of 13 protofilaments, but of 16, a number largely present among pterygotes. The two mitochondrial derivatives are enormous, strongly crystallized and contain at least three patterns of crystallization of the crystallomitin. As in polyneopterans, each mitochondrial derivative is linked to the axoneme by a delicate bridge. The retained psocoid characteristic is a tendency toward bi- or multi-flagellarity, that in some species seems to be constant, with one longer and one shorter axoneme, and toward the absence of accessory bodies.

In the suborder Homoptera (Fig. 3) sperm evolution reaches one of its highest expressions in the Animal Kingdom. In Auchenorrhyncha most of the heteropteran characters are retained. Important acquisitions are that the acrosomal complex appears devoid of a perforatorium and other cytoskeletal devices, large and peculiar accessory bodies are present and the tip of the tail is frequently branched. The shape of the accessory bodies offers excellent diagnostic characters reaching the specific level. The lower families of Sternorrhyncha continue showing the same general pattern as Auchenorrhyncha, even if Psylloidea have peripheral arborescent appendages that seem to have the same origin as the acrosome. The same appendages are present in the subsequent infraorder Aleyroidea whose mature sperm is immotile, lacks a true acrosome and axoneme and has two mitochondrial derivatives reduced to a pair of small granular bodies exhibiting no cytochrome-C-oxidase activity. The spermatid contains a 9+9+0 axoneme, a cap-shaped acrosome and normal mitochondria that are reduced or disappear at the end of the regressive spermiogenesis. Coccoidea are the last hemipteran infraorder. Their sperm is still devoid of an acrosome, mitochondria, centrioles and axoneme, and has regained motility by using the spermatid microtubular manchette, which is now transformed into a system of perinuclear parallel singlet tubules endowed with a series of single arms containing a MAP (microtubule associated) protein. Throughout Paraneoptera the possible evolutionary pathway of the sperm seems therefore to be complete. It extends from the classic typical pterigote sperm, to the biflagellate sperm, to the disordered axoneme with reduced motility, or to the hypertelic axoneme, followed by axoneme involution and loss, and finally by regained motility utilizing new devices.

Does a similar evolution occur in the enormous group of Oligoneoptera (holometabolic) insects? Here the phylogeny is less clear, and the general picture of the spermatozoon is more uniform. Nevertheless, interesting lines of evolution can be envisaged (Figs. 4-6). If we look for the presence of plesiomorphic characters, we see that oligoneopterans start with patterns similar to those of the lower forms of Apterygota and do not represent a further step after Para- or Polyneoptera (Fig. 1). In fact, we find examples of 9+2 axonemes, three-layered acrosomes and even biaxonemal forms that are close, therefore, to the very origins of terrestrial sperm evolution. The presence of such models has been sometimes interpreted as an example of highly

derived, regressive evolution, but given their frequency in a particular branch of oligoneapteran phylogeny, it also deserves to be considered as reflecting a basal position, without further speculations (Fig. 1).

The first group to be considered is the "panorpid orders", a group recognized by almost all insect phylogenists, and demonstrated only on spermatological basis by Baccetti⁶. These orders are Mecoptera, Aphaniptera, Diptera, Trichoptera and Lepidoptera (Figs. 1, 4, 5). In Mecoptera, Aphaniptera, primitive Diptera (the mycetophilid *Keroplatus*) and a few Trichoptera the axoneme is 9+2 and the mitochondrial derivatives are almost completely crystallized. The first character is an indication of plesiomorphic condition, and would indicate an ancestor of the group in the dipluran stock; the second indicates a more derived state. It places the origin of the group after the acquisition of crystallomitin, at least after the Zygaentoma branch off, and certainly after the branching of Palaeoptera, which are devoid of crystallized derivatives. I do not believe that the "9+2" of primitive panorpoids is a regression that occurred in their ancestry (i.e., an apomorphy) immediately after the long and complex acquisition of the "9+9+2" which promptly reappears in all the same panorpid orders with a clear synapomorphic process. It is rather possible that crystallomitin ancestor was already present during dipluran evolution together with the nine accessory tubules in the axoneme and that these characters were acquired and evolved in all lines derived from them, even though these were not affirmed in Palaeognatha. In fact, we have seen in most phyletic trends of Pterygota many instances of lost crystallization in mitochondria, usually occurring along with phenomena of axonemal regression.

Having noted the above, in panorpid evolution, both Mecoptera and Aphaniptera (Fig. 1) are "9+2" and have crystallized mitochondrial derivatives (one, crescent shaped in section, in the first order; two, one larger and cylindrical and the other smaller, in the second). The centriolar adjunct is present, even if short and caudally extended in a short process in some species. In Aphaniptera, moreover, two crystalline accessory bodies are extended for 500 μ m flanking the axoneme. The Diptera are another parallel branch arising from the panorpid tree (Fig. 4). There the Mycetophilidae family offers the key to the enigma (Fig. 4), having some species (*Keroplatus*) with a 9+2 axoneme as in Mecoptera and Aphaniptera. Only one partially crystallized mitochondrial derivative is present, the acrosome is monolayered and is devoid of a perforatorium, and accessory bodies are absent as in all Diptera. The whole family retains their character, but an important synapomorphy appears. The set of nine accessory axonemal tubules is progressively developed: they are zero in *Keroplatus*, two in *Tarnania*, seven in *Exechia*, nine in *Mycetophila* and *Leptomorphus*. Moreover, the wall of these singlets contains in section 15 protofilaments in some species and 16 in others. This observation substantiates the view that the mycetophilid tail retains plesiomorphic characters (and therefore the 9+2 is plesiomorphic) and that progressive acquisition of the 16 protofilaments is the most generalized, synapomorphic model in pterygotes. It would not be surprising to find some primitive mycetophilid species with 13 protofilaments (still retained by Tipulidae and Trichoceridae). Even in mycetophilids one species (the "fungus gnat" photographed by Phillips,¹¹) develops a 9+3 axoneme. From the Mycetophilidae line, after the definitive acquisition of the 9+9+2 number, but largely before the acquisition of the definitive 16 protofilaments in the wall of accessory tubules, a group of families branches off (Fig. 4). These families were suspected to be the most primitive of the order, but evidently the lower fungus gnats are even more so. These 9+9+2 fami-

lies are Tipulidac, Trichoceridae, Chironomidae, and Dixidae. The first two have 13 protofilaments in the accessory tubule wall; the latter two have 15. They have apparently branched off at different points of mycetophilid evolution. All have the classic dipteran sperm with the acrosome lacking a perforatorium, two largely crystallized mitochondrial derivatives and no accessory bodies. Other nematoceran Diptera lines have arisen from the mycetophilid stock. Sciaridae have the well known motile sperm with a monolayered acrosome and a single mitochondrial derivative. A giant centriole, gives rise to an axoneme comprised of approximately one hundred longitudinally arranged doublets with two dynein arms. Each doublet is flanked by an accessory singlet tubule having 13 protofilaments in the wall. It is possible that this peculiar line branched early from the mycetophilid line, together with the Tipulidae and Trichoceridae families which retain the 13 protofilaments in the wall of accessory singlets. Another line arisen very early from the basic stock is the Psychodidae. Here the more primitive Phlebotominae are evolving towards immotility, having a 9+9+0 axoneme and a single partially crystallized mitochondrial derivative, while the Psychodinae exhibit the described regressed aflagellate model with only one normal mitochondrion and a large acrosome. The most peculiar characteristic is that Phlebotomus has a recognizable subacrosomal perforatorium (the only example of a bilayered acrosome among dipterans). This, together with the pattern of regressive terminating in aflagellarity, suggests that Psychodidae branched out from ancestral dipterans before or at the beginning of mycetophilid evolution. Other Nematoceran families, branched off later from the mycetophilid stock, are evolving toward immotility. All have a monolayered acrosome and, at least in those examined so far, 15 protofilaments in the wall of the accessory single tubules. But while Bibionidae have a 9+0, or 9+9+0 axoneme (one empty central cylinder is present) and one well-crystallized mitochondrial derivative, Culicidae always have a 9+9+1 central rod in the axoneme and two derivatives while Simuliidae have a 9+9+3 axoneme and one derivative. Also, two crescent-shaped accessory bodies are present.

But the most spectacular evolution occurs in cecidomyid dipterans (Fig. 4). As noted above in the Cecidomyidae a primary step is the presence of one or two 9+0 axonemes lacking of dynein arms. In this category only the genus *Myricomyia* has one immotile 14+0 axoneme with armless doublets, and the species *Contarinia flori-perda* has an immotile 12+0 axoneme made up of armless doublets. All these taxa belong to the supertribes Oligotrophidi, Lasiopteridi and part of the Cecidomyidi. Around the axoneme (or axonemes) more or less numerous single microtubules which were part of the perinuclear manchette of the spermatid, are present. One species (see above) of the genus *Lestodiplosis* (also belonging to the Cecidomyidi) has a sperm (obviously immotile) completely lacking an axoneme and exhibiting single tubules. Therefore, with the total lack of an axoneme, immotility has been achieved. However, cecidomyid evolution progresses further. Many genera of the highest Cecidomyidi and the Asphonodyliidi have motile sperm where the manchette increases in the number of microtubules. The microtubules assemble two by two, forming doublets. Each doublet bears only a series of arms (apparently the outer) endowed with a single MAP (dynein) band. In the family therefore there is initially a regression, followed in *Lestodiplosis* by the complete disappearance of the classic motility apparatus (the two armed doublet), and finally the progressive reacquisition of a similar device by a different means, not involving the presence of a centriole.

Compared with the fantastic evolution and variation of Nematocera, dipterans belonging to the suborder Brachycera appear quite uniform. All have extremely long spermatozoa, from some hundred μm to a few mm (up to 6.64 mm in *Drosophila hydei*). The acrosome is monolayered and lacks a perforatorium, as in almost all dipterans. The plasma membrane is asymmetric, having an outermost layer 5 nm thick. There are two well-crystallized mitochondrial derivatives. Sometimes, as in *Drosophila melanogaster*, the derivatives are quite different in size, one of them being extremely small and short. The axoneme is 9+9+2, with two arms in the doublets, and 13 protofilaments in the wall of the accessory tubules. There is an abundant and dense intertubule material, including 13 protofilaments, and double spoke heads. These characters are very similar to those of trichocerid and tipulid nematocerans. Brachycera could have branched from the nematoceran stock at that level (Fig. 4).

Trichoptera and Lepidoptera are two related orders that also belong to the panorpoid group (Fig. 5). As proposed by Baccetti⁷, their sperm structure suggests that they could have arisen from a mecopteran-like ancestor. These two orders have many characters in common, first of all the heterogamety of the female sex. Large axonemal accessory tubules, filled with a glycidic material also are a characteristic common to the two groups. Trichoptera (Fig. 5) are usually assumed to be a less derived group, and their sperm structure substantiates this view. The suborder Annulipalpia is characterized by non-crystallized mitochondria, that are frequently conventional (or absent), by a monolayered (or absent) acrosome, and by the lack of accessory bodies. The axoneme shows the entire series of transformations already found in other groups with long and multiform evolution. A few species have the basic 9+2 axoneme, for example, a primitive hydropsychid, *Macronema*; others belonging to the genus *Polycentropus* have the 9+9+2 or 9+9+3 pattern, all with doublets having only the inner dynein arm. Other *Polycentropus* and *Hydropsyche* species have the strange 9+7 pattern, with immotile doublets lacking arms. Other Hydropsychinae have an aberrant immotile spermatozoon with no acrosome. The nucleus is lateral and several (more than 9) armless doublets arise from the basal body and individually protrude as single digitations from the cell body¹². Finally, aflagellarity is reached in the philopotaminid *Chimarra florida*, where the mature spermatozoon contains only elongate, horseshoe and apically annular in cross section nuclei, while the acrosomal complex and mitochondria are lacking. Conversely the suborder Integripalpia exhibits more conventional spermatozoa having a 9+9+2 axonemal pattern with monoarmed doublets, one mitochondrial derivative (always lacking crystalline material), and a monolayered, or absent at all, acrosomal complex. Dallai and Afzelius¹³ investigated the number of protofilaments in the accessory tubules, finding the basic number of 19, but variation from 19 to 16 along the length of each tubule. It seems therefore that Annulipalpia exhibit the entire range of character states (from 9+2 to aflagellarity) while Integripalpia have branched from the Annulipalpia line before regression of the motility apparatus, conserving the 9+9+2 constant structure. The similarity with nematoceran and brachyceran evolution is evident.

Lepidoptera sperm (Fig. 5) resemble trichopteran sperm in having large, more than 30 nm thick accessory tubules (with 16 protofilaments in their wall) in a conservative 9+9+2 axoneme. The acrosome is extremely reduced, monolayered and frequently absent. There are usually two mitochondrial derivatives that are partially crystallized, cristate, and unequal in size. Accessory bodies are absent. All Lepidoptera (including Zeugloptera and Monotrysia) have two kinds of spermatozoa: eupyrene spermato-

zoa that have a nucleus and are fertile; and the apyrene spermatozoa that lack a nucleus but play an essential although enigmatic role in the fertilizing ability of eupyrene sperm. Ditrysia are characterized with respect to the more primitive groups by having the glycocalyx of the eupyrene spermatozoa endowed with ordered, crystalline, laciniate or reticulate appendages. Therefore it is very clear that Lepidoptera branched from the trichopteran stock, conserving many trichopteran characters but immediately showing sperm dimorphism. Subsequently, ditrysians branched from monotrystsians, acquiring the laciniate glycocalyx. No evolution towards immotility and aflagellarity seems to have occurred.

The other important group of Oligoneoptera comprises the neuropteroid orders (Fig. 6). The most primitive order is Megaloptera (Fig. 6), showing many characters typical of highly derived Pterygota sperm, and found in Polyncoptera and Parancoptera i.e., three-layered acrosomal complex, 9+9+2 axoneme with two-armed doublets and 16 protofilaments in the wall of accessory tubules, two crystallized, large mitochondrial derivatives, and two accessory bodies. Raphidioptera (Fig. 6), the second neuropteroid order, contains a bilayered acrosomal complex and lacks the extra-axonemal layer. Other raphidiopteran characters are similar to those of Megaloptera. Neuroptera (Fig. 6) are quite similar to the two other orders: the acrosomal complex is very unstable, varying from the three-layered model of *Myrmeleon* to the complete absence of one in *Chrysopa*. The two mitochondrial derivatives are sometimes similar, but sometimes are of different sizes.

This classical sperm model also seems to be present in the other neuropteroid order, Strepsiptera (Fig. 6). Here the axoneme has the 9+9+2 pattern with biarmed doublets and two mitochondrial derivatives, partially crystallized and rich in cristae. The acrosomal complex is monolayered and there are no accessory bodies. Strepsiptera, for these reasons, seems to be a rather homogeneous group, and to have an independent position in the neuropteroid phylogeny.

Coleoptera (Fig. 6) maintain most of the typical neuropteroid characters but, as expected in such a large and diversified order, also show the signs of a long evolutionary history. They branch from the neuropteroid line, retaining a typical acrosomal complex comprised of acrosome and perforatorium (sometimes an extra-acrosomal layer is present), a 9+9+2 axoneme (biarmed doublets and 16 protofilaments in the accessory tubule walls), and two largely crystallized mitochondrial derivatives with cristae localized at the periphery. This structure is, e.g., present in adephagid Cicindelidae, in Carabidae, in the paired sperm of Ditiscidae where the sperm are accompanied by two crystalline accessory bodies and a single perflagellar body derived from the centriolar adjunct. Sperm structure in Cicindelidae is more or less conserved in polyphagid Scarabeiformia and in Bostrychiformia, all of them devoid of accessory bodies and a perflagellar body. But the Staphiliniformia exhibit a level of evolutionary diversity that is exceptional among Coleoptera: Staphilinidae supplement the basic organelles with a perflagellar body, originating from the centriolar adjunct, and two accessory bodies that have more or less the same tail structure seen in the Ditiscidae; Silphidae lack accessory bodies and retain the perflagellar body; the same occurs in the ptiliid *Ptinella* (1.4 mm long spermatozoon!) and probably in *Bambara*, where organelles are arranged in a complicated coiled structure. But in the same family, *Acroticus* is aflagellate, and retains mitochondria and a three-layered acrosomal complex, and *Actinopteryx* in addition, lacks a perforatorium and mitochondria.

A peculiar evolutionary progression also has occurred in the coleopteran group Cucujiformia. This group starts with Cleroidea

that has a three-layered acrosomal complex, a 9+9+2 axoneme, no perflagellar body, two crystallized mitochondrial derivatives and two accessory bodies. Cucujoidea have these same characters, but the acrosomal complex lacks the extra-acrosomal layer, and the two mitochondrial derivatives sometimes differ in size (Tenebrionidae). The group Chrysomeloidea has this same structure, but has quite highly derived accessory bodies, that differ structurally, each organized in two different regions (crescent-like, and "puff"-like). Among them, moreover, Cerambycidae and Bruchidae have a bilayered acrosomal complex and Chrysomelidae a three-layered complex. In the last families the subfamilies clearly differ for the sperm models, sometimes exhibit classic structure, but sometimes are biaxonemal (*Oulema*). In the subfamily Cassidinae the "puff"-like expansions of accessory bodies fragment into at least five subunits (Donacinae) and sometimes are extremely reduced (Alticinae)¹⁴. Finally, the group Curculionoidea contains species similar to the primitive Chrysomelidae, but also attains in the different subfamilies diverse models for the shape of accessory bodies and acrosomal the complex. Moreover, in Rhynchitinae and Attelabinae the axonemal pattern is "9+9+0"¹⁵. No aflagellate sperm have hitherto been described. Among Oligoneoptera, Hymenoptera (Fig. 6) have a doubtful position. Spermatozoa cannot clarify the problem. Sperm were examined only in a few species of Apocrita, and have a very conventional structure, clearly recalling that of derived coleopterans. They exhibit a bilayered acrosomal complex, 9+9+2 with armed doublets and 16 protofilaments in the wall of accessory tubules, two centrally crystallized mitochondrial derivatives (sometimes of different size), and two, frequently quite small, accessory bodies. More extensive investigation is needed for a definitive statement of the position of the Hymenoptera in the phylogenetic tree of pterygotes.

In conclusion the extremely varied and adaptive evolution of the insect spermatozoon seems to be strictly bound to the phylogenetic tree of the class. Many different systems of motility and egg penetration have been expressed. Each order has its spermatological story that seems to have reached a specific differentiation, giving unexpected and possibly important indications of the origin and evolution of the groups of orders, and of the lower taxa. Some general ideas that this chapter presents are that Protura have evolved independently from unknown ancestors, while Collembola and Japigid Diplurans retain the plesiomorphic characters of the primitive aquatic sperm. From Japigid Diplurans at least two lines of sperm structure are derived: one leads to Campodeid Diplurans, the second directly to the Panorpoid Oligoneopteran complex.

Campodeid Diplurans (or their ancestors) seem to have branched into two lines, one leading to the Thysanuran complex Archeognatha and Zygentoma, the other branching further towards the Palaeoneopteran complex (although extant Ephemeroptera and Odonata are quite different from one other) and towards the Paraneopteran complex, there giving rise to the many hemipteroid orders stopping. After the Thysanuran complex the sperm line seems to have branched further initiating the entire Polyneopteran group and the Neuropteroid complex of Oligoneoptera. Polyneoptera seems to have radiated from the Blattoid stock in many independent lines in which the primary steps seem to be the Gonwandian groups Grylloblattoidea, Cooloolidea, and Eumastacoidea. But Isoptera evolved as a totally separate group, passing through a long series of steps as Protura did among Apterygota. The Neuropteroidea group branched, giving rise to Megaloptera, Raphidioptera, Neuroptera, Strepsiptera, Coleoptera and perhaps Hymenoptera.

But only the sperm of Coleoptera followed long evolutionary path. The panorpoid line arisen directly from japedid ancestors, gave rise to several groups. Initial branches were some Trichoptera, Mecoptera and a few Diptera. From these branches the long lines of Trichoptera, Lepidoptera, Mecoptera, Aphaniptera, and the enormous order Diptera evolved. The view presented herein introduces several new interpretations of insect phylogeny: Polyneoptera, Paraneoptera, panorpoid and neu-

ropteroid complexes seem to have arisen independently from different apterygotan ancestors; Oligoneoptera seems an artificial, polyphyletic group, while Polyneoptera and Paraneoptera seem to maintain their consistency and monophyletism. Moreover as partially presented by Omodeo et al.¹⁶ hemimetabolic and holometabolic insects seem to have similar rank with none being more evolutionary derived than the other.

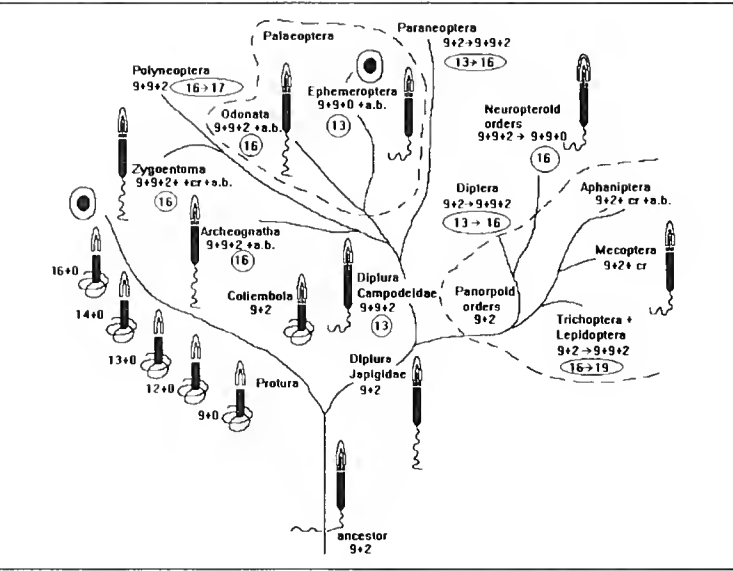

Fig. 1 - A scheme of insect sperm evolution. The symbols represent the elongate, flagellate or, alternatively, the roundish, aflagellate models. The number of layers of the acrosomal complex, as well as the presence of a perforatorium, are designed on the top of the dense nucleus. The axoneme pattern (9+2, 9+9+2, and variations), the presence of crystallomitin in mitochondria (cr), of accessory bodies (a.b.), and, encircled, the number of protofilaments in the accessory tubules (13, 16 a.o.) are also indicated. The further evolution of Polyneoptera, Paraneoptera, Diptera, Trichoptera, Lepidoptera and Neuropteroids is schematized in Figs. 2-6. (From Baccetti, 1).

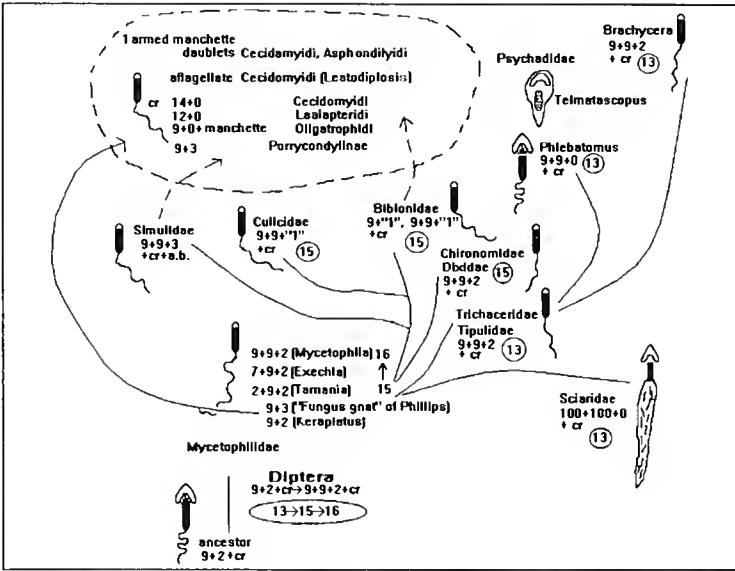

Fig. 4 - Scheme of the evolution of sperm structure in the order Diptera. Observe the enormous variability in axoneme pattern and in the number of protofilaments in the accessory tubules. The mycetophilid *Keroplatus* is the most primitive. From this position *Cecidomyiidae* could have arisen (solid arrow). Other possible origin for this family could be from positions close to *Simuliidae* or to *Bibionidae*. (From Baccetti, 1).

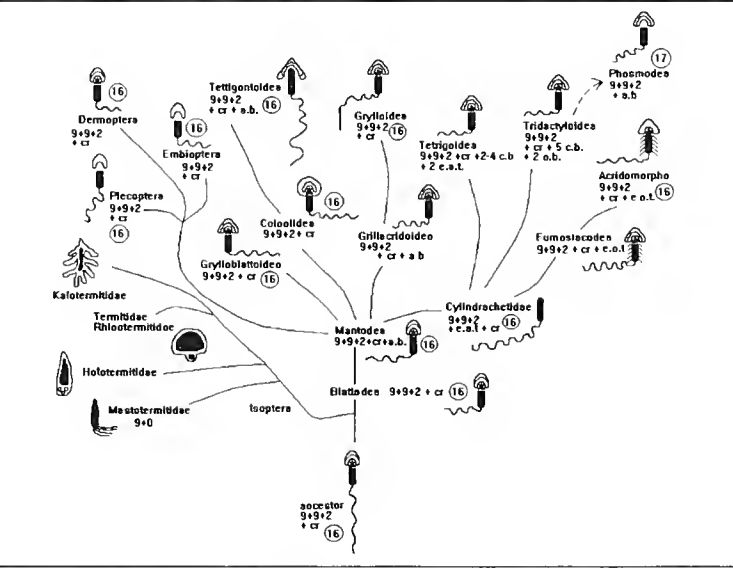

Fig. 2 - Scheme of the sperm evolution in Polyneoptera orders. Symbols are as those in previous schemes. The 9+9+2 pattern, and 16 protofilaments in accessory tubules are generalized. Aflagellarity is limited to the order Isoptera. (From Baccetti, 1).

Fig. 5 - Scheme of the sperm evolution in the two groups Trichoptera-Lepidoptera. Symbols are as in previous schemes. The generalized monolayered acrosome, and the lacinate appendages surrounding the ditrysian sperm are represented. (From Baccetti, 1).

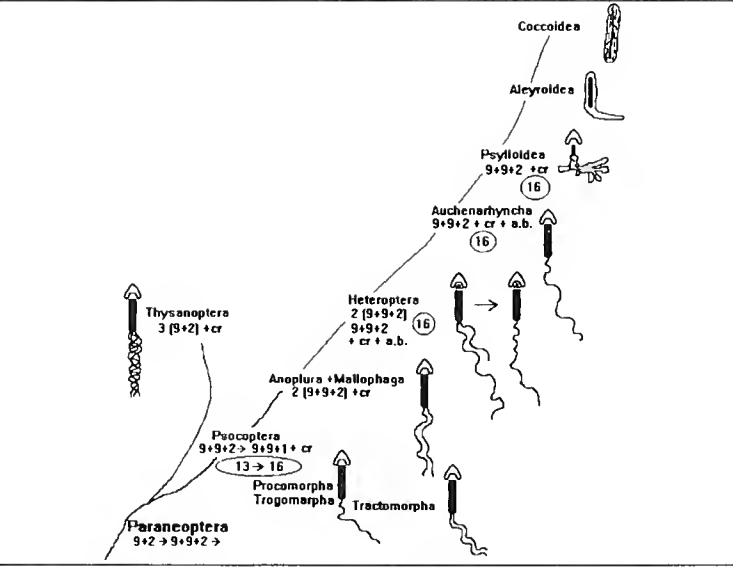

Fig. 3 - Scheme of the sperm evolution in Paraneoptera. The three- or biflagellarity in primitive orders, and the progressive realization of aflagellarity in Homoptera are evident. (Original).

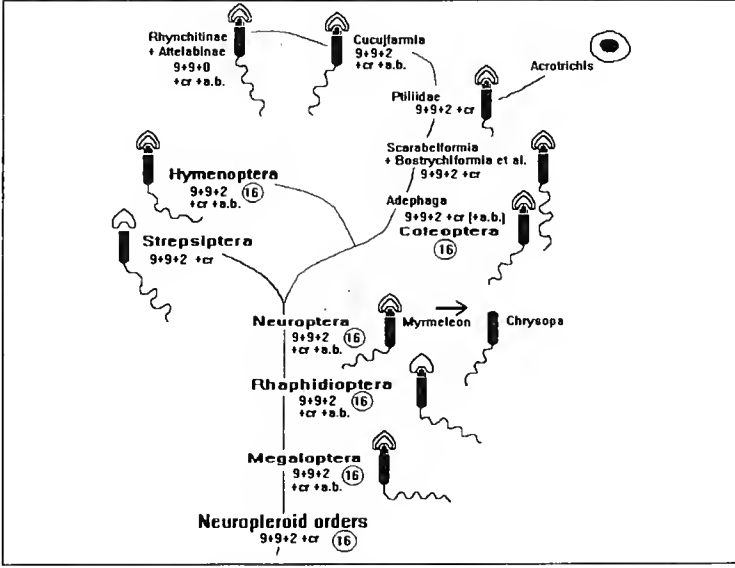

Fig. 6 - Scheme of the sperm evolution in Neuropteroid orders. The group is clearly homogeneous. Only at the top of Coleoptera a few subfamilies having 9+9+0 axonemes, or aflagellate spermatozoa are recorded. (From Baccetti, 1).

MOLECULAR POLYMORPHISMS
AND RATES OF EVOLUTION

Francisco J. Ayala

University of California, Irvine, USA

The hypothesis of the molecular clock proposes that rates of molecular evolution are stochastically constant. There is some debate as to how accurate the molecular clock is. It is generally agreed that the variance of evolutionary rates is larger than would be expected by chance, assuming that the probability of nucleotide or amino acid substitution remains constant through time for a given gene or protein. But some authors note that, nevertheless, the fit between the observed and expected number of substitutions is generally good enough, so that the assumption of a clock may be used to make decisions concerning the topology of a phylogeny and the timing of phylogenetic events.

I will, first, present data showing that the evolution of the Cu,Zn superoxide dismutase (SOD) appears to be so erratic that it would lead to erroneous phylogenetic inferences, even after standard corrections are made to account for superimposed and back substitutions. Second, I will extend the SOD analysis to a diverse set of 67 species and show that, if certain restrictive assumptions are made, it is possible to conclude that SOD evolves at a fairly constant rate. An important handicap, however, is that the parametric values of the restrictive assumptions can be estimated only empirically and require large data sets. Hence, phylogenetic inferences based on a limited, or not very diversified number of species may well be in error. Third, I will present data showing that the evolution of glycerol-3-phosphate dehydrogenase (GPDH) is erratic but in a very different manner from SOD. Indeed, in the genus *Drosophila*, the GPDH clock appears to be stuck over an evolutionary span in terms of millions of years (My).

The erratic SOD clock - The superoxide dismutases are essential in the defense of organisms against the toxicity of oxygen. In *Drosophila melanogaster* SOD is a dimer molecule made up of two identical polypeptides, each consisting of 151 amino acids and with a molecular weight of 15,750 daltons. The number of amino acid differences between eight diverse organisms is given in Table 1. These organisms belong to two different kingdoms, fungi and animals, that diverged from each other more than one billion years ago. The fungi include the two remotely related yeast and mold; the animals include an insect, a fish, and four mammals.

Table 1. Amino acid replacements between the SOD sequences of eight organisms

	Rats	Horse	Cow	Fish	Fly	Yeast	Mold
Human	25	30	26	48	58	69	69
Rat		28	23	49	59	63	69
Horse			27	48	61	65	69
Cow				41	60	68	65
Fish					61	67	65
Fly						69	65
Yeast							47

The eight organisms share the same residue at 55 (38.2%) of the 144 sites common to all the sequences. This degree of conservation

is typical of slowly evolving proteins, such as cytochrome *c*. This conjecture of slow evolution is, however, not confirmed when it is noticed that the four mammals, whose ancestral lineages diverged from each other within the last 75 My, share the same amino acid in only 108 (72.5 percent) of their 149 common sites. This is a degree of homology characteristic of very fast evolving proteins.

The phylogenetic history of the eight organisms is shown in Fig. 1. There can be little doubt that the topology of the figure is correct; that is, that the order of branching of the various lineages is as indicated in the figure. The times of divergence shown are less certain. The divergence between the two ungulate lineages or between the rodent and the primate lineages is given as 63 My ago, a figure accepted by paleontologists with a likely error of less than five My. The most recent ancestor to the four mammal lineages is placed at 75 My, a value that could be in error also by a few, but probably no more than 10 My. The divergence between the fish and mammal lineages is placed at 450 My, near the beginning of the Silurian; the ray-fin fishes ancestral to modern fishes and the lobe-fin fishes from which the terrestrial vertebrates derived are already present in the Silurian and become common in the Devonian fossil record. The arthropod and vertebrate lineages had diverged by the beginning of the Cambrian, 570 My. The divergence time of 600 My may be an underestimate, but it is unlikely that it would be by more than 100 My. More tentative yet are the divergence times between the yeast and the mold, given at 600 My on the basis of protein sequence data that assume the molecular clock; and between the two kingdoms, animals and fungi, given as 1,200 My, a figure that could be off by as much as 200 My.

The topology of the phylogeny shown in Fig. 1 makes it possible to group comparisons between pairs of species that are separated by equal lengths of evolutionary time. This has been done in Table 2, where the amino acid differences per hundred residues are given. The corrections are made by the method of Dayhoff (1978, Table 36) but corrections made by other methods, whether for amino acids or for nucleotides do not change in any substantive way the normalized values (Ayala 1986). Cytochrome *c* differences are given for comparison.

It is apparent in Table 2 that there are large discrepancies between the number of amino acid replacements and the times since the divergence of the lineages. This disparity is further exposed by contrasting SOD and cytochrome *c*. The corrected values are fairly similar when we compare the fungi and the animals (58 and 66, respectively); for the comparison between the ungulates, the SOD value is nearly seven times larger than the cytochrome *c* value (19.5 vs. 2.9). Clearly, SOD is not evolving with the kind of regularity seen in cytochrome *c*.

The disparity between the rates of evolution in different lineages and/or different times is further displayed in Fig. 2. When the average differentiation between all four mammals is examined, the rate of amino acid substitution per 100 residues per 100 My is 27.8, a fairly fast rate of evolution. The distances between the swordfish and the mammals or between any of them and *Drosophila* give a rate of evolution of 9.1 amino acid substitutions

per 100 residues per 100 My, which is fairly slow. A very slow rate of evolution is obtained from the distances between the animals and the fungi: 5.5 amino acids per 100 residues per 100 My, similar to the rate obtained when the same comparisons are made for cytochrome *c* (see open circle in the figure), which is a very slowly evolving protein.

Fixing the SOD clock - Fitch and Markowitz (1970) introduced the concept of *covarions* (*concomitantly variable codons*), which asserts that there is a limited number of amino acid sites that can be replaced at any time in a given lineage. The number of sites that can vary remains constant, but the composition of the set varies through time and in different lineages. The application of this assumption to a particular protein requires that we determine (1) the size of the covarion set, i.e., the number of sites at which replacements can occur at any given time in a given lineage; (2) the total number of sites that are variable, i.e., the number of sites, if any, at which amino acid replacements can never occur in any lineage; (3) the number of different amino acids that can occur at the variable sites, which may range from only two different amino acids tolerated at some sites (for example, at a site that must have a negative charge only aspartate and glutamate can occur) to all 20 amino acids; (4) the persistence of the covarion set, i.e., the rate at which one site in the set becomes replaced by another site; and (5) the rate of amino acid replacement. The analysis of 67 SOD sequences from very diverse organisms makes possible to estimate the values corresponding to the five parameters defined in the previous paragraph as follows (Fitch and Ayala 1994): (1) the number of covarions is 28; (2) the number of codons that are permanently invariable across the range of taxa from fungi to mammals is 44; (3) the average number of amino acids that can occur at a variable site is 2.5; (4) the persistence of the covarion set is 0.01; and (5) the rate of amino acid replacement is 0.6 per million years. Table 3 shows that a reasonably good fit is obtained between the observed number of amino acid differences among sequences and the number expected when a molecular clock is operating with the constraints defined by the parameter values just given.

The conclusion derived from the previous analysis is that SOD may be evolving at a constant rate as postulated by the molecular clock, even though it appeared at first quite unreliable because the constraints under which the clock operates had not been taken into account. This conclusion must, however, be tempered by two considerations. The first is that the determination of the components of the clock (such as number of covarions, total set of variable sites, persistence, and number of alternatives allowed per site) requires a very large data set, which may not be available in a particular study. The second consideration challenges the statistical validity of the grounds for accepting the conclusion that a clock is operating, namely the agreement between the observed and expected number of amino acid replacements (Table 3). When the numbers of parameters to be estimated is as large as five and the values that

the parameters can take are not severely constrained, it is small wonder that a reasonable agreement is obtained between the observed values and the expected values so freely estimated.

In any case, a note of caution must be advanced. Inferences of divergence time between lineages derived from a particular clock cannot be assumed to be correct unless the relevant components of the clock have been ascertained. The apparent rate of SOD divergence observed among mammals or flies would yield grossly erroneous time estimates when simply extrapolated to the differences observed between the vertebrate classes (fish versus tetrapod or amphibian versus mammal) or between metazoans and fungi. The SOD “clock” is a complex of several component parts that interact with each other and are subject to various constraints.

Table 3.
Paleontological dates and number of replacements for comparisons between the SOD sequences of 67 diverse species. “Replacements” are the numbers obtained by assuming 0.6 replacements per million years. The expected values are derived from 40 computer simulations for each entry

Comparison	My	Replacements	Amino acid differences	
			Observed	Expected
<i>D. nebulosa</i> - <i>D. melanogaster</i>	55 ± 5	33	8 ± 12	8 ± 12

The GPDH spastic clock - The enzyme GPDH plays a crucial role in metabolism through its keystone position in the glycerophosphate cycle, which provides energy for flight in the thoracic muscle of *Drosophila* flies. We have obtained in my laboratory the nucleotide sequence of 18 fruitfly species of which 14 species are of the genus *Drosophila*, one species of *Zaprionus* (these 15 species will be referred to collectively as *Drosophila*, since phylogenetically *Zaprionus* falls inside the *Drosophila* cluster), 2 species of the closely related genus *Chymomyza*, and the medfly *Ceratitis capitata*, which belongs to the family *Tephritidae*. Table 4 gives the number of amino acid differences and the nucleotide distances between species, based on 768 coding nucleotides (out of 831 in the complete sequence). The nucleotide distances are estimated using Kimura’s two-parameter method.

There are three triplets of closely related taxa that belong to the same species group: *melanogaster* (1-3), *obscura* (4-6), and *willis-toni* (7-9). The time since the divergence of the species of the same

Table 2.

5. Yeast to mold	30.7 (1.8)	39.4 (2.0)	37.5 (13.0)	52.5 (18.2)	600 (9.5)
6. Fungus to animal	44.6 (2.6)	66.2 (3.4)	40.9 (14.2)	58.0 (20.0)	1,200 (19.0)

Figure 1. Phylogenetic relationships among eight organisms with the approximate time scale. The numbers along the branches of the phylogeny represent the inferred numbers of amino acid substitutions that have taken place per 100 residues in the evolution of SOD.

group is below 20 My; there are no amino acid differences among species of the same group. The time of divergence for all other *Drosophila* comparisons ranges from 40 to 65 My; the average number of amino acid differences is about 3, with little correlation between the divergence time and the number of differences, as it is apparent in Fig. 3 (left). The divergence between *Chymomyza* and the *Drosophila* species is estimated at 65 My; it occurred just about the same time as *D. lebanonensis* diverged from the other *Drosophila* species. Yet the number of amino acid differences between *Chymomyza* and *Drosophila* is about 8, more than twice the average number of differences among the *Drosophila* species. The divergence between *Ceratitidis* and the *Drosophilidae* occurred about 100 My; the number of amino acid differences is about 21, seven times larger than among the *Drosophila*.

The spastic character of GPDH evolution is shown in Fig. 3 (left). The rate of amino acid replacement per hundred million years is 2.1 for comparisons between *Drosophila* species, 4.4 between *Drosophila* and *Chymomyza*, and 10.3 between *Ceratitidis* and the *Drosophilidae*. The long-term rate of evolution of GPDH based on comparisons between species from three animal phyla (insects, mammals, and nematodes) or from three kingdoms (animals, plants, and fungi) is approximately the same as between *Ceratitidis* and *Drosophila*, about 10 replacements per hundred million years. The pattern of GPDH amino acid evolution over time is,

Figure 2. Rate of amino acid substitutions per 100 residues in the evolution of SOD. From left to right, the solid circles represent, respectively, the average differentiation between four mammals (70 My), between the swordfish and the mammals (450 My), between the fruit fly and the five vertebrates (600 My), and between two fungi and the six animals (1,200 My). The three straight lines give three different rates of evolution: 5.5, 9.1 and 27.8 amino acid substitutions per 100 residues per 100 My. The open circle represents the average differentiation between the two fungi and the animals for cytochrome c, a protein known to evolve at a fairly constant rate.

thus, the reverse of the pattern observed in SOD. In GPDH, the apparent long-term rate is about five times faster than the short-term rate; in SOD it is five times slower. It may be noticed that, nevertheless, the rate of nucleotide substitutions in *Gpdh* conforms fairly well to the expectations of the molecular clock (see Table 4, below the diagonal, and Fig. 3, right).

It may well be possible to fit the rate of GPDH evolution to the hypothesis of the molecular clock by making an appropriate set of assumptions and estimating parameter values derived from the observations at hand. But will these assumptions and parameter values obtain when other taxa are investigated? The answer is “no,” at least in the case of GPDH. The rate of amino acid replacement between mammal species that diverged up to 65 My ago is much greater than between *Drosophila* species; rather, it approximates the long-term rate of GPDH evolution.

In conclusion, I will reiterate the point made earlier. The molecular clock is a powerful hypothesis when applied to the reconstruction of phylogeny. It may often be the most reliable among available sources of evidence, but it may also lead to very erroneous inferences. The molecular clock, to the extent that there is one, is a complex clock with various components and constraints that cannot be specified a priori, nor can they be extended from one to another group of organisms, much less from one to another gene.

INSECT EVOLUTIONARY BIOLOGY: LESSONS FROM DROSOPHILA

Jeffrey R. Powell

Department of Biology, Yale University, New Haven, USA

Drosophila have long served as a model organism for a wide variety of biological research especially in genetics and evolution. The popularity of this model has reached its highest peak in recent years with more scientists working on more different aspects of its biology than ever before. The fields of *Drosophila* development, neurobiology/behavior, and molecular biology have seen the greatest growth in the last fifteen years. The numbers of publications on *Drosophila* has been rising exponentially for the last 70 years with well over 70,000 published papers today. This growing knowledge will be particularly important in evolutionary studies as any full understanding of evolution must involve knowledge at all levels of biological organization. Reciprocally, evolutionary understanding can shed light on all the other fields because evolution is the organizing umbrella under which all biological information can be best understood. The purpose of this lecture is to review the present status of evolutionary studies on *Drosophila* and to emphasize generalities which are very likely to hold true for a large part of the class Insecta. A fuller account can be found in a forthcoming book titled *Progress and Prospects in Evolutionary Biology: The Drosophila Model* (to be published by Oxford University Press).

The genus Drosophila - When most biologists think of "Drosophila" they think of *D. melanogaster*, the most widely studied species. However, there are about 2,000 species in the genus that occupy virtually every region of the world with the exception of there being no truly Arctic *Drosophila*. The genus very likely originated in Southeast Asia some 60-70 mya (million years ago). There are three major subgenera of the genus: *Sophiophora* (about 300 species including *D. melanogaster*), *Drosophila* (about 700 species), and *Idiomyia* (800-1,200 species). The last is a monophyletic group of endemic Hawaiian *Drosophila* that has irradiated to form the greatest morphological and behavioral diversity of all the *Drosophila*. Interestingly, it split from subgenus *Drosophila* about 30 mya, thus predating existing islands (Powell and DeSalle, 1995). Most likely the colonization occurred on islands of the archipelago that are now submerged (Beverley and Wilson, 1985).

The larval breeding sites of *Drosophila* species are generally rotting, fermenting vegetation including fruits, stems, fluxes, leaves, bark, cacti, and fungi. Yeast and bacteria growing on these substrates are a primary source of nutrition. There also exist some bizarre species which breed in the spittle of spittle bugs (Cercopidae), nests of solitary bees, and parasitize spider eggs. Three independent times, a species has adapted to breeding in the nephritic groove of crabs (Carson, 1974). Perhaps the most unusual are seven species in Africa which predate aquatic larvae of blackflies and midges. Unfortunately, many of the most used species in laboratory research are those that have become adapted to human refuse and thus have rather boring ecologies. It needs to be emphasized that the species most studied in laborato-

ries are a small subset of species selected for those species easily available and able to breed on artificial food; these have most often been "garbage species" such as *D. melanogaster*.

Visible mutations - Early in the history of genetics, it was not clear whether the morphological mutants cropping up in laboratory cultures and being genetically studied were simply laboratory artifacts or actually exist in natural populations. A large number of studies have examined frequencies of visible mutations in natural populations and the general conclusion is that many of the laboratory-identified mutations can be found in nature, but their frequency is very low (Spencer, 1947). Approximately one visible mutation occurs per two haploid genomes in nature. The number of loci capable of producing a discretely visible phenotype is estimated to be about 2,000, so the average frequency in a natural population of any single visible mutation is about 0.00025. The message is that overwhelmingly, visible mutations are deleterious and never reach appreciable frequencies in populations. In light of recent molecular findings, this is not unexpected: most visible mutations are caused by insertion of a transposable element that destroys or radically alters gene function.

Molecular variation - Underlying this remarkable morphological homogeneity in *Drosophila* populations is a plethora of genetic variation. This was first demonstrated using allozymes when it was determined that about 50% of all loci studied are polymorphic for alleles in high frequencies and any individual is heterozygous at about 15% of all loci (Powell, 1975). It was clearly recognized that this must be a serious underestimate as only nucleotide changes that cause a change in electrophoretic mobility of proteins are detected. More recent DNA sequencing has confirmed this serious underestimate. Estimates of per nucleotide heterozygosity range from 0.5 to 1% for coding DNA, and 1 to 2% for non-coding DNA (Moriyama and Powell, 1996). In *Drosophila* 98% of the genes are over 200 bp with a mean of about 1,700 bp (coding region only). This means, that in addition to every individual being genetically unique, *each is heterozygous at virtually all loci!* Of course, it remain to be shown how much of this nucleotide variation has adaptive meaning, although the growing evidence is that much of it is subject to selective forces, even synonymous mutations that do not affect proteins.

Inversion variation - A special type of naturally occurring variation that is especially ubiquitous and important in *Drosophila* are chromosomal inversions, especially paracentric inversions (Krimbas and Powell, 1992). Of the species examined, 58% (106/183) are polymorphic for naturally occurring inversions. The knowledge of inversions in *Drosophila* is greatly aided by the giant polytene chromosomes. I suspect many other insects would be equally variable for these variants if they were examined and

favorable cytogenetic material were available.

Two aspects of inversions are especially important: (1) they suppress recombination within the breakpoints and (2) they are often under extremely strong selection. If one is working with a species and is not aware of the presence of inversions, considerable misinterpretation of data might ensue because of these two properties. For example sequencing a gene for systematic purposes could be very misleading if unbeknownst to the researcher, that gene is within an inversion (e.g., Powell, 1991).

Speciation - Considerable progress has been made in understanding the genetic basis of speciation in *Drosophila* (Coyne, 1992). Several points are especially worth noting. First, multiple examples exist of cases of either pre-mating or post-mating isolation occurring first in the speciation process; there seems to be no general rule. Second, Haldane's rule holds very well in *Drosophila*: in interspecific hybrids, if only one sex is sterile or inviable, it is the heterogametic sex (males). Third, when post-mating isolation is the first step in speciation, male sterility is the most frequent form. Fourth, the genetic cause of sterility is most often highly multigenic while inviability may have a less complex cause, i.e., fewer genes are involved (Wu and Davis, 1993). The X chromosome has a disproportionate effect for both sterility and inviability likely due to recessive mutations being expressed in the hemizygous heterogametic sex. Fifth, exceptions to highly multigenic causes of reproductive isolation may occur for behavioral isolation where single genes may have a major effect on courtship song or pheromone production. Sixth, founder effects are one documented population process that can start the speciation process; most often the first isolation induced by founder effects is premating isolation (Powell, 1989). Following a founder event, often the mating discrimination is asymmetric with derived females displaying less discrimination against ancestral males than do ancestral females discriminate against derived males (Kaneshiro, 1976).

Phylogenetics - Given the large number of species in a single genus, the small size, and relative lack of morphological variation, it is not surprising that understanding of the phylogenetic relationships among species and species groups is very incomplete. However, considerable progress has been made recently by using DNA data to construct molecular phylogenies (Powell and DeSalle, 1995). Such phylogenies can be helpful in understanding evolutionary principles. As just three examples in *Drosophila*, we can demonstrate (1) that chromosomal arm fusions are much more common than fissions, (2) intron loss is most often a derived character for a gene, and (3) transposable elements can be transferred across species boundaries.

Genome evolution - Genome size in *Drosophila* varies by about a factor of six. By far the majority of change occurs for heterochromatin. There is no correlation between body size and genome size. Chromosomal arm content has remained remarkably constant through the evolution of the species with the same genes remaining on the same arm, although arms are rearranged by paracentric inversions. The evolution of sex chromosomes can be studied in *Drosophila* as there are cases where former autosomes have become attached to a Y chromosome. Such autosomes begin to become genetically inactive due largely to the accumulation of transposable elements (Steinemann et al, 1993). The homologue of the attached autosome becomes a neo-X because it is hemizygous in males; it evolves dosage compensation.

Molecular evolution - As previously mentioned, *Drosophila* have been well-studied for naturally occurring molecular variation, with considerable being found. An exception to high levels of nucleotide variation is for regions of the genome with very low recombination, e.g., the non-recombining dot fourth chromosome of *D. melanogaster* has no documented variation (Berry et al, 1991). This is likely due to hitchhiking effects caused by either selective sweeps of advantageous variants or selection against chromosomes with deleterious mutations. X-linked genes are less variable than autosomal genes, likely because the population size of X chromosomes is 3/4 that of autosomes. Polymorphisms involving transitions outnumber those for transversions, likely because of the structure of the genetic code: transitions are more often synonymous substitutions than are transversions. Codon usage bias is often extreme in *Drosophila* and specific to certain codons. A single gene (e.g., *Alcohol dehydrogenase*) may display phylogenetic persistence of avoidance of codons throughout the genus. It is impossible to explain the pattern of codon usage bias in *Drosophila* without invoking a role for natural selection detecting these mutations.

In comparing patterns of variation within and between species, differences are seen in the level of synonymous and replacement changes. The ratio of these is higher within than between species (McDonald and Kreitman, 1991). A possible explanation is that replacement mutations are either deleterious and quickly eliminated; or they are advantageous and quickly swept to fixation. In either case they are unlikely to be observed in a polymorphic state. Synonymous mutations are closer to neutral and thus can remain polymorphic in a population for longer periods and thus likely to be observed as polymorphisms.

Development - While considerable progress has been made in understanding the molecular and genetic control of early development in *Drosophila*, little has been learned about the evolution of development. One problem has been that the majority of work has been done on early development when the overall *Bauplan* is laid down. From species comparisons, this appears to be invariant throughout the genus. To find significant variation it has been necessary to go outside Diptera, which makes evolutionary comparisons very difficult. To understand the evolutionary history of traits one needs closely related monophyletic lineages such as exist within *Drosophila*, where no variation has been found. It is likely that the majority of diversity in *Drosophila* is caused by later stages of development which have not been well-characterized. It is also possible that little or no variation in the early stages of development is due to the fact that all the molecular probes and theoretical orientation have been derived from a single species, *D. melanogaster*. If other species were using different developmental programs, would we recognize it?

Phyletic phenocopies - More interesting from an evolutionary standpoint has been the suggestion that some of the diversity of *Drosophila* is due to rather simple changes in major genes. The concept of phyletic phenocopies states that different lineages may differ by traits known to be mutants in one species. This not only helps in understanding the possible genetic basis of morphological diversity, but also may help in systematic studies. Examples include Hawaiian *Drosophila* (DeSalle and Carew, 1992): the broad head of *D. heteroneura* is similar to *Deformed* and *labial* mutants of *D. melanogaster*; the modified mouth parts group resemble *proboscipedia* mutations; the modified tarsi group have appendages similar to *Distal-less* mutations. The absence of interfacetal setae was once used as evidence that Hawaiian *Drosophila* do not belong in the genus *Drosophila*, but

once it was recognized that mutations in the single gene *Hairless* can give rise to that trait, its importance as a phylogenetic character was downgraded.

This very brief survey of recent, and some not so recent, advances in knowledge of *Drosophila* evolutionary biology should give some indication of the richness of the studies on this

single genus. Many of these findings have general applicability to all animals, more to all insects, and even more to all Diptera. I urge you to look to the *Drosophila* literature for guidance as to how to approach your own particular problem and what you might expect to find. *Drosophila*, too, is an insect.

LIFE HISTORY EVOLUTION IN INSECTS: THE ROLE OF THE PHENOTYPE IN EVOLUTIONARY THEORY

Stephen C. Stearns

Zoology Institute, University of Basle,
Basle, Switzerland

Great theories make surprising predictions. By adding phenotypes to evolutionary theory, life history evolution extended the range of predictions from hard-to-measure genetic patterns to easier-to-measure whole-organism traits directly connected to fitness. It has successfully explained: why organisms are small or large, why they mature early or late, why they have few or many offspring, why they have a short or a long life, and why they must grow old and die.

This talk has four parts. I will first review how life history theory explains the evolution of (1) age and size at maturity, (2) reproductive investment, and (3) lifespan and ageing, then (4) give you some evidence and concluding thoughts on two concepts in life history evolution that are not yet fully understood: tradeoffs and phylogenetic constraints. You will see that theoretical biology has produced surprising insights confirmed by successful quantitative predictions, that life history evolution plays a central role in evolutionary theory, that tradeoffs and constraints remain a problem, and that evolution is becoming a great scientific theory with the same status as physics.

(1) *Age and size at maturity* - Age and size at maturity are optimized when the benefits and costs of maturation at different ages and sizes balance at a stable equilibrium point or along a reaction norm. We start with an abstract picture of a life history, define the costs and benefits of delaying maturity, model optimum age and size in one environment, then extend the model to reaction norms for age and size in changing environments. This example makes three important points: (a) the quantitative predictions were successful, (b) the modeling procedure was simple, and (c) traits involved in tradeoffs contribute most to fitness at intermediate values.

(2) *Optimal clutch size and reproductive investment* - David Lack pointed out that if nestling survival decreases linearly as clutch size increases, then an intermediate number of eggs produces the most fledglings. He was right in theory, wrong on the details, but he got the main point: fitness is often maximized at intermediate reproductive investments. Some of the best recent work on clutch size has been done on kestrels in The Netherlands. If kestrels lay the optimal clutch, then larger or smaller clutches should have lower fitness than the one actually laid. When Serge Daan, Jos Tinbergen, and Cor Dijkstra manipulated clutch size in kestrels, they found that kestrels optimize their reproductive investment with clutches of intermediate size. This confirmed Lack's view, and their work also showed that if you want to measure reproductive costs, you have to be prepared to follow individuals for at least two generations, for many of the costs are paid by the offspring.

The problem of clutch size can be generalized to the problem of predicting the optimal allocation to reproduction over the entire lifespan. This is referred to, in life history theory, as The

General Life History Problem or as The Reproductive Effort Model. Some important predictions of the Reproductive Effort Model: (a) if mortality rates increase in one adult age class, then the optimal reproductive effort increases before that age and decreases after it (Michod 1979); (b) if adult mortality rates increase, the optimal age at maturity decreases (Roff 1981); and (c) if mortality rates increase in all age classes, then optimal reproductive effort increases early in life and optimal age at maturity decreases (Charlesworth 1980). Now let us consider two tests of these predictions:

the first test was done by David Reznick, John Endler, and their colleagues, who changed guppy mortality rates for 13 years by manipulating predators in the field in Trinidad. The guppies responded to increased mortality by maturing earlier at a smaller size and producing more, smaller offspring when raised under constant conditions through two generations in the laboratory (the changes were genetically based). Evolution happened very fast - these differences were significant within 50 generations.

A second test is currently being carried out in my laboratory. It involves a selection experiment on *Drosophila*, and the part of that experiment that tests The Reproductive Effort Model consists of two treatments each with three replicates. The first treatment is high adult mortality - 90% of the flies in the cage are killed and replaced twice per week; the probability of surviving one week as an adult is 0.01. Juvenile mortality is about 96.6%. The second treatment is low adult mortality - 20% of the flies in the cage are killed and replaced twice per week; the probability of surviving one week as an adult is 0.64. Juvenile mortality is about 99.2%. Under the high adult mortality treatment, the main problem faced by the flies is to achieve peak fecundity at 14 days of age when they enter the cage with only 24 hours to live. At 25° they normally achieve peak fecundity at 15-16 days. Thus they need to move that peak forward 1-2 days, and one way to do so is to accelerate development and eclose earlier at a smaller size.

Results of the selection so far: (1) females from the high adult mortality treatment develop 9-12 hours faster than females from the low adult mortality treatment, are about 3% lighter, have higher fecundity early in life and lower fecundity later in life. Males from the high adult mortality treatment develop 14 hours faster but do not weigh less than males from the low adult mortality treatment, suggesting that the age-size tradeoff itself has evolved to compensate. This is precisely what was predicted by The Reproductive Effort Model.

(3) *Reproductive lifespan and ageing* - Reproductive lifespan is a balance between selection to increase the number of reproductive events per lifetime and effects that increase the intrinsic sources of mortality with age. The first lengthen life, the second shorten it. Part of the increase in intrinsic mortality rates with age is due to tradeoffs common to all members of a species

(physiology caused by phylogenetic constraints) and part is due to the genetic effects that result in ageing or senescence. The process that produces an optimal lifespan given phylogenetically fixed tradeoffs works like this: selection pressures that lengthen life decrease the value of offspring and increase the value of adults. These include lower adult mortality rates, higher juvenile mortality rates, and increased variation in juvenile mortality rates from one reproductive event to the next.

In addition to the optimisation of the lifespan through life history evolution, we must also take into account the evolution of ageing. Organisms that reproduce sexually, have a clear separation of germ line from soma, and return to a single-cell stage at some point in their life cycle must age. Organisms that reproduce by simple division should not age. The evolutionary theory of ageing starts by observing that selection pressures drop with age; sufficiently old organisms are irrelevant to evolution. This fact has two consequences: first, genes with positive effects early in life and negative effects late in life are selected for and accumulate in the genome. Their effects are called antagonistically pleiotropic. Second, more deleterious mutations should accumulate and be maintained by selection-mutation balance when they are only expressed in older, rather than younger, age classes, for in older ages the force of selection is smaller and allows the accumulation of more mutations in a classical mutation-selection balance. Thus ageing is seen by evolutionary theory as a byproduct of selection for reproductive performance. It arises through the accumulation of many genes that have positive or neutral effects on fitness components early in life and negative effects on fitness components late in life.

Drosophila is one of the most important model systems for the evolution of ageing. Experiments on *Drosophila* suggest that early and late fitness components do trade off, but whether lifespan trades off with early fecundity or with age and size at maturity depends on the treatment and the lab doing the work.

(4) *Some observations about tradeoffs and phylogenetic constraints* - We do not yet have a single case in which the major

causes that determine tradeoffs have been separated experimentally to estimate their relative importance. Those causes include phylogenetic heritage, primarily expressed as development and physiology common to all individuals in a species, and genetic variation among individuals. We have performed a genetic engineering experiment in which we appear to have revealed the influence of phylogenetic constraints while investigating the impact of genetic variation. Those manipulations revealed the same sorts of tradeoffs that one finds in selection experiments. This raises an important question: is the expression of genetic variation influenced by the “fixed” part of the genome, by physiology and development? If it is, that would explain the origin and impact of phylogenetic constraints.

Life histories are probably not the best system in which to ask this question at the moment. A better one is the patterning of butterfly wings, a system currently being developed by Paul Brakefield, Vern French, and Sean Carroll.

Some points to remember - (1) Traits were analyzed one-by-one: age and size at maturity, reproductive investment, lifespan and ageing. (2) The analysis was done in terms of mortality rates, fecundity rates, and tradeoffs. (3) Reliable studies have shown important tradeoffs among age and size at maturity, reproductive investment, and lifespan. (4) These tradeoffs are the basis for coordinated syndromes of life history traits - not habitat templates, not r&K selection.

Conclusion - Life history traits determine fitness. Individual variation in life history traits is natural selection. Life history evolution has a central place in evolutionary theory because it makes clear the mechanism of natural selection and the potential reactions to it. It has put phenotypes back in the center of evolutionary theory. Theoretical biology has produced surprising insights confirmed by quantitative tests.

Life history theory is helping evolution to become a scientific theory with the same general intellectual status as the great theories of physics.

NEUROETHOLOGY OF SEX- AND HOST-ATTRACTION IN MOTHS

John G. Hildebrand

ARL Division of Neurobiology, University of Arizona,
Tucson, USA

In moths and other insects, olfaction plays a major role in the control of important behaviors. Orientation and movement toward, and interactions with, receptive mating partners, appropriate sites for oviposition, sources of food, and hosts for parasitism typically involve olfactory signals that initiate, sustain, and guide the behaviors. Because of their prominence in the zoosphere, their economic and medical importance, and their usefulness as models for both behavioral and neurobiological research, insects have been extensively studied by investigators interested in mechanisms of olfactory control of behavior.

Insects respond to a variety of semiochemicals, including pheromones (chemical messengers within a species, such as sex attractants) and kairomones (chemical messengers between species and adaptively favorable to the recipient, such as attractants and stimulants for oviposition and feeding emitted by a host plant). Studies of insect responses to such biologically significant odors have shown that the quality and quantity of odorants in complex mixtures present in the environment are encoded in patterns of activity in multiple olfactory receptor cells (ORCs) in the antennae. These "messages" are decoded and integrated in the olfactory centers of the central nervous system (CNS), and it is there that olfactorily induced changes in the behavior or physiology of the insect are initiated.

Of paramount interest, both historically and currently, is the attraction of a mating partner by means of a chemical signal - the sex pheromone - released by a receptive individual of one sex and detected by conspecifics of the opposite sex. In moths, these chemical signals are the primary means by which females broadcast their sexual receptiveness over relatively long distances to conspecific males. The male moths respond to the sex-pheromonal stimulus with well-characterized mate-seeking behaviors involving patterned anemotactic flight, short-range orientation to the calling female, and mating.

Behaviorally relevant olfactory mechanisms have been probed in depth in several insect taxa, including cockroaches, honey bees, and fruit flies, but the most extensive explorations of the detection and processing of, and behavioral responses to, sex pheromones have been carried out in moths. Building upon earlier and recent work of others (e.g. References from 1 to 7) and paralleling the current research in many laboratories using different insect species, my coworkers and I study the olfactory system of the experimentally favorable giant sphinx moth *Manduca sexta*. We have investigated this model olfactory system extensively by means of anatomical, neurophysiological, biochemical, cytochemical, developmental, and cell-culture methods. This brief overview focuses on some of our findings and speculations about the functional organization and physiology of the olfactory system in *M. sexta*. More detailed reviews of this and other aspects of our work have been presented elsewhere⁸⁻¹², and our colleagues have made significant progress in studies of the pre-motor and motor aspects of the neuroethology of odor-guided

behavior as well as the behavior itself¹³⁻¹⁷.

A principal long-term goal of our research is to understand the neurobiological mechanisms through which information about a specific olfactory signals, the female's sex pheromone and the volatiles released by host-plants, are detected and integrated with inputs of other modalities in the brains of male and female moths, respectively, and how these messages ultimately initiate and control the characteristic behavioral responses of the moths. Pursuit of that goal promises to teach us much about how the brain processes chemosensory information and uses it to shape behavior. Our studies along this line to date have persuaded us that the male's olfactory system consists of two parallel sub-systems, one a sexually dimorphic "labeled-line" pathway specialized to detect and process information about the sex pheromone, and the other a more complex pathway that processes information about plant (and probably other environmental) odors encoded in "across-fiber" patterns of physiological activity. In this presentation our work on the male's olfactory system will be emphasized, but current studies of female moths will also be touched upon. Major features of the organization of the male moth's olfactory pathways are schematized in Fig. 1.

Olfactory primary afferents - Each of the 2 antennae of adult *Manduca* comprises 2 basal segments, which contain mechanosensory organs, and a long sexually dimorphic flagellum divided into ≥ 80 annuli (segment-like divisions) bearing numerous sensilla of several types, the great majority of which are olfactory. Antennal flagella of adult males and females have many ORCs (associated mainly with basiconic, coeloconic, and trichoid sensilla) that respond to plant volatiles.

Sexually dimorphic sensilla on male antennal flagella have been partly characterized in *Manduca*. Each male antenna has a total of $>3 \times 10^5$ ORCs associated with ca. 10^5 sensilla, of which ca. 40% are male-specific type-I trichoid (hair-like) sensilla^{18,21}. Type-I trichoid sensilla (100-600 μm long) are typical olfactory sensilla²², each innervated by 2 ORCs whose dendrites extend through the lumen of the fluid-filled hair to its tip. In most of these sensilla, one of the 2 male-specific ORCs is highly sensitive and specific to one of the 2 necessary and sufficient components (E10,Z12-hexadecadienal or component A) of the female's sex pheromone, while the second ORC is "tuned" to the second essential component (E10,E12,Z14-hexadecatrienal or component B)^{19,23,24}. These pheromone-specific ORCs thus have extremely narrow molecular receptive ranges, and each type collectively represents a narrowly tuned input channel that conveys information about the presence, concentration, and temporal patterning of one key pheromone component to the brain.

Antennal lobe and glomeruli in the adult - Ordinary glomeruli. The axons of antennal ORCs project, via the antennal nerve, strictly ipsilaterally and define 64 ± 1 large (50-100 μm in

MGC to higher olfactory centers³²⁻³⁹. PNs that respond preferentially to stimulation of the antenna with component A have arborizations restricted to the toroid, whereas PNs that respond selectively to stimulation with component B have arborizations confined to the cumulus³⁹. PNs that respond to both components A and B have arborizations in both cumulus and toroid. Thus these anatomically distinct MGC glomeruli are also functionally distinct with respect to their roles in processing of sex-pheromonal information and clearly exhibit narrow and specific molecular receptive ranges.

On the basis of their responses to antennal stimulation with pheromone components, uniglomerular MGC PNs have been classified in 2 broad categories: pheromone generalists and specialists^{34,35,37}. Pheromone generalists respond similarly to stimulation of either the component-A input channel or the component-B input channel and do not respond differently when the complete pheromone blend is presented to the antenna. In contrast, pheromone specialists can discriminate between antennal stimulation with component A and stimulation with component B. These PNs preserve information about individual key components of the species-specific blend. Our observations are consistent with behavioral studies and suggest that information about specific components of the blend, and not only the complete blend, is important to these animals. Another subset of pheromone-specialist PNs receives input from both component-A and component-B channels, but the physiological effects of the 2 inputs are opposite^{34,35,37}. Simultaneous antennal stimulation with both A and B elicits a mixed inhibitory and excitatory (-/+/-) response in these PNs. These PNs therefore can discriminate between the 2 inputs based upon how each affects spiking activity. Thus different output channels from the MGC convey infor-

mation about different aspects of the pheromonal stimulus. Such a study of odotopic organization of olfactory glomeruli depends on our ability to identify discrete glomeruli from animal to animal.

Higher pathways - After synaptic processing in the AL, information about odors is relayed to higher centers in the protocerebrum by way of the axons of AL PNs. We have begun to explore the physiological and morphological properties of neurons in the protocerebrum that respond to stimulation of the antennae with sex pheromone, host-plant odors, or their components^{40,41}. We find that many odor-responsive protocerebral neurons have arborizations in the lateral accessory lobe (LAL), which appears to be important for the processing of olfactory information. Different types of higher-order neurons link the 2 LALs to each other, to the ipsilateral superior protocerebrum, to the lateral protocerebrum (where axons of AL PNs terminate), and to the thoracic ganglia³²⁻³⁴. Thus, the LAL is interposed in the pathway of olfactory information flow from the AL through the lateral protocerebrum to descending neurons. Certain neurons associated with the LALs give dramatic, mixture-specific, long-lasting excitatory responses of a character not observed at the level of the AL. We have hypothesized that such long-lasting responses may prove to be important for generation of behavior that depends on specific mixtures of odorants

Acknowledgments - The author is grateful to his many coworkers and collaborators who have contributed to the line of research covered in this brief review. This research has been supported by a series of grants from NIH and NSF, and recently by NIH grants AI-23253, DC-00348, NS-28495, and DC-02751.

PROBLEMS AND TRENDS OF AGRICULTURAL ENTOMOLOGY AT THE END OF THE 2ND MILLENNIUM

Manes Wysoki

Dept. of Entomology Institute of Plant Protection,
Volcani Center, Bet Dagan, Israel

Insect and acari are the main targets in agricultural entomology because they are pests of agricultural crops and vectors of transferable diseases (human, animals and plants). Insects are also beneficials (predators and parasitoids of pests); they play an important role in the food chain as a food; they are producers of food (honey) and other products producers (silk, wax), and extremely important as pollinators. Agriculture entomology of the end of the second millennium must face many problems which are connected with food production and deal with insects as competitors taking a large part of our yields.

Entomology is not an isolated science dealing only with all aspects regarding insects. It is strongly connected to other fields of our life, like demography, environment, transport, trade, tourism, food production, public health and others. The problems connected with entomology in the second millennium derived directly from overall human life and development in this period; some of them were created by human beings, others are created by insects themselves as a natural way of self defense. Problems that we created derived from our customs, behavior, economics, politics, effort to rule them according to our essential needs of providing food and fiber, and from health trends. Therefore, the main problems are pests and pest control for prevention of food losses and maximizing food supply, implementation of different control methods and their impact on environment and public health, especially extensive use of chemicals and development of new insecticides compatible with the environment, outbreak of indigenous pests, and introduction of new exotic pests to new areas.

Since human population will continue to grow, it is important to eliminate, as much as possible, factors limiting food production. Malnutrition is still the main problem in developing countries suffering from a limited food supply and from growing problems with pests and their control. According to the Food and Agriculture Organization (FAO) of the United Nations, 780 million people are suffering from hunger in developing countries only. Children are the majority with consistent undernourishment.

The growing demand for food depends on effective and reliable pest control, and chemical control is a very important part of it. Some environmentalists want to ban or at least to reduce the use of pesticides because of their influence on the environment, especially because of the uptake by crops and later on to be subsequently incorporated in the food chain, and because of contaminating soil, water, and having a detrimental influence on the ecosystem. On the other hand, people involved in agriculture claim that it is necessary to use those chemicals for getting a reasonable amount of yield and to reduce as much pest induced losses as possible. The most famous organochlorine insecticide DDT (Dichlorodiphenyltrichloroethane) was synthesized in 1873. In agriculture it was extremely effective against a number of pests devastating maize and potatoes. But the disadvantages

of its use soon became apparent, because it accumulates in fat body of mammals, it was responsible for the death of fish and birds.

The public, governments, health authorities, and environmental organizations are concerned about the tremendous use of insecticides, because of the apparent impact on health, environment and especially by contamination residues in water and surroundings, as well as the problems with applications when the toxic material is used in fields. Some insecticides have a chronic toxic effect on reproduction; they have mutagenic and oncogenic effects and cause long term damage to the nervous and immune system (Culliney et al, 1992).

In many countries the concern about health and environmental hazards led not only to banning some dangerous pesticides, but to serious cuts of all agriculture pesticides by legislation mandating the reduction of 50% or more of the total use by the year 2000. The three leading countries are Sweden, Denmark and the Netherlands. Two bills relating to pesticide use reduction were introduced to Congress in the USA in 1994, which included establishing and implementing pesticide use reduction (in selected ecosystems) and pursuing alternatives to chemical uses (Matteson, 1995). The main reasons for search and implementation of alternatives to pesticides as pest control methods are: (1) residual effect in agricultural products and the threat to the public health, (2) high cost of pesticides when the pest control rely entirely on expensive insecticides, (3) nonselectivity of some pesticides, (4) developing resistance in target pests, (5) effect on nontarget organisms, (6) outbreak of secondary pests, (7) high costs of developing new insecticides and obstacles with receiving a permit, (8) dangerous way of production, transport and application, (9) impact on environment (water, soil, air), (10) broad knowledge of pesticide science, high awareness and education of people to problems caused by insecticides, (11) high prices for non treated agricultural products, (12) antipesticides legislation and banning of some most effective insecticides, (13) political pressure (green peace movement, popular slogans in election companies) and finally, (14) the psychological impact. Problems connected with use of insecticides were the main forces to change the strategy of pest control and to implement Biological Control (BC), Integrated Pest Management (IPM) and other alternative, environmentally accepted methods, when they are economically motivated. The new products that expect to discharge or reduce chemical control are: bacterial insecticides, viruses, protozoan, nematodes, fungal insecticides, natural occurring pesticides (antibiotics and fermentation products), botanical pesticides (of plant origin), Insect Growth Regulators and Juvenile Hormones Analogs, semiochemicals (pheromones) and genetic engineering products (engineered baculoviruses and bacteria, transgenic plants producing toxins, genetically improved natural enemies).

In our millennium chemical control is still the basic method

for pest control, but because of all the mentioned problems the other alternatives are of great importance. The most important are Biological Control (BC) and Integrated Pest Management (IPM), although only about 5% of all pest problems are alternated by those methods. BC, according to Van Driesche and Bellows (1996) "is the use of parasitoid, predator, pathogen, antagonist, or competitor population to suppress a pest population, making it less abundant and thus less damaging than it would otherwise be. In the second millennium hundreds of examples of successful biological control are given by DeBach (1970), Huffaker (1971), Clausen (1978), Greathead and Greathead (1992). More than 220 examples of successful biological control involving 110 species of pests in 60 countries are given by Wilson (1970), more than 540 target insect pests in more than 1,200 introductions are included in biocontrol programs described by Greathead and Greathead (1992). From 860 releases in which 2,741 pest species were involved, 216 effective control cases with 393 parasitoid species were described (Van Driesche and Bellows, 1996).

BC however is not without problems. After a hundred years since the first successful use of biological control, fundamental questions such as how often, how many, and how and where the natural enemies should be released are still not known. In all cases the experimental design is critical and will require considerable time, effort and expense. These factors are probably the underlying causes of the lack of the research in this area (biological control) (Parella et al, 1992).

Several failures of unsuccessful introductions are given by many authors (Messenger, 1971; Hokkanen, 1985; Stiling, 1990). Fourteen different reasons why released natural enemies were deemed to fail (Stiling, 1993) are: (1) climate, (2) weather, (3) lack of synchronization, (4) wrong strain, (5) different habitat preferences, (6) host or prey refuge, (7) competition, (8) predation, (9) parasitism or hyperparasitism, (10) lack of alternative hosts, (11) lack of adult food, (12) low rate of increase, (13) too few releases, and (14) migration.

In the analysis of 148 cases of failure of introduction, the most common reasons were climate (24.3%), lack of alternative host (14.9%), and wrong strain. The other reasons did not reach 10%. Between them were the lack of synchronization (9.5%), hyperparasitism, parasitism (8.1%) and predation (6.8%) (Stiling, 1993). The mortality of natural enemies from sprays is caused by direct influence or by residual effect; other effect of insecticides are reduced fertility, shorter longevity, lack of hosts, repellency, low reproduction rates. Only few insecticides are considered to be harmless to natural enemies: pirimicarb, fenbutanine oxide, diflubenzuron, some plant derived insecticides, avermectin, narrow range oils, and systemic demeton and alocy-carb (Van Driesche and Bellows, 1996).

One of the important trends in second millennium is recognition of importance of Integrated Pest Management (IPM). Although IPM is described as an interdisciplinary approach to the solution of agricultural problems (Hoy and Herzog, 1985), it is based generally on biological control, carefully pest monitoring, developing thresholds followed by known control methods such as chemicals, which are used if it is necessary to avoid economic crop losses. The use of chemicals must be reduced to a necessary minimum, and include as much as possible, selective chemicals. Agrotechnical methods that are compatible with the environment are also a part of IPM and are incorporated in many ways. The implementation of these methods must be followed by excellent extension service, farmers education and of cooperation with responsible, in charge authorities.

As one of the solutions to replace the expensive and some-

times dangerous chemical control, was the attempt to use pathogens and nematodes, to find proper control agent and with all restrictions to find a practical use for them. This area has become an important and rapidly growing area of science. Spectacular success has already been achieved by tide cooperation of entomologists with virologists, microbiologists, parasitologists and scientists from other related fields. Insect pathogens are environmentally safe, selective, some of them once introduced provide sufficient pest control for an extended period, some of them have even competitive prices with chemical insecticides. "Successful commercial development of pathogens augmentative biological control involves: agent selection (to obtain the best species and strains for the target pest); development of cost-effective methods for mass rearing; effective methods for storage and shipping of the agent; creation of formulation to protect and deliver the agent to the target pest's location; field testing of the product's efficacy and method for its application; economic factors affecting product development and markets; and demonstration of product to man and the environment" (Van Driesche and Bellows, 1996). The following groups are used: viruses, bacteria, fungi, protozoan, and nematodes. But those products are as well not free from general problems of chemical insecticides and recently there are reports on resistance developed in insect against some granulosis virus and *Bacillus thuringiensis*.

Insect Growth Regulators were accidentally discovered in 1970 by Philip-Duphar scientists in The Netherlands (Van Daalen et al, 1972; Wellinga et al, 1972 a,b). They are divided into two major groups: (1) Chitin Synthesis Inhibitors (CSI's) and (2) Juvenile Hormone Analogs (JHA's) (Miyamoto et al, 1993). Those CSI's are developing molt disruption of lepidopterous larvae, however they may have adverse effects on beneficial insects. Additionally to larvicidal effect, in some cases they show ovicidal and sterilizing activities, suppress fecundity and demonstrate contact toxicity (Arambourg et al, 1977; Asher and Nemny, 1974). Juvenile Hormone Analogs interfere with insect metamorphic changes.

The different groups of those insecticides are now incorporated in many programs of IPM, but not surprisingly they are not free from the problems of chemical insecticides. Resistance is found more and more among them. Although the discovery of CSI's led to extensive research in the field of insect cuticle biochemistry and chitin synthesis, hundreds of chemicals were screened and found to be potent inhibitors; many more studies are needed to evaluate those products, especially with regard to environmental impact. Without intensive studies of resistance and establishing IPM strategies, those insecticides will suffer from all problems of chemical commercial insecticides.

The use of semiochemicals was a significant development in agricultural entomology. Semiochemicals are compounds that are emitted or displayed by one organism and that affects the behavior of another organism (Rigway et al, 1990). Chemical communication is important in life cycles of many insects, especially for location and mates and food. They are widely incorporated in many IPM programs and used in two ways: by monitoring pest population and by preventing insect caused damage. The most common semiochemicals are pheromones, followed by antifeedants and repellent compounds (Bjostad et al, 1993). The principal value of monitoring is to reduce the amount of insecticides but at the same time maintain acceptable insect control. Early detection of pests, the presence or absence, has a crucial role in decision making regarding the insecticide application.

The most common use of semiochemicals is in behavior disruption, on which the technique of the placement of many

sources of pheromones placed in the field caused "confusion" of the males. The males are unable to locate the female mate and the large amount of synthetic pheromones in the field confuse them. Another technique developed is mass trapping where the male population is significantly reduced and the unmated population of females fail to produce offspring. Another trend in semiochemical research and development is evaluation of the influence on natural enemies. Some of the parasitoid wasps are attracted to pheromones of their host and increase in such a way the search ability of the parasitoid to find the target pest.

Important steps in development of pheromone research include practical use for direct control of pest populations and for integrated control in IPM programs together with agricultural methods, biological control agents, and insecticide, and such interaction can maximize the advantages of all of them. The advantages of using pheromones are: their selectivity, they are specific for each pest species, they are degradable - therefore there is no residual effect, non toxic, do not interfere with biological equilibrium by absence influence on beneficial insects, and the high cost of production is balanced by the small amount usually used. The research that will provide any understanding of the communication system, will be a result of close cooperation of entomologist, biochemist, physiologist, behaviorist, molecular biologist, and will lead to new, more sophisticated pest control and plant protection.

To find insecticides more compatible with IPM and environmental requirements, in the last three decades interest was revived for insecticides originating from plants. Plants are a rich source of phytochemicals and until now about 10,000 such chemicals have been isolated; the estimated number is closer to 500,000. Natural pyrethrins, nicotine and rotenone have been in use for a long time. The most prominent are now the Neem products from leaves and seeds of Neem trees, called Indian lilac, *Azadirachta indica* (= *Melia azadirachta*) or from related species. Despite selectivity, there are about 200 species controlled by Neem products and, until recently, there is no reported case of resistance.

In 1976 in a culture of *Streptomyces avermitilis* (Burg), collected in soil samples in Japan, scientists discovered a complex of eight closely related natural products which were insecticidal in nature and named avermectins. They have insecticidal activity against many important insect pests and are more effective against many mite species, but resistance was already found to this product in mites (Hoy and Conley, 1987). These products are candidates "for further development representing linkage of many scientific disciplines spanning natural products, chemistry, organic, synthetic and biochemistry with the applied investigators in agriculture, human and animal health" (Bowers, 1989).

The most recent development in plant protection connected with entomological research and in the beginning of implementation is genetic engineering using molecular methods. To improve the performance of *Bt* and viruses different methods are used. To overcome the limited host range of *Bt* several methods were employed to combine different strains in one product. Recently new genetic engineering methods are used to increase the ability of killing pests by viruses by inserting specific genes into baculoviral genome. Baculoviruses are used as an excellent expression vectors for basic and applied research, because they have easily modified genomes, strong promoters to drive foreign gene expression and markers for the detection of foreign gene insertion. They are widely used as vectors for foreign gene expression in insect cells by replacement of the polyhedron gene with a foreign gene (Maeda and Hammock, 1993).

Peptides and polypeptides, ectosteroids and juvenile hormone

analogues of insect and noninsect origin can exhibit insecticidal effects without affecting other organisms (including vertebrates). The following are the categories of candidate genes for construction of recombinant baculoviruses for insect pest control: enzymes and enzyme inhibitors, neuropeptides, venom toxins (of scorpion, mites, spiders and insect paralytic wasp) and *Bt* toxins (Maeda and Hammock, 1993).

Other genetically engineered products include plants producing insecticide to repel or kill phytophagous insects. They can be genetically manipulated and produce a higher level of natural insecticide (introduction of *Bt* toxin). Generally, the plants in which genetic material from other species was inserted by biotechnology are called transgenic plants and were developed for major crops of the world (Jenkins, 1993). This genetic engineering technology will have an important impact on the pest management strategies in the major crops (potatoes, corn, cotton, etc.) and will be implemented not only on an economical basis, but with their compatibility with other practices as well, like biological or IPM control methods. Those transgenic plants are produced on a commercial scale and will probably suffer from appearance of resistance in the pest attacking those plants. Recently after more than 20 years of using commercial *Bt* preparations, resistance to *Bt* is reported not only in laboratory experiments but in the field as well (Tabashnik, 1994).

The next step in genetic engineering is genetically improved strains of beneficial insect, not only by selection but by transferring to them pesticide resistant genes by recombinant DNA techniques. Recombinant DNA (rDNA) techniques to develop transgenic beneficial arthropods have been developed recently and are useful when the natural enemy is effective except for some limiting factors and the limiting trait primary is influenced by a single major gene (Hoy, 1993). Those new techniques offer new opportunities for pest management but created as well many problems connected with many still unknown results. The greater the genetic novelty, the greater are the possibilities for surprising results (Williamson, 1992). Therefore, for the first release it may be proper to choose a relatively risk-free beneficial. Such a candidate becomes a predatory phytoseiid mite *Metaseiulus occidentalis* a transgenic strain developed by inserting gene for organophosphorous (OP) resistance, and in December 1995, Marjorie A. Hoy (University of Florida) asked USDA for permission for first outdoor releases of this altered beneficial, and in March 1996 the first experiments were performed. It may take 5-10 years of evaluating small-scale releases before permanent releases will be permitted.

The high trade movement of all kinds of merchandise, lack of effective quarantines, the boom of tourism and other kinds of people movement (like emigration, family reunions, transfers, search for work), and related exchange of products of different agricultural origin, unintended introduction or intended smuggling of plants and plant origin products, favor the spread of every exotic pest, which will become a pandemic pest and will not be any more limited to certain areas of their origin. Samples include introduced lately insects that become world-wide pests, such as the most famous western flower thrips, *Frankliniella occidentalis* and the latest citrus pest, the citrus leafminer, *Phyllocnistis citrella*. A new threat for the citrus industry arrived in Florida in 1995, with the detection of a tristeza virus carrier, the brown citrus aphid, *Toxoptera citricida*. It is expected that this aphid will infest most of the citrus growing area of Florida at the end of 1996.

It is only a matter of time, suitable environment including proper host, adaptation and we have a new pest in a new part of the world. Only in Florida is it estimated that approximately 12

exotic species are introduced annually (Capinera et al, 1994). From a list of 343 scale insects recorded in Italy from the 1980s until 1993, 44 species were introduced. Those species are native *inter alia*, to Australia, Eastern Asia, China, Central America, Northern America and South Africa (Longo et al, 1995). Taking into consideration only Coccinac, in The Netherlands during 1950-1994, 143 species were intercepted (Jansen, 1995).

No doubt that the best way to deal with introduced new pests is prevention, but it is impossible to seal hermetically the borders and the in gates of entrance. However, it is possible to reduce the invasion of exotic pests by enforcement of effective quarantine regulations. This will be provided by more manpower on the border stations, and more effective inspection of agricultural commodities and through education, proper explanation of the danger of such introductions and proper information on consequences of uncontrolled plant material movement. Once introduced, pests are likely to establish and can be controlled by eradication or by introducing as soon as possible natural enemies from the country of pest origin (biological control). Eradication is expensive, sometimes ineffective and disrupts the biological balance between exotic natural enemies of other pests in the same environment and as a result not successful. When natural enemies are introduced, it must be made as soon as possible to avoid the spread and establishment of the pest in large areas. In some countries, governments instead support the import of natural enemies by giving immediately financial support and import permits, sometimes delay by cumbersome restrictions, natural enemy introduction, mass breeding and field releases. The concern about introduction of natural enemies is sometimes irrational and the danger to endemic fauna is overestimated.

The next vital problem at the end of the present millennium is education of a new generation of entomologists. The progress in developing reliable plant protection methods which will include all the above described methods, in different fields of entomology, will depend on funds that governments, private sectors, scientific funds and growers' associations can provide to scientists and extension services. This will support the basic and applied research, developing new, more expensive technologies and attract a young generation of scientists dedicated to different fields of entomology. In entomology, one of the problems was lack of essential support for research in systematics. Oliver (1988) wrote that a purpose of his article is "to alert the entire scientific community to the crisis in systematics in all its manifestations, including identification service and evolutionary history, and scientists from other disciplines and administrators must understand the practical and immediate role that systematics plays in many areas." Recently, the authorities appear to understand this warning, and the pressure from scientists that recognize the gap in this field, that created problems with identification of insects and especially pests, lead to recruitment of more young entomologists being employed in this field.

Extension service serves as a messenger from research to producers. The traditional extension research model has been historically defined by five stages: (1) extension specialist listening to producers, (2) reporting problems to researchers, (3) helping solve the problem, (4) conveying the solutions back to producers, and (5) implementing the solutions (Gray and Edwards, 1993). Additionally, the extension service must provide all the available information regarding specific pest problems. Since more and more people involved in agricultural production are highly educated, and the modern agriculture requires basic skills as well, the extension services are more important and expected to be more sophisticated. From an extension service officer, who provided all needed information, we went up to a new era of

extension when the well educated officer must not only supply the necessary information and give answers for many questions to avoid or reduce the level of economic injury, but must also adapt this information to local conditions (like climate, soil, surroundings) taking into consideration different pest appearance and their natural enemies. In addition, he must be the messenger who delivers all the new information achieved by scientists to practical, large-scale use. So much depends on extension services if the tremendous available knowledge supplied by research will find its way to the field, and the greatest challenge will be to go from high technologies to extensive practical implementations.

The new generation of educated producers and availability of needed information through the electronic media, may be probably less dependant on extension services. Therefore there must be a strong partnership between scientists, extension service and producers.

There are now a wide range of databases and a part of them are relevant to plant protection and pest management. Hamilton (1991) listed 14 such databases, connected with pest management, the largest ones are BIOSIS PREVIEW, CAB ABSTRACTS, AGRICOLA, AGRIS, CSA LIFE SCIENCE COLLECTION and some of them highly specialized in this field, PEST MANAGEMENT RESEARCH SYSTEM, PEST-DOC. They are of different sizes ranging from 750 records to 6,156,000 records (BIOSIS PREVIEW) with annual growth rate of 360,000. The time span started of some of them from 1968 or even less and this created problems specially for young scientists that the previous data must be still gathered by old methods.

VanDyk (1995) provides us with information regarding the use of the Internet as entomologists. The Internet provides useful tools including e-mail (electronic mail), mailing lists, Uniset, Gopher and World-Wide Web. E-mail is the most useful tool which allows rapid communication with anyone who has access and an account. It is extremely fast, it is sent, sorted and received by computer, without paper or envelope, and allowed to get an immediate answer. Electronic mailing lists are a forum for discussion and announcements to everyone on the list. Uniset and Gopher are other programs providing communication and exchange of information. The World-Wide Web is the most exciting way to exchange information and based on text with links and links consist of words that will lead you to information related to links. Information is not limited to text but pictures, sound and movies are provided.

In the future many (if not all) journals will be published electronically. The first entomological journal is the Florida Entomologist, available on Internet since vol. 77 of 1994.

The end of the second millennium was characterized by tremendous cooperation of scientists from many disciplines of basic and applied entomology. By using new developed technologies, such as tissue culture, *in vitro* culture of pathogens, developing transparent and scanning electron microscopes, chemical and biochemical methods for detection of new pesticides, discovery of the mode of action, use of irradiation techniques, employee semiochemicals and disruption of physiological processes, genetic engineering and genetic improvement etc. will cause an "emergence of cross disciplinary insect scientists motivated by both fundamental and applied perspectives and fueled by the national (and international) need for selective, environmentally pacific methods of pest and disease control promises to enhance the stature and visibility of our science of entomology for the next hundred years" (Bowers, 1989).

With all this tremendous progress in the mentioned technologies and new, more and more sophisticated methods, will not be

a substitute for human brain, eyes, intelligence, ability of observation and possibility of drawing right conclusions. Of many subjects that I tried to cover in this paper, probably there are a lot more important developments in agriculture entomology that are

in the meantime, small discoveries, but they are bricks in the hugh building of plant protection research and they will find their expression and will influence the future research and practical applications.

ROLE OF SALIVA IN BLOOD FEEDING BY ARTHROPODS: DIVERSITY AND REDUNDANCY

José M.C. Ribeiro

National Institutes of Health, Laboratory of Parasitic Diseases,
Bethesda, USA

It is very well known to entomologists that insects represent a very large and diverse group of animals. Indeed the sheer number of insect species supersedes that of all other land animals and plants taken together. Additionally, insects have evolved and radiated in a way to exploit all forms of food and shelter, in many cases many different species providing many different solutions to the same environmental, physiological or biochemical problem. The diversity of solutions insects found to their common life problems thus provides the biologist with a rich source to understand life in its many facets.

Among the many different food sources insects evolved to exploit, blood from vertebrate animals, in particular, became the sole source of food for many insects, or the source of food for the adult female insect in her search for a protein rich meal to provide for egg development. Thus, at least 12 insect families evolved independently to hematophagy, consisting of 402 genera and 13,795 species. If we lump together also the tick cousins, which medical entomologists adopted in their practical wisdom, we add another 800 species of blood sucking arthropods¹⁹. If one realizes that all land vertebrates from turtles to mammals have a total of 18,100 species⁹, there exists about one blood sucker arthropod species for each land vertebrate species. Considering that mammals evolved in the past 60 million years, and that even insects within the same family can be more distant than 100 million years, than it is apparent that a large number of species have undergone convergent evolution to exploit this unique food source.

Among the unique problems insects and ticks had to adapt themselves were: (1) How to find a host? (2) How to take blood out? (3) How to digest and cope nutritionally with this unique meal? Many of the interesting research going on vector biochemistry and physiology now addresses these questions. This short review will address the problem blood sucking arthropods face when taking blood from their hosts.

The problems associated with stealing blood from vertebrates - When attempting to take a blood meal, insects and ticks face problems of both mechanical and physiological nature. The mechanical aspects of blood feeding were solved in two basic types, either by piercing and sucking mouthparts (leading mostly to feeding from within vessels), or with cutting mouthparts, where feeding is done from a hemorrhagic pool. In any case, successful blood suckers need to keep the blood flowing during the feeding process and against this goal there occurs the vertebrate hemostatic system, which prevents blood flow from injured vessels by a very redundant and sophisticated physiological system consisting of platelet aggregation, vasoconstriction and blood coagulation. Insects and ticks have thus evolved a very amazing array of pharmacological antihemostatic substances which makes them true pharmacologists every time they feed, if by pharmacologist we understand as someone that makes a liv-

ing by changing someone's else physiology¹⁹.

In the remaining of this paper the host hemostasis will be reviewed, as well as the several mechanism hematophagous arthropods found to disarm their host's hemostasis. Emphasis will be given to show that when common things shows up, they are actually different.

The vertebrate hemostasis - To have in perspective the complexity of the task of counteracting the vertebrate hemostatic system, it is useful to realize that blood clotting, platelet aggregation and vasoconstriction mechanisms are redundant themselves: blood coagulation occurs through two pathways, the intrinsic and the extrinsic, both of which, through independent mechanisms, activate Factor X to Factor Xa. The intrinsic pathway is triggered by the exposure of blood to subendothelial components, such as collagen. This can activate plasma Factor XII, leading to a number of reactions ultimately activating Factor X. The extrinsic pathway is triggered by the release of tissue thromboplastin from injured cells, which also ultimately leads to activation of Factor X. Factor Xa converts prothrombin to thrombin, the enzyme that produces fibrin from fibrinogen. Platelets can aggregate from at least 3 pathways, induced by ADP, thrombin, or collagen (which triggers platelet synthesis of the eicosanoid thromboxane A₂). Although each of these mediators may potentiate the other's action, each individually can give a full aggregatory response if the proper dose is present. Finally, vasoconstriction of venules and arterioles can be promoted by serotonin and thromboxane A₂ released by aggregating platelets, and by other mediators released by local neural reflex, or other inflammatory cells, such as neutrophils and mast cells. Accordingly, blood sucking arthropods have evolved an array of different anticoagulants, anti-platelet substances, and vasodilators^{12,18,19}.

Anticoagulants - Since the beginning of the century it is known that saliva of blood sucking arthropods contain anticoagulant properties⁷. Indeed, at that time it was believed that only coagulation accounted for hemostasis, despite the observations of Bizzozero at the end of the last century, implicating platelets in hemostasis³. In the last decade a number of anticoagulants have been characterized molecularly, indicating a vast array of different molecules acting against different factors of blood coagulation. It is interesting that there is a concentration of anticoagulant factors against Factor Xa and thrombin, the two final steps of the coagulation cascade. Unique polypeptides affecting the stability of the Xase complex have being discovered in *Rhodnius* and *Cimex*²³, Valenzuela and Ribeiro, in press). Such anticoagulants do not act by antagonizing enzymes, but rather disrupt the complex formed by phospholipids, Ca²⁺, Factor VIII and Factor IXa, this complex being responsible for activating Factor X to Xa. It is also interesting that blackflies, which feed from hemorrhagic pools and thus face a double threat from coag-

ulation, have developed a cocktail of 3 different anticoagulants, an anti-Xa, an anti-thrombin and an anti-Factor VII^{1,2,11}. Ticks, who also feed from hemorrhagic pools, have developed anti-tissue multiple anticoagulant cocktails¹⁰, and it may be possible that such mixtures of anticoagulants will also be found in other hemorrhagic pool feeders.

Anti platelets - Platelet aggregation represents the most immediate reaction against blood loss, indeed being sufficient to arrest blood flow from small vessels in the absence of a functional blood clotting system¹⁵. Not surprisingly, most hematophagous arthropods so far studied have abundant salivary anti-platelet activities. Among the anti-platelet compounds, the enzyme activity ATP-diphosphohydrolase (apyrase) has been a common finding. The salivary apyrase of the mosquito *Aedes aegypti* has been purified and cloned, and shown to belong to the family of 5'-nucleotidases⁶. Other apyrases from hemiptera are being cloned (Champagne, unpublished), and appear to have originated from an altogether different family of proteins. A picture is emerging indicating that even the common finding of salivary apyrase in blood sucking arthropods derives from convergent evolution.

In addition to apyrase, ticks have prostaglandins that have antiplatelet activity, and more recently a variety of unrelated peptides that target different sites in the process of platelet aggregation were discovered in deer flies and triatomine bugs¹⁹. The triatomine bug *Triatoma pallidipennis* contains at least two homologous proteins with sequence similarity to apolipoprotein D, named pallidipin¹⁶ and triabin¹⁷, which inhibit collagen induced platelet aggregation and thrombin, respectively. This shows how a possible scenario of gene duplication may have lead to different functions in homologous molecules.

Vasodilators - Salivary vasodilators are widely found in blood sucking arthropods, and these are thought to help feeding by counteracting the vasoconstrictors released by aggregating platelets, or to increase the skin blood flow and thus the supply of food to the feeding insect. Perhaps because of the diversity in the species background from which blood feeding evolved, a corresponding diversity in vasodilators exists. Thus, prostaglandins, peptides, nitrovasodilators and enzymes destroying vasoconstrictor amines have been found in the saliva or salivary gland homogenates of blood sucking arthropods.

An interesting finding in blood sucking hemiptera (*Rhodnius* and *Cimex*) was a salivary nitrovasodilator that consists of the gaseous and reactive substance nitric oxide (NO) associated with a myoglobin-like molecule that was named nitrophorin^{4,20,25}.

Rhodnius prolixus has 4 such nitrophorins, all now cloned (Champagne, unpublished), and *Cimex lectularius* has one such molecule, also cloned (Valenzuela, unpublished). *Cimex* and *Rhodnius* nitrophorins are completely unrelated molecules, and are thus products of convergent evolution serving the same purpose, that of carrying the vasodilatory NO gas to our skin, so the bugs can feed faster.

The sand fly *Lutzomyia longipalpis* contains a novel vasodilatory peptide that has been characterized as the most potent and persistent vasodilator known. This peptide of approximate MW of 7,000d, is now sequenced and synthesized^{13,14}. The vasodilator may be responsible for the immunosuppressive effect of sandfly saliva leading to enhancement of *Leishmania* infection²⁴. Interestingly, Warburg and cols²⁶ noticed that there is a very large variation, both in amount of vasodilator and in peptide sequence, among different geographical isolates of the fly *Lutzomyia longipalpis*. These differences are also correlated with differences in the epidemiology of clinical manifestations of visceral leishmaniasis in Central and South America.

Recently the salivary vasodilators of *Aedes aegypti* have been sequenced and shown to be octapeptides belonging to the family of tachykinins⁵. Similar vasodilator was found in *Ae. triseriatus*²², but *Anopheles* mosquitoes possess a peroxidase with activity against vasoconstrictor amines²¹, and do not possess tachykinins. The totally different process these two mosquitoes found to increase skin blood flow is perhaps not surprising if we take in consideration that Culicines and Anophelines have separated 120-150 million years ago and mammals have irradiated about 60 million years ago.

Currently, vasodilators from black flies have been purified⁸ and cloned (Cupp, unpublished), and represent a totally new family of vasodilators (Marydillan).

Conclusion - With over 14,000 species of blood sucking arthropods in over 400 genera, the complexity of the hemostatic vertebrate system lead blood sucking arthropods to evolve a not less array of pharmacologically active substances that we are now only beginning to comprehend. Even when similar things appear, as in the case of the apyrases, or nitrophorins, they may be non homologous and thus a product of convergent evolution. When they are homologous, as in the case of the sand fly vasodilator Maxidilan, a large diversity may exist that represents a naturally occurring site-direct mutagenesis-type of work that may be useful for structure/function studies. It will take some time to learn what these blood suckers have to teach us, but it will be an interesting and meaningful endeavor.

PATTERN FORMATION IN INSECT EMBRYOGENESIS: THE EVOLUTION OF CONCEPTS AND MECHANISMS

Klaus Sander

Institut f. Biologie I (Zoologie),
Freiburg i.Br., Germany

This lecture, which is to acknowledge an award*, will review two interrelated topics. Both concern the mechanisms of embryonic pattern formation, defined as the manifold processes that transform the simple spatial structure of the egg cell into the highly complex three-dimensional organization of the future body. This transformation, repeated stereotypically in each new generation, is one of the most characteristic properties of living beings. Our insights into the mechanisms that accomplish it has dramatically increased in recent years, primarily by research on insect embryogenesis.

Of the two evolutions addressed in the title, the first is part of the history of biology. It concerns the major conceptual steps by which insect embryologists have reached their present knowledge and insights. The second (treated rather briefly) concerns a basic aspect of biological evolution, namely the progressive modification of embryonic patterning mechanisms while crucial molecules involved were strongly conserved. Two sets of such molecules have recently provoked novel and far-reaching conclusions concerning the course of metazoan evolution at large, and these will be briefly outlined as well.

Before embarking on either kind of evolution, the diversity of early embryonic patterning in insects needs to be outlined (Krause, 1939; see Sander, 1976)**. In “short germ” development, the as yet unsegmented embryonic rudiment (or “germ anlage”) is short by comparison with the egg cell, and gives rise to the segmented germ band by “budding”, i.e. by generating the body segments sequentially from anterior to posterior. In “long germ” development, a store of organelles etc. provided by the nurse cells permits the rapid development of a large germ anlage (often as long as the egg itself) which then subdivides more or less simultaneously into the full number of segments. In many insect groups, traits of both these segmentation modes are combined: the major part of the germ anlage yields some anterior segments by (nearly) simultaneous subdivision whereas the remaining segments are added sequentially. This is the “semi-long” or “intermediate” type of patterning. Besides segmentation as such, its relative timing with reference to gastrulation may serve to define the three (or more?) insect germ types (Patel). With respect to biological evolution, long germ development no doubt is a derived mode while opinions differ on the mode ancestral for insects (short or intermediate germ?).

As for mechanisms patterning animal embryos, the modern view combines traits of two philosophical concepts, namely epigenesis and preformation. These ancient terms were revived early in our century (mainly by work on sea urchin embryogenesis), but with some change of meaning: preformation prevails in the genes, but their linear information is transposed into the complex three-dimensional structure of the body by epigenesis,

now defined as the intricate interplay of relevant genes with each other and with some simple spatial cues conferred on the egg cytoplasm during oogenesis.

Insect development has influenced concepts of embryonic patterning since the beginnings of mechanistic biology in the 18th century. The first observations, however, seemed to support a concept which denies any *de novo* patterning, namely embryonic preformation. Noting that newly born viviparous aphids can encase a complete larval body representing the next generation, Charles Bonnet claimed the “*préexistence en miniature*” of the offspring within the mother, and postulated the bodily “*emboîtement*” (encasement) of all future generations.

However, progress in microscopy revealed that the egg (or spermatozoon for that matter) does not contain the body *en miniature* to begin with, and the concept of *emboîtement* became discredited because of the minuscule dimensions implied for the preformed bodies of distant generations. The conceptually simplest way for bypassing these obstacles while maintaining mechanistic causality was “neo-preformation”. It replaced the various parts of the (no longer pre-existent) body with a preformed pattern of invisible “determinants” in the egg, each determinant directing the development of the respective body part in its place.

Despite much evidence to the contrary (e.g. in sea urchin embryogenesis), variants of this static “mosaic egg” concept have lingered on in some minds well into our century - and nowhere longer than among *Drosophila* researchers (e.g. Waddington, 1956) where they ultimately took the guise of pre-localized determinants for individual imaginal discs. This idea may have been encouraged by Ernst Hadorn’s pioneering work on imaginal disc determination (see Garen, 1992) and by the demonstration of prelocalized germ line determinants (see Sander, 1984) which lent themselves as a model for putative determinants in other parts of the egg cell. However, most proponents of this illicit extrapolation knew that it would not solve the problem of *de novo* generation of spatial complexity, but merely shift the burden from embryogenesis to oogenesis which accordingly - and vainly - began to be screened for appropriate mutants (see Garen, 1992).

Factual evidence against the putative mosaic of ooplasmic determinants was first obtained for intermediate and short germ development, mainly by duplications and complete twinning that had been induced in these forms experimentally (see Seidel, 1936). Meanwhile, a more dynamical alternative to the mosaic egg concept had been established for some other animal groups. Here embryonic patterning was ascribed to inductive signals (of unknown constitution) spreading from a morphogenetic centre - the “centre of first differentiation” in the sea urchin embryo or

* The “Distinguished Award in Insect Morphology and Embryology”, sponsored by the International Journal of Insect Morphology and Embryology (founded and edited by AP Gupta) and Elsevier Science Ltd (London).

the “organising centre” in amphibians (see Sander, 1996).

Seidel proposed a formally similar concept for the insect embryo, but - for reasons quite plausible at the time - he entrusted the wrong centre with generating embryonic complexity. He and his students had discovered that the segment boundaries become visible one after another even in some long germ species, for instance the honeybee. Like some other visible changes (notably gastrulation), this subdivision was found to begin somewhere in the middle of the future pattern, at a location named *Differenzierungszentrum* (differentiation centre). However, Seidel later on went beyond this descriptive concept by crediting the differentiation centre with a physiological task, namely the specification of individual segments that were about to make their appearance anterior and posterior to centre (see Seidel, 1936). This conceptual switch from the “morphological” to the “physiological” differentiation centre was supported by rather complex evidence that became devaluated by subsequent findings (see below). Seidel’s assumption that the course of visible segmentation is strictly linked to segment specification clearly does not hold for silkworm embryogenesis: here the sequential appearance of visible segment boundaries subdividing the germ anlage is preceded by simultaneous segment delineation at the molecular level (Kraft and Jäckle, 1994). Moreover, the data that Seidel quoted in support of his concept are open to alternative explanations based on the progressive commitment of cells to their specific fates (see Sander, 1976).

Doubts concerning the “physiological differentiation centre” were triggered by the first embryonic transplantations (or rather intra-embryonic translocations) performed in insects, using the leafhopper *Euscelis* (Sander, 1960). Together with a large body of other experimental data, the translocation experiments showed that material from the posterior egg pole exerts a long-range effect on patterning over a substantial part of the egg cell: a translocated “posterior centre” did not only influence the character of whole series of segments, but also their polarity - irrespective of whether or not the series contained the differentiation centre. Moreover, these experiments indicated that the effects of the posterior centre are being antagonized by some influence from the more anterior parts of the egg cell which - by comparison with data subsequently obtained in dipterans - might be called an anterior centre*.

The leafhopper experiments (Sander, 1960) also yielded the first concept of how, in insects, an embryonic “centre” could generate a pattern of different segments - namely via a morphogenetic gradient (Sander, 1960). With increasing distance from the centre, some substance(s) produced there would decrease in concentration, and the different concentrations prevailing along this gradient might locally trigger different genes directing the development of different segments. In order to account for certain experimental results, the additional assumption was required that in the leafhopper both centres generate gradients that can interact in some way.

This formal concept of “polar centres” establishing antagonistic gradients embodies several traits meanwhile documented down to the molecular level in *Drosophila* (see below). However, in hindsight the original concept (Sander 1960) was much too simplistic. Moreover, even several data from the leafhopper itself (e.g. Vogel, 1978) required some conceptual amendment, mainly concerning the abdominal segments which the original model (Sander, 1960) indeed had failed to specify in detail. This may mean that the abdomen derives only its polarity

from the gradient system whereas its individual segments form in the sequential “budding” mode - as *per definitionem* required for the intermediate germ type. A more profound revision might be invited by novel findings on the posterior morphogenetic gradient in *Drosophila* (see below).

The concept of morphogenetic centres at the embryo’s poles was soon to receive support from experiments involving a variety of other insect species (see Sander, 1976), especially beetles and lower dipterans (Nematocera). In the latter (midges etc.), each end of the egg cell, anterior as well as posterior, can experimentally be caused to adopt the patterning program of the other, whereby “double abdomens” and “double cephalons” result (Yajima, 1960). This proof of polar influences was followed by the demonstration that newly laid chironomid eggs harbour at the anterior oocyte pole some kind of RNA serving as “anterior determinants” of pattern formation (Kandler- Singer and Kalthoff, 1976).

In higher dipterans (Brachycera, flies) the first evidence for pattern specification being influenced by both egg poles came from ligation experiments in blowfly embryos (Herth and Sander, 1973); the segment patterns obtained were definitely incompatible, on the other hand, with the “mosaic egg” hypothesis. Further evidence for polar influences on patterning came from the mutant “double posterior” or “double anterior” embryos (resembling the chironomid “double monsters”) that were found in maternal effect mutants of *Drosophila* (Bull, 1966; Lohs-Schardin and Sander, 1976, for details see Lohs-Schardin, 1982).

These *Drosophila* mutants heralded the dawn of a new epoch of developmental biology, characterized by large-scale research on animal species that are amenable to genetics and hence to ever more sophisticated molecular methods. This epoch was initiated by the meticulous analysis of *Drosophila* patterning mutants by Lewis (1978) and Nüsslein-Volhard and Wieschaus (1980) recently acknowledged by a Nobel prize. The data accumulated since their pioneering publications are so overwhelming in both quantity and complexity that only a few can be outlined here; for more detailed information see e.g. StJohnston and Nüsslein-Volhard (1992), Bate and Martinez- Arias (1993), and Carroll (1995).

The molecular patterning concept that has emerged is a hierarchical cascade of interacting regulatory genes, provided with polarity by simple spatial cues from the egg poles*. The successive levels of the cascade produce increasingly complex spatial patterns of gene expression even before any segments become visible. The first step in this process is based on the *bicoid* mRNA localized at the anterior pole of the *Drosophila* egg cell. This anterior “organising centre” yields a gradient of the *bicoid* protein serving two functions. (1) It acts as a morphogenetic gradient that specifies the anterior body segments by locally activating the appropriate genes of the second level. (2) It shapes a posterior morphogenetic gradient specifying the posterior segments. This gradient consists of the *caudal* protein and arises by translational control: the *bicoid* protein is capable of inhibiting translation from the evenly distributed *caudal* mRNA and this leads to a gradient of nascent *caudal* protein which has its maximum where *bicoid* concentration is minimal, i.e. posteriorly (Rivero-Pomar et al, 1996).

The morphogenetic function of the *caudal* gradient remained hidden for some time because of an additional complication that can be linked to a step in the evolution of insect patterning

* Note that, for brevity, these and all subsequent considerations will be restricted to longitudinal patterning.

mechanisms, namely the transition from intermediate to long germ development. The posterior centre, apart from inducing the germ line, produces a protein encoded by the *nanos* gene. The *nanos* protein serves to repress the synthesis of yet another protein (encoded by the gene *hunchback*) that in turn would block posterior patterning based on the *caudal* gradient (as described above). This complication may have arisen from a short or intermediate germ ancestor where the repression of *hunchback* was a precondition for the sequential formation of the posterior segments. If so, this repression had to be maintained during transition to the long germ mode since otherwise the abdomen would have been lost in this transition. It might be interesting to check whether the leafhopper data can be reinterpreted on this basis.

These considerations have implicitly paved the way from the evolution of concepts to that of patterning mechanisms. As a crucial component of these mechanisms, the HOX complex of "positional" genes will be considered here*. In *Drosophila*, the unique character of each segment (its "identity") depends on the activities of some members from a set of master genes (or selector genes) known as homeotic genes. Mutants affecting their function (see Lewis, 1978, Carroll, 1995) lead to "homeotic" transformations of the a restricted body region, causing for instance the third thoracic segment to look like a copy of the second, or the antennae like legs. The activation of these genes at the proper location in the early embryo is based on the primary bipolar gradient system that also directs segmentation. On the chromosome, the homeotic genes are arranged as a linear cluster named the HOX complex (split in two parts in *Drosophila*). In this complex, the individual genes - together with the nucleotide sequences needed for their proper spatial regulation - are lined up in a sequence "co-linear" to that of the body segments whose identity they influence most strongly.

The HOX complex was subsequently found to also occur in many other animal groups, and thus must have been highly conserved during evolution (see Akam et al, 1994, Carroll, 1995). The individual HOX genes mediate the position-dependent activation of different "batteries" of target genes. The latter then shape those organs that are appropriate for the respective position in different body plans. As shown by its taxonomic distribution, the HOX complex obviously antedates not only the divergence of the arthropods from related phyla, but even the divergence of proto- and deuterostomians. Consequently the HOX complex may provide a criterion by which all metazoa might be defined as a group (the "zootype" of Slack et al, 1993).

Another highly conserved system of "positional" genes seems now to emerge for the dorso-ventral axis. This system may serve

for inferring the way by which the earliest deuterostomians derived from protostomian ancestors. Contrary to some more sophisticated concepts, this transition must have occurred by a bodily rotation around the animal's longitudinal axis, i.e. by using the former dorsal side as the new ventral side. The argument rests on the fact that in insects and amphibians the dorso-ventral axis is being defined by two groups of mutually inhibitive genes - but the genes defining dorsal in insects are defining ventral in amphibians (Arendt and Nübler-Jung, 1994, De Robertis and Sasai, 1996).

These examples document an amazing conservation of (positional) genes during the profound evolutionary changes in body shape that enable us to distinguish vertebrates from insects. To contrast this molecular conservation, some examples of molecular innovation during evolution will now be outlined to close with. Gene duplication followed by modification of (at least) one descendant gene is an accepted mode of genetic innovation, but insects demonstrate that not only modified genes, but also the modification of regulatory interactions can play a paramount role in evolutionary innovation. This is evident from several genes that in all insects are involved in patterning the central nervous system but in *Drosophila* are additionally involved in the long germ segmentation cascade that must have arisen late in evolution. This cascade also involves two genes located within the HOX complex. They share characteristic sequences with the HOX genes but act much earlier and in different ways. Both may be considered HOX gene descendants put to novel regulatory functions. One of these genes is *bicoid* which so far has not been found outside the higher dipterans and thus may have acquired its basic patterning function late in phylogenesis. The other gene is *fushi tarazu*, involved in gene regulation at a peculiar level of long germ segmentation (defined by "pair-rule" expression); this gene seems to have evolved about ten times faster than the typical HOX genes (Akam et al, 1994) - an example of a "runaway" gene assuming new regulatory functions?

Finally, it was also changes in developmental gene regulation that have enabled *Drosophila* research to play a singular role in the discovery and analysis of the HOX complex. In both arthropods and vertebrates this complex directs the regional differentiation of the central nervous system, but it is only in insects that - owing to a divergence of regulation between the two phyla - the HOX complex directly controls the patterning of the body surface. Mutations in the latter function - leading for instance to four-winged flies - have triggered much of the molecular approach now revolutionizing our concepts of embryonic patterning mechanisms in insects and metazoans in general.

INTERNATIONAL COLLABORATION AMONG NATIONAL ENTOMOLOGICAL SOCIETIES

James H. Oliver, Jr.

Institute of Artropodology and Parasitology, Georgia Southern University
Statesboro, USA

Internationalism and isolationism tend to alternate over time. Most recently there have been disturbing signs of overzealous nationalism which when taken to extremes can cause serious problems. In spite of some recent examples of strong national, tribal, ethnic, and religious discord around the world, I believe that the trend toward international cooperation will prevail. Interdependence continues to increase among people of the world and likely will accelerate as the "information age" expands. The Internet allows low-priced instant electronic communication; its popularity, the increase of multinational business ventures, and the gradual recognition that people of all regions share more similarities than differences makes national isolation an anachronism. The revolution in electronic communication is only beginning to be felt and the boundaries of distance are being eliminated. Information is being democratized. We biologists, of course, have long realized that the natural world is oblivious to political boundaries. Global interconnections of environmental and other issues demand that we biologists play a leading role in educating and convincing people, and thereby politicians, that all of us truly are passengers on spaceship planet earth. We must work together to achieve sustainable development and improvement of the quality of life for all people.

Insects, ticks, and mites are the most numerous animals in species diversity and numbers and have tremendous direct and indirect economic importance. Because of this, entomologists may have a greater opportunity than other biologists to convince government officials and leaders in industry to support international cooperative projects.

Current status of International Cooperation Among Entomologists - International collaboration in science has increased during the past century (Storer, 1970; Luukkonen et al, 1992). Historically, such collaboration may have been due to increasing professionalization of science (Beaver and Rosen, 1978, 1979) and might be related to the formation of scientific societies, meetings, and conferences (Resh and Yamamoto, 1996). A recent study of international collaboration among entomologists involved analysis of authorship of the most recent 100 papers in 115 specialized journals (Resh and Yamamoto, 1996). Multicountry addresses for authors (indicating international collaboration) were recorded in 9.6% of articles examined. Whereas, frequency and success of collaborations depend ultimately on friendships, shared interests, available resources, and other subjective values, it seems likely that conferences, congresses, and scientific societies might play a role in initiating interactions among entomologists. For example, there is no doubt in my mind that the XX International Congress of Entomology will provide an opportunity and stimulus for international collaborations and that productive projects will result.

The Council for International Congresses of Entomology is the organization that provides for the continuation of these con-

gresses every four years. The Council has served entomology well. The question I raise today is whether the global entomological community seeks an expanded role for the Council and/or formation of another organization devoted to goals other than the responsibility of the international congresses every four years? Such goals might involve coordination of activities such as exchange of entomological scholars among countries, exchange of entomological journals, reciprocal memberships in national entomological societies, exchange of newsletters among national societies, issuance of position statements (biodiversity, pesticides, etc.), and other activities. Such a Federation of National Entomological Societies might also assist and promote joint meetings between member Societies, help improve education as well as advise on issues of entomological importance, promote programs and educational opportunities for professional entomologists (students included), improve intercommunication between Societies such as development of a directory to include officers and committees of member Societies, promote networking among members and journal editors, ensure maximum distribution of information on job opportunities, educational opportunities, promote exchange of entomological specimens, ensure exchange of information on any fast-breaking developments between member Societies, to act where possible as one voice, and develop joint policy action statements on such topics as animal welfare, scientific ethics, etc.

On the other hand, perhaps the establishment of a Federation of National Entomological Societies is not desirable or feasible at this time. If not, individual entomological societies might be persuaded to increase their interest and actions supporting international entomological activities. The Entomological Society of America (ESA) has increased its international activities during the past several years. Of the approximate 8,500 members of the ESA, 938 are from outside the United States. The ESA has a standing committee devoted to international affairs and a special representative for international affairs. The Society also has an excellent Library Enhancement Program to aid entomological libraries and scientists in several regions of the world where economic conditions preclude subscriptions to five journals published by the ESA. The gratis journal program is sub-divided to Sub-Saharan Africa, Central Eurasia (including newly independent countries of the former Soviet Union), and Latin America. Most of the libraries do not receive all five journals, although some do, but receive the journals most important for their speciality. For example, a medical library would receive the *Journal of Medical Entomology* whereas libraries devoted to agriculture would receive the *Journal of Economic Entomology*, etc.

The ESA also recently hosted an exchange entomologist, Dr. Bella Striganova, for six weeks with partial support of a grant from the American Association for the Advancement of Science (AAAS). The purpose of the visit was to exchange information on how the science of entomology is organized in the USA. For

example, how the ESA, universities, industry, and government interact to provide an infrastructure for the science. The ESA and many individual entomologists acted as Dr. Striganova's guides and teachers through this process. Hopefully, the information gained from the experience is being transferred to Russia and will be of help.

Further evidence of ESA's commitment to international cooperation among entomologists is the existence of the International Affairs Committee. That committee recommended and the Governing Board endorsed a change in the Society's Constitution to reflect a more global mission and scope. The modification heightens the commitment and responsibility of the ESA to the science of entomology that has no national or political boundaries. Additionally, the ESA Program Committee responsible for the programs at the annual meetings almost always extends invitations to foreign colleagues to present lectures at the meetings. Frequently the expenses of the lecturer are paid by the ESA.

Some of our more conservative colleagues might argue that international collaboration among Societies is a worthy goal, but this is the wrong time to initiate such efforts given the financial climate of most nations and the nationalistic attitude of some politicians. They would remind us that any programs, such as

exchange of scientists, cooperative research efforts, exchanges of publications, etc., would require central coordination through some organization and would need financial resources. In today's world of budget reductions it might be extremely difficult to generate financial support. I would argue that much can be done under existing conditions if there are sincere commitments by a few entomologists and a desire for greater international collaboration by a larger number of our colleagues. Even if a formal Federation of National Entomological Societies is not established much can be accomplished within the organizations of existing national Societies if the will to do so is present.

In conclusion, there is need for leadership to act as a catalyst in facilitating programs that encourage international collaboration among entomologists, although we all understand that ultimately success depends on individual initiatives. I have restricted my lecture today to allow time for a short meeting of those who may be interested in discussing international collaboration among entomologists and what steps should be taken.

Acknowledgements - Gratitude is expressed to Harry Bradley, Kaye Meckley, and Ray Everngam of the Entomological Society of America headquarters staff for providing information about the ESA's international activities.

ENTOMOLOGY INTO THE THIRD MILLENNIUM

Laurence A. Mound

The Natural History Museum, London, U.K.,
and CSIRO Division of Entomology, Canberra, Australia

Science is a product of the societies that support it. However much we might like to think of science as an independent international system of idea generation and testing, the fact remains that it is developed by and paid for by the society in which we happen to live and to which we and our families subscribe. Not all societies have shared, nor will share in the future, our views on evolutionary biology, natural history, or the freedom to ask questions about natural processes. The future of entomology is thus as much in our hands as members of society as it is in our hands as scientists.

The group photograph of the First International Congress of Entomology, taken in Bruxelles in 1908, epitomises the confidence and cohesion of our predecessors at the start of the 20th century. Broadly speaking, these participants belonged to one race and one social group - relatively wealthy, middle-class, and European. They knew each other; they shared each other's motivation and mores to a greater extent than our current entomological colleagues. But at what cost? The vast majority of mankind was excluded from this social group, and any knowledge acquired by mankind from outside the intellectual heritage of Greece and Rome was similarly excluded. To a large extent, entomology was a rich white-man's game. Any knowledge about the natural world, even pest control, generated by cultures in Australia or Africa, China or India, remained uncommunicated, sometimes despite written literature extending back for 3,000 years. Our science at the beginning of the century thus reflected most of the European social divisions then current; most of the women in the photograph are spouses, despite individuals such as Eleanor Ormerod, one of the first great economic entomologists, having made formidable scientific contributions.

Consider the changes this century. At one of our International Congresses participants will come from 70 or more countries, representing most of the ethnic and language groups to which our species has given rise, and entomological congresses in China or Brasil attract several thousand local participants. Entomologists now come from the full range of society, from peasants to plutocrats, and our president and vice-president are both women. But increasing numbers and diversity of individuals and sub-disciplines poses two fundamental problems for the future, the funding of an ever expanding array of knowledge, and then communication between this group of people as it continues to expand both numerically and socially.

Consider again that group photograph of 1908. The participants exude confidence in themselves and their society. In the words of the period, 'the world was their oyster'. The natural world had always been there; it was available to be explored, and provided a limitless source to be exploited. Not recognising the destruction already effected by mankind's territorial and population expansion, such as the extermination of larger animals across the Pacific islands or the deforestation of parts of China, they could not foresee the damage that would follow human popu-

lation increases resulting from pest and disease control. Malthus was for academics, not for the investment class to which most entomologists belonged. Our generation recognises the problems, as well as our professional responsibilities for ameliorating the conditions of life for future generations, but it remains to be seen if we have the political courage to do anything.

This then is the starting position for entomology into the third millennium: increasing numbers of entomologists and a burgeoning literature in many languages and sub-disciplines, with resultant problems in communication; increasing diversity and expense in the techniques employed to study insects, with resultant problems for funding the increased costs of all but the most vital of activities; decreasing diversity of insects as natural habitats are destroyed, with resultant general impoverishment of the human environment as well as increasing constraints on our range of insect research options; and an increasing human population with all the social and educational problems that implies. This is surely the reality? Business will not be 'as usual' into the next century, although we cannot be sure what business will actually be like. We cannot predict the future, but we can certainly plan and attempt to create that future - instead of behaving like the images in the 1908 photograph, confident that the world will continue to supply their needs.

We cannot be sure where entomological research will lead, the investigation of the structure and functioning of insects as well as their relationships to each other and the rest of the world. Such investigations depend on serendipity, and the fertility of the minds that are involved in insect science. But we can look at some of the problems outlined above and consider our possible reactions. In considering the future, it is no co-incidence that the three Symposia and Workshop organised in Section 24 of this International Congress were each about human problems rather than science in a narrow sense - education, communication and quarantine. Because if we fail in these areas, then we will further limit the resources available to society for studies on insects.

Scientific research has always been expensive. The mathematicians and astronomers of ancient Egypt or India must have cost their wealthy patrons dearly. Wealthy patronage, often largely for reasons of self-interest, continued to be the funding source into this century, until it was superseded by state funding on the grounds of generalised public good. But the costs of science continue to rise as research workers discover new methods that open up new horizons for exploration. And the level of funding available for science from the public purse cannot be expected to keep pace with this rise in costs - nor yet with the rise in research possibilities. The funding base must inevitably level-off, leaving governments as well as each of us with ever more difficult decisions on priorities.

In most countries, the state has now reverted to the self-interested views of many wealthy patrons; government accountants

expect to see an early financial return on any investment of public money in scientific research. Henry Ford is reputed to have said that history is bunk, but at times our politicians and their accountants give the impression that they consider that the future is bunk, or at least has no existence beyond the period of our current grant. This places constraints on planning biological studies, because these often need a long lead-time. As a result we need to develop more dynamic ways of planning research such that specific short term results are obtained that are useful to our fundees, whilst we progress toward the more general objectives that we ourselves consider to be important. Regrettably, scientists rarely make good politicians.

The diversification of science certainly involves serious financial problems. For example, as a museum taxonomist my only expensive research tool (apart from the museum collections themselves) for 30 years was one high-quality, phase-contrast microscope. However, my capital and recurrent expenditure rose sharply in recent years in line with expanded research possibilities - computers of ever increasing sophistication, equipment for rearing and observing behaviour, facilities for field research, and participation in DNA methods for distinguishing taxa. This expansion in research costs inevitably results in fewer people being employed. Similarly, entomological libraries in Britain find that the cost of journal subscriptions has been rising at nearly four times the rate of inflation; the cost of binding and accommodating books has similarly increased, and this at a time when the number of publications on insects is rising rapidly. As a result, many librarians must annually cull their journal and book purchase lists in order to reflect only the work currently in progress in their institutes; it is not possible for any institute to maintain a complete collection of all books and journals referring to insects. The CSIRO library in Canberra houses almost 500 serials concerned in some measure with insects, but China alone now publishes annually the equivalent of half of that number of periodicals containing information about insects.

The application of 'market forces' to the funding of research has unforeseen problems, because the entomological 'market' itself is not stationary. At one time the market was clearly discipline-orientated, with most universities and agricultural research organisations having an 'entomology department'. Now, however many departments have a different orientation - the life sciences, or plant protection for example. Many people working on insects in fields such as plant production, public hygiene, conservation, or water quality, do not automatically regard themselves as 'entomologists'. As a result, the market for books is changing as the traditional discipline-orientation of these potential purchasers changes. One major publisher of review journals has reported annual sales reductions over the past few years of 2% per year, with profit losses nearer 5% per year. An accountant can readily calculate that each paper published in such a commercial journal must generate more than 5,000 US\$ in gross sales. The market for entomological information is thus shifting, and individual costs are escalating; this has downstream effects both on how we plan to distribute information in the future, and how opportunities for research are perceived.

The next generation of students needs to be attracted to insects, as objects of interest, beauty and importance to their lives. Didactic methods of teaching are no longer appropriate in this computer and television driven age. We need methods that carry greater impact in communicating to students our knowledge, excitement and understanding of the natural world, using good images in books and on computers. This is now happening for younger children. Why then do our teaching methods for older students remain so prosaic? Students are expected to learn

considerable detail about insect structure - all from books. In medicine, it is already possible to obtain on cd-rom complete dissections of the human body obtained from serial sections. In the future, student surgeons will be able to practise dissections on such a 'virtual-body' - a computer image. Why is there no cd-rom compendium of insect structure available, so that students could search at their computer terminal for the images and information they need - on mandibular structure or wing venation. Increasingly students prefer to use terminals rather than libraries, and we need to plan our teaching accordingly. By imparting basic facts more efficiently than in the time-honoured system of lecturing and taking notes, we could leave more time for teaching - that valuable practice of stimulating interest and thought in others.

Virtual imaging must have a significant future in entomology. Already it is possible to 'grow' on screen a virtual cotton plant, and to vary growth parameters. This technique can be used, for example, to investigate the possibility of improved plant architecture in order to improve the interception of light by leaves, and thus create a specific objective for plant breeders. But the next stage in virtual imaging will include the effect on plant growth of insect pests, and subsequently the effect of parasites on pests. The possibility of carrying out virtual insecticide trials on screen, varying the droplet sizes, wind speeds, concentrations and frequency, with only the most effective treatments needing to go through the expensive process of 'ground-truthing', holds out the prospect of reduced costs, shorter experimental periods and lower usage of chemicals.

As a small science, entomology is scarcely keeping pace with the changes in communication. Many thousands of scientific journals are now available via the Internet, with copies available by fax on request. More than 700 scientific journals worldwide are now published on-line, and the number is increasing rapidly. At least one such journal, in biochemistry and medicine, has the facility of reproducing on screen abstracts of all of the papers quoted in the reference lists of each of the papers it publishes - a complex system of hyperlinks that is currently too expensive for entomology. But entomology, and particularly taxonomic entomology, is often concerned more with publication in terms of priority rather than in terms of information dissemination. Libraries are increasingly expensive to build and maintain; the future for information dissemination thus seems to lie in electronic methods, although the problems of priority and archiving such material have yet to be solved.

The new check-list of Lepidoptera from Australia, a vast archival source involving over 25,000 names, will be published on cd-rom by CSIRO this year. But large quantities of information about insects, particularly that which is required by only a few workers worldwide in any one year, could be communicated to the users much more cost-effectively using this technology than as books. Electronic information and identification systems are being produced in entomology that will go far to assist global communication about insects. Bear in mind the many thousands of periodicals and books in which information about insects is now published - and few of the hundreds published in Asian countries are available in Africa or South America. Increasingly we all turn now to our terminals, rather than to our libraries, to find out what is going on in our own fields as well as in surrounding fields of biology.

Communication between the many sub-disciplines of insect biology becomes ever more difficult as the complexity of our studies expand. It is doubtful if the traditional all-embracing approach to entomological training remains valid, particularly if the students are themselves intended to contribute professionally

at one or more of the current cutting edges of insect science. Increasingly, students at doctorate level are unable to recognise members of common beetle or fly families. But is this such a great loss? The holistic ideal is our aim, because ultimately we try to understand how an individual and its species functions, how it contributes to ecosystems, and how the interactions between species and ecosystems have evolved and facilitated evolution. We examine the present in detail, to understand the past and predict the future. But there are ways of achieving such holistic ends without expecting every student to master the whole range of insect science. Increasingly, research grants given for collaborative and inter-disciplinary work bring together our sub-disciplines, with mutual enlightenment and stimulation. Understanding the diversity, functioning and evolution of systems through collaborative work is likely to be of greater benefit to mankind than concentration on particular taxa, even one as all pervasive as the Insecta.

Meanwhile the world around us will presumably not become any less complex. The human population is likely to continue to rise, the natural world is likely to continue to become more

depauperate, and competition between nations for limited global resources is likely to become sharper. The global marketplace has led to a global pest and disease spectrum. Already, all of the 40 major weed species of the world are found in Australia, as are 20 of the 35 most important thrips pests. A similar picture could be found in many other countries. This places strains on our quarantine services in the ever unpopular problems of controlling the international movement of people and their produce. Our increasing mobility places at risk not just our crops but also our natural resources. Perhaps one major growth area for entomology will be in association with the expanding tourist and leisure industries. We all need the benefits of natural environments to recover from the stresses of industrialised living. Through enhanced conservation programmes, involving improved education and communication about biological diversity, both its commercial and intellectual value, perhaps we can maintain our research budgets, contribute usefully to society, and continue with that human activity we all find most pleasurable and stimulating - the study of insect life.

A "TOTAL EVIDENCE" CLADOGRAM FOR THE
ARTHROPODA
W. Wheeler

ABSTRACT NOT RECEIVED

01-001

THE ARTICULATES: THE METAMERE AND TAGMA CONCEPTS
IN THE LIGHT OF MODERN DEVELOPMENTAL MORPHOLOGY
J. Zrzavý
Inst. Entomol. + Fac. Biol. Sci., Branišovská
31,
370 05 České Budějovice, Czech Republic

Processes governing the parasegmentation, segmentation, and subsequent tagmatization, well known in *Drosophila*, are compared with the fragmentary knowledge of these phenomena in other arthropods, onychophorans, and annelids. All arthropod segments are probably homologous among all arthropods; the concurrence of both the parasegments and segments is probably probably characteristic of all the arthropods and annelids. The annelid segments (and segments of the hypothetical soft-bodied arthropod ancestor) cannot be identified with parasegments. The alleged Snodgrassian "primary segments" (antecosta-antecosta) are identical with no identified developmental body metameres in arthropods. Evolutionary morphology as well as embryology of crustaceans and hexapods (cell-lineages, expression of segmentation and homeotic genes, mitotic domains) suggest that the basic boundary subdividing the mandibulate body runs within the mandibular segment, between protocephalon (pregnathal region) and protocorm (trunk incl. maxillary segments). The "typical" mandibulate head is not developed in all the Mandibulata (Crustacea + Hexapoda + Myriapoda) and has evolved several times in parallel. Postmaxillary trunk tagmosis of anostracans may be homologous to that of insects (10-11 pregenital trunk segments with Antp, Ubx, and abdA genes coexpression, 2 genital segments with AbdB gene expression).

01-003

THE GROUND PLAN AND BASAL DIVERSIFICATION OF
HEXAPODS
N.P. Kristensen
Zoological Museum, University of Copenhagen, Denmark

The tagmosis pattern is the most obvious groundplan autapomorphy of the Hexapoda as usually delimited, but evidently an ad hoc explanation is, then, required to account for the small number of abdominal segments in the Collembola. The problems inherent in a detailed reconstruction of the hexapod groundplan are inextricably linked with the problems concerning the status and affinities of the conventionally recognized taxon 'Diplura'. Do the 'campodeoid' and 'japygoid' lineages really constitute a monophylum? If so, are its closest relations with the Entognatha s.str. (Collembola+Protura) or are they with the Insecta s.str. (Archaeognatha+Dicondylia), rendering entognathy homoplasious? If not, do all 'entognathan' lineages constitute a 'Hennigian comb', or are the 'japygoids' the sister group of the Insecta s.str. as has recently been suggested? While the monophyly of the Dicondylia seems to gain widespread acceptance, the question about the sister group of the winged-insect clade remains open. Are the families currently grouped together in the 'Zygentoma' really a monophylum, or are the Lepismatidae closer to the Pterygota than the Lepidothricidae which allegedly have retained a 'ligamentous' cephalic endoskeleton? And where do the Nicoletiidae fit in? The basal split within extant Pterygota arguably remains unsatisfactorily resolved. An in-depth examination of the Ephemeroptera/Odenata/Neoptera trichotomy is called for. Emphasis should be placed on non-alar characters which lend themselves to polarization by the outgroup criterion.

01-004

HOW TO FIND AND TEST RELIABLE HIGHER LEVEL CHARACTERS IN INSECTS

Jarmila Kukalova-Peck,

Earth Sciences, Carleton University, Ottawa K1S 5B6, Canada

The higher systematics of Insecta is presently experiencing confused times. Much energy goes into sophisticated **processing** of quite uncertain characters, but very little into **primary research** on characters, the morphological backbone of phylogeny. Parsimony (aiming not for a grade of A, or F, but for C-) works well enough for specics, but is not good enough at higher levels. Higher level apomorphies are nodal transformations which occurred from ca 600-200 m.y. ago. They were few and are now often obscured in modern insects. They are mostly interlocked in old major structures, such as legs, wings and mouthparts, and reachable by two approaches: 1. Panarthropod comparative anatomy, and 2. Developmental genetics. Both painstakingly gather evidence for the vanished, nodal ancestor of a taxon, known as a groundplan, from which all members can be derived. Used by Snodgrass and Hennig, the groundplan is the best way towards understanding major structures and obtaining reliable rooting for directional morphological transformations. It reveals long series of character changes in clades of orders, suborders and superfamilies. Recently, cross-testing with genetics has already confirmed the proposed basal anatomy of the leg (polyamy, mandible, leglet, proleg, mouthparts and the wing identity: JKP, *The Insects of Australia* 1991). Present progress in pterygote phylogeny is in the improved homologisation and in new groundplans of the higher taxa based on wing venation and wing articulation. A new, improved phylogenetic tree of pterygote orders is offered.

01-006

THE MANDIBULAR ARTICULATION OF MAYFLIES (INSECTA: EPHEMEROPTERA) AND ITS IMPLICATIONS FOR THE PHYLOGENY OF THE BASIC PTERYGOTE LINEAGESA.H. Staniczek

Universität Tübingen, Zoologisches Institut, Lehrstuhl für Spezielle Zoologie, Tübingen, Germany

To unravel the groundplan condition regarding the mandibular articulation of Ephemeroptera several basal mayfly nymphs have been investigated by manual preparation as well as microscopic sectioning. The results indicate the presence of three points of mandibular attachment to the cranium in the groundplan of Ephemeroptera. The anterior point of attachment is represented by a lateral mandibular groove that fits into the inner margin of the inflected cranium. This structure is interpreted as an autapomorphy of the Ephemeroptera. The middle and posterior points of articulation are homologized with the anterior (secondary) and posterior (primary) mandibular joint of other Dicondylia.

The development of an additional mandibular attachment in Ephemeroptera is interrelated with a different position of the anterior tentorial arms. The anterior tentorial pit in mayflies has a more posterior position compared to the condition in other Dicondylia. The cranial condylus of the secondary mandibular joint in mayflies is located close to the anterior tentorial pit. The backward shift of both anterior tentorial arm and cranial condylus is regarded as an autapomorphic character of the Ephemeroptera, too.

Besides these derived characters the mandible of Ephemeroptera retains the groundplan condition of Dicondylia in several aspects: The secondary mandibular joint is not visible externally, and its cranial condyle is not formed by the clypeus. The primary mandibular articulation is located dorsally of the secondary one, which brings about an oblique axis of mandibular movement. This resembles a plesiomorphic arrangement as it is present in *Zygantoma*, too. In contrast all other Dicondylia have developed an almost horizontal axis of mandibular movement. This character distribution could count for a sistergroup relationship between Ephemeroptera and Metapterygota.

01-005

LIMB BASE MORPHOLOGY OF THE ARTHROPODA: A REVIEW OF COMPETING MODELSG. CASSIS, G.D. EDGEcombe, G.D.F. WILSON AND M.R. GRAY
Centre for Evolutionary Research, Australian Museum, Sydney Australia

Recent challenges to the monophyly of the Mandibulata and Tracheata stem from both molecular and morphological data. The theory that insects are derived from a paraphyletic Crustacea has a background in the comparison of derived crustacean limbs (Eumalacostraca) with those of insects. This theory presumes that the Crustacea lack defining synapomorphies. Numerous shared derived characters of Crustacea refute the notion of Crustacea as a grade ancestral to insects or any other arthropod taxon. Homologies of limb base segments across the arthropods have been only partially resolved. Walossek has proposed that the "coxa" of the Crustacea is a new structure, not present in basal arthropods, and not present in the most recent common ancestor of the Mandibulata. Fossil stem group crustaceans have proximal elements of the legs, particularly the "basis", that can be homologised with the stem group chelicerates (e.g. trilobites). The precise identity of the basis in the Tracheata is unresolved. However, the subcoxal and coxal leg elements of the Tracheata are derived characters of that group. The primitive absence of the subcoxa in crustaceans conflicts with the Kukalova-Peck model for leg base homologies throughout the Mandibulata and more broadly Arthropoda. This is supported by the absence of a pleuron in the Crustacea. Furthermore, problems with the polyramous model for basal arthropod appendages are that crustaceans and early chelicerates have a fixed and conservative relationship between endopod, exopod and basis, and lack multiple exites. Therefore, the presence of a stylus or multiple styli is a weak criterion for establishing polyramy at the base of the Arthropoda.

01-007

A "TOTAL EVIDENCE" CLADOGRAM FOR THE HEXAPODA

J. Carpenter (Tifton-United States)

ABSTRACT NOT RECEIVED

01-008

SPECIES NUMBERS OF HEXAPOD GROUPS IN A PHYLOGENETIC CONTEXT
P.M. Hammond
Biodiversity Division, Department of Entomology, The Natural History Museum, Cromwell Road, London SW7 5BD, U.K.

Data on the number of described species currently recognised as valid for major hexapod groups are reviewed, the evidence with respect to actual numbers of extant species examined, and methods for estimating undescribed species numbers critically evaluated.

Hexapod "success" measured in species-richness terms is manifested mainly through a rather small number of endopterygote clades. In discussing this, the following are among the questions addressed: What are the principal correlates of such success in terms of lifeways, aptations and resources utilised? Are recent accounts of how species-richness of the major groups may have varied through geological time reliable? Have some clades peaked already and, if so, why?

MAPPING OVARIOLE STRUCTURE ON THE HEXAPOD CLADOGRAM
J. Buning (Erlangen-Germany)

ABSTRACT NOT RECEIVED

01-009

MAPPING MODES OF EMBRYOGENESIS ON THE HEXAPOD CLADOGRAM
R. Machida¹, Y. Kobayashi², H. Ando¹
1 Sugadaira Montane Research Center, University of Tsukuba, Sanada, Nagano, Japan -2 Department of Natural History, Faculty of Science, Tokyo Metropolitan University, Minamiohsawa, Hachioji, Tokyo, Japan

Comparative embryology of Hexapoda has revealed several characters which appear phylogenetically informative. The distribution of such characters (including among others the cleavage, embryonic membranes, amnioserosal fold, blastokinesis, germ type and germ layer formation) upon a 'total evidence' cladogram will be examined. The Protura are excluded from consideration, since their embryology still remains unknown.

1. The monophyly of the taxon Ectognatha (= Insecta *s.str.*) as well as of the Dicondylia seems to be supported by important embryological apomorphies.
2. Members of the Entognatha share many embryological plesiomorphies, but the common mode of entognathy formation arguably suffices to suggest their monophyly (*i.e.*, it is a synapomorphy of Collembola and Diplura). The Diplura are also recognized as monophyletic on the basis of detailed similarities in entognathy formation in the Rhabdura and Dicellurata, as well as their sharing of an abdomen with only ten segments.
3. Available data from comparative embryology of the Pterygota do not permit far-reaching conclusions on order-level phylogeny. Some comments on pertinent topical problems will be given.
4. Comparative embryology so far supports a hexapod phylogeny formulated as: Entognatha (= Collembola + Diplura) + Ectognatha [= Monocondylia (= Archaeognatha) + Dicondylia (= Zygentoma + Pterygota)].

A MOLECULAR PHYLOGENY OF THE FAMILIES AND ORDERS OF COLLEMBOLA (ARTHROPODA: HEXAPODA) USING THE 18S r-RNA GENE

F. N. Soto-Adames and H. M. Robertson

Department of Entomology, University of Illinois, Urbana, IL, USA.

We investigated the phylogenetic relationships of the Families and Orders of Collembola, with special reference to six groups that traditionally have been problematic, or that have become problematic with the implementation of a cladistic philosophy to the taxonomy of the group. Some authors have questioned the monophyly of the order Poduromorpha, and the supraordinal categories Arthropleona and Symphypleona s.l. In addition, the specific phylogenetic affinities of Poduridae, Actaletidae, and Tomoceridae have not been resolved. To clarify these relationships we obtained complete sequences for the 18S rRNA gene from 21 species representing the families Hypogastruridae, Onychiuridae, Poduridae, Neanuridae, Isotomidae, Actaletidae, Tomoceridae, Entomobryidae, Neelidae, and Sminthuridae s.l., and all four orders. We also sequenced the 18S gene from a jumping bristletail (*Microcoryphia*), and a house centipede (*Chilopoda*), which together with sequences from *Artemia salina* (Crustacea), and *Tenebrio molitor* (Coleoptera) (obtained from Genbank) were used as outgroups in the phylogenetic analyses. Phylogenetic analyses were performed using parsimony. The monophyly of Poduromorpha was supported by all analyses. Support for a monophyletic Arthropleona was ambiguous and cannot be resolved at this time. A monophyletic Symphypleona s.l. was never supported. The placement of Poduridae in Poduromorpha was always supported, but its affinities within the order could not be unambiguously resolved. Most of the iconoclastic propositions of the phylogenetic affinities of Actaletidae were rejected, but the question remains of whether this family is the sister group of Isotomidae or basal to all other Entomobryomorpha. The proper placement of Tomoceridae could not be resolved because in most analyses this taxon clustered with different groups. We attribute the failure of 18S to support the monophyly of groups well supported by morphological characters to differences in rates of evolution among lineages, and to low stemminess in the most parsimonious trees, presumably resulting from rapid radiation in relatively short time spans.

01-013

MAPPING AQUATIC LIFE-STYLES ON THE HEXAPOD CLADOGRAM

G. Pritchard

Department of Biological Sciences, University of Calgary, Calgary, Alberta, Canada

Insects show at least 12 types of life histories in which one or more stages are aquatic. Morphological studies suggest that these aquatic life-styles have evolved several times from completely terrestrial ancestors. In this presentation I map the distribution of aquatic life-styles on the latest 'total evidence' cladogram, and discuss congruences, conflicts, and insights that arise.

01-015

Evolutionary pathways of larval eyes in Coleoptera

Hannes F. Paulus, Institute for Zoology, Dep. of Evolutionary Biology, Vienna (Austria)

Coleopteran stemmata are derived from modified imaginal ommatidia. The plesiomorphic state are probably 7 stemmata (only Dytiscini) as in some other holometabolan orders. But in most families the basic number is 6. An ultrastructural investigation of many coleopteran taxa revealed that the plesiomorphic stemma is a modified ommatidium with an acone crystalline cone, consisting of 8 retinula cells arranged in two levels; the two primary pigment cells are lacking or modified in two undifferentiated comeagenous cells. Such a basic larval ommatidium can be found in Staphylinidae (*Lesteva*) and Lagriidae. In most cases a crystalline cone is lacking or replaced by an epidermal layer of hyaline cells. Further modifications are (1) fusing of single stemmata to double-stemmata or fusion of higher numbers of stemmata with a respective multiplication of cell numbers or (2) multiplication of cells in each stemma without fusion. Diminution of stemmata number can be a consequence of (1) reduction or (2) fusion. Many Staphylinidae, Scirtidae, Pyrochroidae, Cerambycidae and others belong to case 1, some other Staphylinidae (*Atheta*), Elateridae, Cantharidae, and some Tenebrionidae represent case 2. In most Adephaga we find 6 stemmata with higher cell numbers originated by secondary multiplication. A special case is the doubling of cells in all stemmata without reduction of the lens number. So far as I know all Byrrhoidea, Dryopoidea, Elateroidea and Cantharoidea have as a basic situation of 6 double-stemmata each with 16 retinula cells. Starting from this situation the single lens in Elateroidea and Cantharoidea is a fusion of the six double-stemmata. In *Cantharis* we find two groups of retinula cells each consisting of 48 cells (= 3 X 16), in *Drilus* three groups each with 32 cells (= 2 X 16). In all cases we have a total number of 6 X 16 retinula cells. From these differences in cell numbers and cell arrangement I conclude that the single lens eyes in Coleoptera larvae are the result of independent evolutionary pathways.

01-016

PREVENTIVE PEST MANAGEMENT: MANIPULATING EVOLUTIONARY STRATEGIES OF PEST SPECIES

K. C. Kim Frost Entomological Museum, Department of Entomology, The Pennsylvania State University, University Park, PA, USA

The basic paradigm and strategies of contemporary pest management have not changed very much for the last several decades, although the level of pesticide application is moderated. We continue to struggle with pest resistance against pesticides and environmental degradation by agrochemicals. Meanwhile, however, our world has changed dramatically. The planet is now inhabited by 5.75 billion humans with an addition of 100 million per year and the global environment is increasingly at risk because of increasing human activities. In this rapidly changing world we cannot afford to continue this management practice indefinitely.

Pest management should be anticipatory, predictive and preventive as well as managing pest populations. It should take on ecosystem management strategies focusing on the biology and ecology of pests and the biological impact of pests on host plants with the least environmental costs. Pest species evolves in response to the changing conditions of their genetic, ecological and habitat environments, as it continually interacts with other ecological cohorts including host plants. Pest management strategy should focus on manipulating the evolutionary process of pest species to reduce the impacts of pest activities to agricultural production and forest management rather than the population density in the context of ecosystem management. This strategy requires a multi-level approach encompassing the issues of intraspecific variation, demography, community dynamics, and ecosystem process. In this paper the issues involved in intraspecific variation among and within populations of pest species will be discussed with respect to pest management and a new approach to integrated pest management will be explored.

01-018

CONTRIBUTIONS AND APPLICATIONS OF MOLECULAR TECHNIQUES IN PEST MANAGEMENT

Srini Kambhampati

Department of Entomology, Kansas State University, Manhattan, Kansas, USA.

A variety of molecular techniques to study systematics, evolution and population genetics of insects have become available to entomologists during the past two decades. In conjunction, the breadth of applications has also increased to include basic and applied entomology. Of particular interest is the potential use of the emerging molecular techniques to study various aspects of pest insects and natural enemies and apply the information to enhance existing integrated pest management programs. In this presentation, various molecular techniques and their applications will be reviewed with relevant examples from pest insects and natural enemies. The emphasis will be on (a) use of population-level markers to study gene flow in pest insects and natural enemies, (b) use of DNA sequence analysis to infer phylogenies of groups that contain one or more pest insects, which in turn can provide insights into evolutionary pathways of specific traits (e.g., adaptation to crop plants, host range), and (c) use of DNA sequence analysis to infer phylogenies of natural enemies and study the evolution of host range and other behaviors.

01-017

SPECIES CONCEPTS IN PEST MANAGEMENT - THEORY AND PRACTICE

M.F. Claridge

School of Pure & Applied Biology, University of Wales Cardiff, UK.

The importance of biodiversity in sustainable agriculture is widely emphasised and species are generally used as the units of such diversity. The correct identity and recognition of species of insect pests and their predators and parasites is one of the most critical contributions of systematics to scientific pest management.

As Ernst Mayr (1983) has emphasised, the species concept in biology has consistently remained controversial. Traditionally insect species have been defined in terms of clear morphological differentiation. In practice most species of insects are still described on a basis of dead preserved material and remain *morphospecies*.

Ideas of species as reproductively isolated entities in the field led to the development of the many variants of the *biological species* concept. An important consequence of the biological species is the recognition of reproductively isolated cryptic or sibling species that show no clear morphological differentiation but which are reproductively isolated. In practice species are characterised by markers that may be morphological, cytological, behavioural, molecular, *etc.*, but which indicate reproductive isolation.

Difficulties with 1. asexual and obligately parthenogenetic forms, and 2. populations isolated in space (allopatric), together with a desire to apply cladistic techniques have led to the rejection of the biological species in favour of a *phylogenetic species* concept by many systematists. Problems for pest management of such a change will be considered. They include particularly the possibility of ignoring sibling species. Examples from groups of tropical insect pests and their parasitoids will be discussed.

01-019

SYSTEMATICS RESEARCH IN SUPPORT OF BIOLOGICAL CONTROL

M. E. Schauff and J. LaSalle

Systematic Entomology Laboratory, Washington, D.C. and International Institute of Entomology, London, UK

Systematics provides critical support for biological control by providing baseline information. In this paper we summarize how systematics information impacts biological control with emphasis on how advances in methods, theory, and information transfer provide the opportunity for enhanced interaction between systematists and biological control workers. We also document how inadequate systematics adversely impacts control programs.

Most insect groups are poorly known, and information concerning species must often be predicted from their closest relatives. Phylogenetic systematics, by providing testable hypotheses of relationship within groups, gives workers a framework of relationships with which to make these predictions about native home host range, natural enemies, environmental tolerance, biology, behavior, etc.

Molecular systematics studies can complement more traditional methods and have allowed the solution of species and subspecies level problems of importance to biological control programs, particularly the discrimination of sibling species, geographical races and biotypes.

Advances in informatics (distribution of information via electronic means like the World Wide Web) promises to make the data from systematic studies more readily available to a wider audience and make it easier for non-taxonomists to make informed decisions about taxonomic problems.

Despite many recent advances in methodology and technology, great gaps still exist in our knowledge of pivotal groups used widely in biological control. Many areas, even in relatively well collected regions such as Europe and the United States still contain many undescribed taxa of potential biocontrol importance. In addition, there are numerous groups which are heavily utilized in biocontrol, but for which modern comprehensive systematics studies are still lacking. We see no easy solution to this problem beyond increasing funding for basic systematics research and closer coordination between systematists and biocontrol workers.

01-020

MOLECULAR PHYLOGENIES AND THEIR APPLICATION TO BIOLOGICAL CONTROL

J. Heraty, B.C. Campbell¹, J.D. Steffan-Campbell¹

Department of Entomology, University of California, Riverside, CA
USA - ¹ Western Regional Research Center, USDA-ARS, Albany, CA
USA

For the use of parasitoids or predators in biological control, molecular systematics has or will have impact on two important areas: 1) the identification of species or populations, and 2) the characterization of monophyletic lineages, whose members could share similar biological attributes. Chalcidoidea is likely the most important group of parasitic wasps for biological control programs; however, little progress is being made toward understanding the relationships of the included organisms using morphological techniques alone. Fundamental questions exist regarding the monophyly or relationship of most of the major assemblages such as the Aphelinidae, Eulophidae, Eupelmidae, Trichogrammatidae to name a few. Molecular techniques being used for the phylogenetic analysis of Chalcidoidea are reviewed, with an emphasis on understanding the monophyly and relationships of the Aphelinidae using nucleotide sequences of 18S, 28S D2 expansion and ITS2 regions of the rRNA transcript. Morphological features are compared with the resulting trees. Attributes of each of the genetic regions are discussed with regard to their application for the study of relationships within genera of Aphelinidae.

01-022

LYGUS BUGS: THE INTERFACE BETWEEN ANALYTICAL SYSTEMATICS AND PEST MANAGEMENT

R. G. Foottit, M. D. Schwartz

Biological Resources Division, Centre for Land and Biological
Resources Research, Agriculture and Agri-Food Canada, Ottawa,
ON, Canada

Species of *Lygus* (Heteroptera: Miridae) cause economic losses to a wide range of crops in North America and Europe. As a consequence of its impact on agroecosystems, *Lygus* continues to be the subject of much basic and applied research. Yet, until recently, there has not been a reliable model of the relationships among the species, nor have there been reliable methods to routinely identify the species; this is largely due to generally subtle differences among and a great deal of variability within taxonomic characters. We report on a broad systematic analysis of *Lygus*, using morphological and molecular data and morphometric and phylogenetic methods, focusing on the points of conflict and congruence observed between morphological and molecular approaches. Comprehensive systematic analyses are shown to provide a testable framework upon which life history strategies can be studied and biological control efforts and identification technologies can be developed. This approach has allowed for a focus on specific questions about the phylogenetic placement of the economically important species, their geographical distributions and potential host plant ranges; all are issues of importance in the selection of biological control agents, regulation against the introduction of new pest species and the development of new crops.

01-021

RICE INSECTS AND PEST MANAGEMENT:
IS TAXONOMY IMPORTANT?

M.R. Wilson

Department of Zoology, National Museums & Galleries of
Wales, Cardiff, CF1 3NP, UK

Rice (*Oryza sativa*) is by far the most important cereal crop grown in tropical countries. Over 800 insect species are known to damage rice while it is growing or in store. A considerable amount of information on rice pests, and their predators and parasitoids has been amassed. This has enabled increasingly sophisticated integrated management programmes to be developed, particularly as a result of reductions in agrochemical usage. To what extent have these advances in pest management been due to taxonomic knowledge? Can successful management of pests be achieved without taxonomic studies? This idea is examined with rice insects providing examples for discussion.

01-023

DISSEMINATING BIOSYSTEMATIC INFORMATION:
YESTERDAY, TODAY AND TOMORROW.

F. Christain Thompson

Systematic Entomology Lab., USDA
NHB-168 Smithsonian Institution
Washington, D. C. 20560 USA

From Linnaeus to today, the content of BioSystematic Information has not changed much. Likewise, the demands of users: they want to know what it is, what it does, and when and where it does it. What has changed is the magnitude of information, from a few thousand to millions of data points, and the media on which to disseminate it, from the printed page to a full range of electronic formats, such as CD-ROM (Compact Disk-Read Only Memory) disks and WWW (World-Wide-Web) on the Internet. This explosion of information and multimedia, at a time when support for Systematics is declining but awareness of the importance of BioSystematic information for the sustainable use of Biodiversity is increasing users' demands, provides the challenge for the new century. How the systematists in Washington are meeting the challenge is illustrated and demonstrated with products, from on-line databases to expert identification systems.

Plant Protection
The Biosystematic Impediment to Success
by
Professor Tecwyn Jones O.B.E.
Director, Technical Secretariat of
BioNET-INTERNATIONAL
at CAB INTERNATIONAL Bakeham Lane Egham
Surrey TW20 9TY

Attention is drawn to the vital importance of sound biosystematics in plant protection programmes, where economic and environmentally friendly systems have become imperative to lower crop production costs and achieve sustainable agricultural development. The need for user-friendly aids for identification for plant protection personnel and quarantine services is emphasised whilst recognising the continuing and increasing need for up-stream biosystematic research and keys from which such aids can be developed. The role of BioNET-INTERNATIONAL in removing the present biosystematic impediment to improved plant protection and quarantine is described.

THE EVOLUTION OF REPRODUCTIVE AND SOCIAL BEHAVIOURS IN
COCKROACHES: A PHYLOGENETIC ANALYSIS
P. Grandcolas
URA CNRS 373, Station Biologique, Université de Rennes, France

Cockroaches present a diverse array of reproductive and social behaviours. Reproductive behaviours comprise oviparity, ovoviviparity and viviparity. Oviparous species are themselves diverse with respect to the time females carry their oothecae and the way they provide them with water. Social behaviours comprise presociality and subsociality. There are also many non-social species. Several hypotheses have been made concerning the evolution of these behaviours (e.g. Roth, 1989; Nalepa, 1988). These hypotheses are tested using cladistic phylogenies inferred with morpho-anatomical characters (Grandcolas, 1994, 1996). Comparing phylogenetic patterns with previous evolutionary hypotheses, several points can be raised concerning the evolution of reproductive and social behaviours. Previous hypotheses were biased by *a priori* evolutionary models. Subsociality was hypothesised ancestral to cockroaches because subsocial cockroaches were thought to present many relict behaviours of the common ancestor of the cockroaches and the social group of Termites (Nalepa, 1988). According to phylogeny, subsociality appeared convergently in several cockroaches and was not ancestral to all cockroaches. Features associated to subsociality, such as symbiosis with Protozoa and xylophagy, recently appeared in the same way (Grandcolas & Deleporte, 1996). Reproductive behaviour was supposed to have evolved from more simple systems toward more elaborated ones. The systems which seemed intermediary elaborated were thought to be intermediary evolutionary stages (Roth, 1989). According to phylogeny, reproductive behaviour evolved several times convergently toward ovoviviparity from ancestral oviparity, and once toward viviparity from ovoviviparity. Carrying oothecae and providing them with water in oviparous species is not an intermediary condition leading to ovoviviparity but has evolved independently (Grandcolas, 1996). Using this phylogenetic perspective, cockroaches appear very modern insects contrary to the current opinion which considered them archaic relicts from Palaeozoic period. They do not show many ancestral characters and they have evolved toward very complex reproductive and social behaviours.

ECOGEOGRAPHICAL DISTRIBUTION OF ORTHOPTERA
M.G. Sergeev
Department of General Biology, Novosibirsk State University, Novosibirsk, Russia, and Laboratory of Insect Ecology, Institute for Systematics and Ecology of Animals SO RAN, Novosibirsk, Russia

The spatial approach (including the regional one) allows us to evaluate biogeographical regions for the Palaearctic Orthoptera. Each of them is determined by both geographically and ecologically. From the biological point of view every region is an aggregate of species populations, united by a territory. It may be described as an historical combination of the endemic and widely distributed Orthopteroid species, and also as a specifically arranged aggregate of populations, regularly distributed over local landscapes. These populations form corresponding communities in habitats. The another essential problem is to estimate permeability of different barriers on the various scales. So we can determine the possible and optimal ways for species spreading (migrations, wanderings), colonizing new landscapes and regions, and creating new populations. In this way, we may to understand the problems of a biological diversity of Orthoptera more correctly, because we can evaluate both a taxonomic diversity and diversities of populations and communities too.

01-028

BIOGEOGRAPHY OF THE PALAEARCTIC PAMPHAGIDAE (ORTHOPTERA)

M. La Greca

Dipartimento di Biologia Animale, Università di Catania, Catania, Italy

The Pamphagidae are spread over the whole Africa, the Mediterranean area and the Palearctic Asia. Of the subfamilies, the Eliotropinae are all restricted to the southern Africa and the Porthetinae are essentially living in the southern Africa with 14 genera. The Akicerinae have a markedly disjoined distribution: they are present in the southern Africa (5 endemic genera) and are also spread over western and central Asia with 18 genera and in the Mediterranean lands with 5 genera. The subfamily Pamphaginae is wholly Palearctic. The Pamphagidae most likely differentiated from a Gondwanian stock of Pamphagoidea and originated in the southern Africa in Mid-Cretaceous when the African plate was already separated from the S. American, Indian, Malaysian and Antarctic-Australian plates. The significant presence of Pamphagidae in the Palearctic Region (more than 350 species versus less than 170 Afrotropical species) can be ascribed to two biogeographical events which took place in the Palaeogene when some plate fragments, the terranes, broke off the northern edge of the African plate and, crossing the Tethys, rafted onto the southern edge of Eurasia, carrying there some stocks of Akicerinae and Pamphaginae. A western terrane (Alborana) accreted with the Iberian-Sardinian-Corsican plate, which afterwards broke up and gave rise by vicariance to the 14 genera of Pamphaginae (the whole tribe of Eurypteryphini included) that populated Spain, Sardinia, Sicily and the Maghreb. One or more eastern terranes accreted with the Afghanian-Iranian edge of the Eurasian plate, allowing the evolutionary explosion in Asia of further 21 genera of Pamphaginae and 18 genera of Akicerinae. Another evolutionary explosion of the Akicerinae happened quite likely at the end of Miocene, during the salinity crisis of Mediterranean, when they pushed forwards, both westwards, along the northern and southern Mediterranean coasts, and eastwards to Mongolia and China.

01-030

THE RANGE OF EGG CAPSULE MORPHOLOGY WITHIN THE PHASMATODEA AND ITS RELEVANCE TO THE TAXONOMY OF THE ORDER

J.T. Clark Sellick, V. Scali¹

31 Regent Street, Kettering, Northants UK - 1 Dip. Biologia Evoluzionistica Sperimentale, Università di Bologna, Italy

Within the order Phasmatodea there is a basic egg capsule morphology which defines the order. This shows extensive variation in detailed form.

Some of this is aberration, which can be recognised and excluded from taxonomic considerations. Much is adaptation to egg-laying techniques and egg survival. Nevertheless the range of the egg capsule form both externally and internally is a valuable aid to the classification at sub-ordinal level and below of this group of insects.

In particular this confirms the Timematodea as members of the order and shows some subfamilies such as Necrosiinae to be taxonomically very diverse.

01-029

KARYOTYPICAL PROPERTIES OF THE SHORT-HORN ORTHOPTERANS INSECTS (ORTHOPTERA, CAELIFERA) IN RUSSIA, KAZAKHSTAN, THE CAUCASUS, AND MIDDLE ASIA FAUNA

A. Bugrov

Department of General Biology, Novosibirsk State University, and Institute of Systematics and Ecology of the Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russia

Comparative karyological analysis showed that taxonomic diversity of short-horn orthopterans of the former USSR fauna combines with karyotypical conservatism on the level of large superspecies taxa: Eumastacidae (Gomphomastacinae: $2n=19, 21$; $NF=21-42$), Tetrigidae ($2n=13$; $NF=13$), Arididae ($2n=16, 17, 19, 21, 22, 23$; $NF=21, 23-25, 28$), Pyrgomorphidae ($2n=19$; $NF=19$), and Pamphagidae ($2n=18, 19$; $NF=19$).

On the basis of karyotypes features and patterns of chromosome evolution the scheme of phylogenetic relations of researched groups were made.

01-031

THE ROLE OF VITELLOPHAGES DURING YOLK UTILIZATION IN STICK INSECT EMBRYOS.

A.M. Fausto*, M. Mazzini* and F. Giorgi**

* Department of Environmental Sciences, University of Tuscia, Viterbo, ** Department of Biomedicine, University of Pisa, Italy.

Yolk utilization entails proteolytic degradation of vitellin polypeptides into progressively smaller products. The role played by vitellophages in this process has been investigated by ultrastructural analysis of yolk degradation in the stick insect *Carausius morosus*.

During the first stages of embryogenesis vitellophages invade the yolk fluid mass from the eggs periphery using slender cytoplasmic filopodia. This causes the yolk mass to be gradually engulfed inside the vitellophages and to be partitioned into large intracellular granules. In *C. morosus* the vitellophages originate mainly from a thin layer of stem cells, the so-called yolk cell membrane, interposed between the germ band and the yolk mass. Throughout development, a thin basal lamina separates the yolk cell membrane from the overlying embryo. Later in development, endodermal cells migrate lengthwise along the embryo's axis, gradually replacing the yolk cell membrane.

After yolk sac closure, the intestinal cells start to differentiate. At the posterior end of yolk sac, endodermal cells migrate in clusters spaced out by some intervening extracellular channels. Through these channels the yolk sac lumen becomes continuous with the hemocoel across the basal lamina. As respect to other regions of yolk sac, the vitellophages occupying the posterior end are the first to undergo degradation.

The role of cell-to-yolk and cell-to-cell interactions in the yolk sac are discussed in relation to the process of yolk utilization.

01-032

GENOMIC DNA ANALYSIS OF PARENTAL AND HYBRID *BACILLUS* STICK-INSECTS (PHASMATODEA).

B. Mantovani, F. Tinti.
Dip. Biologia Evoluzionistica Sperimentale, Univ. Bologna, Italy.

Genomic DNAs of the bisexual *B. rossius* and *B. grandii* and of their diploid hybrids *B. rossius-g. grandii*, *B. rossius-g. benazzii* and *B. whitei* (= *B. rossius/grandii grandii*) have been tested for the presence of the highly repetitive DNA family *Bab300* (Mantovani et al., Ins. Mol. Biol. 2:141-147, 1993). Multimeric ladders of the monomer were obtained with *AluI*, *TaqI*, *BglII*, *Clal*, *DraI*, *EcoRI*, *NsiI* and *NdeI* restriction enzymes from the genomic DNAs of *B. grandii* subspecies (*B. g. grandii*, *B. g. benazzii*, *B. g. maretimi*) and of the hybrids, whereas they were not observed in genomic digests of *B. rossius*. Southern blots tested with *B. g. grandii* DIG-probes revealed cross-hybridization with digests of the other *B. grandii* subspecies and of hybrid populations. No signal was found in *B. rossius* digests. *In situ* hybridization showed a pericentromeric localization of the *Bab300* family on all chromosomes of *B. grandii* and on the *grandii* haploset embodied in its hybrids (Tinti and Scali, this Congress). Sequence data support the existence of a unique satDNA family in *B. grandii* subspecies and in their hybrids with *B. rossius*. The sequence homology percentages ranged from 80 to 97%, including *B. atticus* sequences. We therefore propose to re-name this satDNA *Bag320*. Dendrograms obtained with different tree-building methods constantly showed a subspecies clustering pattern for *B. grandii* populations; sequences from hybrid strains clustered with the corresponding parental *B. grandii* subspecies. These data support the existence of two well differentiated species-groups (i.e. *B. atticus-grandii* and *B. rossius*) and reinforce the ascertained phyletic relationships between hybrids and ancestral species; moreover, sequence analyses seem to suggest a different evolutionary rate of satDNA in bisexual and parthenogenetic taxa.

01-034

EGG MATURATION AND DEVELOPMENT IN HEMICLONAL AND CLONAL HYBRIDS OF *BACILLUS* STICK INSECTS

L.P. Pijnacker, O. Marescalchi¹, F. Tinti¹
Dept. of Genetics, University of Groningen, The Netherlands - 1
Dip. di Biologia Evoluzionistica Sperimentale, Università di Bologna, Italia.

Interspecific crosses between *B. rossius* and *B. grandii* produced two hybridogens (*B. rossius-grandii benazzii*, *B. rossius-grandii grandii*), a diploid parthenogen (*B. whitei*) and, by hybridization to a third species (*B. atticus*), a trihybrid triploid parthenogen (*B. lynceorum*). During hybridogenetic oogenesis unassorted parental genomes are segregated and the paternal *grandii* haploset is eliminated, whereas the *rossius* hemiclone is passed to the offspring. Their hybrid structure is renewed each generation through real fertilization of the hemiclonal eggs by host *grandii* males. The oogenetic mechanism of the corresponding clonal hybrid *B. whitei* is similar, only differing in the automictic re-use of the segregated, not degenerating *grandii* haploset; therefore *B. whitei* offspring maintain the maternal hybrid structure. The triploid *B. lynceorum* produces clonal descendants through an apomictic mechanism undergoing two mitotic divisions. Each *Bacillus* hybrid thus realizes a different egg maturation mechanism, but all of them share an intrameiotic DNA extradoubling leading to fourstranded chromosomes which divide mitotically once (in hybridogens and in *B. whitei*) or twice (in *B. lynceorum*). Finally, fertilized eggs of *B. whitei* are able of incorporating an additional *B. grandii* or *B. rossius* genome, with the production of fertile "synthetic" triploids, embodying two *grandii* and one *rossius* genomes or vice versa. Cytological findings provide evidence that in *Bacillus* allodiploids whole genome segregation, elimination or addition occur. Furthermore they suggest that parthenogenesis may have evolved from hybridogenesis and that unisexuals can keep interacting with related bisexual taxa.

01-033

VITELLIN PROCESSING IN OVARIAN FOLLICLES AND IN EMBRYOS OF *CARAUSIUS MOROSUS* (BR.) (PHASMATODEA: LONCHODINAE)

M. Masetti, A. Cecchetti¹, M.T. Locci¹, F. Giorgi¹
Department of Environmental Sciences - 1 Department of Biomedicine
University of Pisa, Italy

Vitellogenins (Vg) are high molecular weight glycoproteins that are transferred from the maternal hemolymph to the oocyte, as vitellins (Vt), during oogenesis. With the onset of embryonic development, Vt are gradually degraded by limited proteolysis to provide raw material for the growing embryo. Vg are synthesized by the fat body, secreted into the maternal hemolymph and specifically endocytosed by the oocyte. In the stick insect *Carausius morosus* transfer through these compartments entails an extensive processing of some Vg polypeptides. Vg processing proceeds *pari passu* with fusion of the yolk granules in the oocyte such that, by the end of vitellogenesis, mature ovarian follicles comprise a unique yolk fluid mass. In this study we have documented the nature and the time course of this vitellogenic protein processing, using specific monoclonal antibodies against Vt polypeptides. Following egg laying, embryos start to develop parthenogenetically. Vitellogenes have already been shown to take part in this process by partitioning the unique yolk fluid mass into a collection of morphologically different yolk granules. Vt are once again processed proteolytically yielding lower molecular weight polypeptides with a stage and time specific appearance. In this study we have documented the pattern of Vt proteolytic degradation and have also identified the peptide fragments that are generated by each Vt polypeptide during embryonic development. In a parallel series of experiments, methacrylate sections of stick insect embryos belonging to different developmental stages were tested by immunostaining using different monoclonal antibodies. The evidence obtained through this procedure shows that yolk granules are differentially stained in relation to the stage of development attained and to the antibody used. The observations carried out in this study suggest a model whereby proteolytic processing of Vg and Vt in stick insects can be functionally correlated with the morphological changes that characterize the yolk granules during vitellogenesis and embryogenesis.

01-035

THE GENUS *SIPYLOIDEA* BRUNNER IN AUSTRALIA (PHASMATODEA: PHYLLIIDAE; NECROSCIINAE)
D. C. F. Rentz,
CSIRO, Division of Entomology, GPO Box 1700, Canberra, A. C. T.

The stick insect genus *Sipyloidea* Brunner von Wattenwyl is represented in Australia by at least 12 taxa most of which are undescribed. Elsewhere the genus is represented in south-east Asia and the Pacific with the type species, *S. sipylus* Westwood, having come from Assam. The species are very similar in overall appearance. Males are winged and capable of flight; females are micropterous and bear small, lanceolate wings that are incapable of flight. The body colour is typically light to dark green; rarely the top of the head and the base of the legs may have an orange tinge. In both sexes the tegmen is a small round pad with a dark brown or black patch dorsally, with or without green spots. The male wing has a light grey-green border with the remainder of the wing pink to purple; the minute female wing is grey or greenish grey.

Australian *Sipyloidea* species are difficult to distinguish morphologically. The genitalia provide the best anatomical characters with the shape of the cercus, vomer and tenth tergite being distinctive among males. Females are almost indistinguishable and with sympatry and parthenogenesis common in the genus, museum specimens of the female sex cannot be determined with certainty.

01-036

IN SITU HYBRIDIZATION OF HIGHLY REPETITIVE DNA IN *BACILLUS* STICK INSECTS: CYTOTAXONOMY AND GENOME EVOLUTION

F. Tinti and V. Scali

Dip. Biologia Evoluzionistica Sperimentale, Univ. Bologna, Italia

Systematic investigations on *Bacillus* stick insects allow the recognition of three species groupings within the genus: a) the *grandii-atticus* group, including the bisexual *B. grandii* and the parthenogenetic *B. atticus*, which share most morphological, chromosomal and allozymic features; b) the monospecific *B. rossius* group, showing a great differentiation from the former; c) the 'hybrid' group, constituted by three different *rossius/grandii* diploid hybrids and by one *atticus/rossius/grandii* allotriploid taxon (Scali et al. 1995, Boll. Zool. 65:59).

Molecular investigations on satellite DNA have been recently carried out on all species of the genus using recombinant DNA techniques, sequencing and fluorescent *in situ* hybridization (FISH). Main achievements are: i) the occurrence of the *Bag320* satDNA family in the genome of *B. atticus*, *B. grandii* and their hybrids and its absence from *B. rossius*. DNA sequences from all investigated taxa were always highly homogeneous, but a clearcut cluster differentiated *B. atticus* from *B. grandii* even using different phylogenetic tree-building methods (Mantovani & Tinti, this congress); ii) the *Bag320* satDNA was always localized in the pericentromeric region of the chromosomes; iii) while in the *B. atticus* haplotype (n=17) only a chromosome subset (13-15) showed the hybridization sites, in *B. grandii* all chromosomes (n=17) had the signal; iv) diploid *rossius/grandii* hybrids (2n=35) constantly showed 17 fluorescent spots, corresponding to the *grandii* haploset; v) in the allotriploid *atticus/rossius/grandii* trihybrid (3n=52), 32-34 chromosomes hybridized, corresponding to the *grandii* and the *atticus* haplosets.

Main achievements of these investigations are the cytomolecular characterization of the karyotypes of all *Bacillus* taxa and the recognition that unequal cross-over mechanisms had to work to quantitatively differentiate the *Bag320* family within *B. atticus*.

01-038

SYSTEMATICS, PHYLOGENY, AND A NATIONAL COLLECTION, II: UTILIZING A NATIONAL COLLECTION FOR SYSTEMATICS RESEARCH, THE LEPIDOPTERISTS OF THE UNITED STATES NATIONAL MUSEUM, 1890-1940

M. Epstein

Department of Entomology, National Museum of Natural History, Smithsonian Institution, Washington, DC, USA

The National Entomological Collection served as the basis for a strong research tradition in Lepidoptera in the U.S. Lepidopterists such as H.G. Dyar, A. Busck, C. Heinrich, W. Schaus, and J.F.G. Clarke both utilized and continued to develop the national collection of Lepidoptera for research in insect systematics and evolution and economic entomology. The close working relationship between entomologists at the United States Department of Agriculture and the United States National Museum allowed the national collection to grow during a period when the museum provided minimal or no staffing. This era was characterized by colorful personalities who engaged in legendary debates with their colleagues within and outside the museum. Issues such as the development of the International Code of Zoological Nomenclature, the admissibility of Huebner's *Tentamen*, and the proposed sale of the Barnes collection united previous adversaries. At the end of this era, Clarke began his career with the USDA. He was later to transfer to the Smithsonian and, through his leadership, found a separate Department of Entomology, increasing the staffing of entomologists at the museum to far beyond previous levels.

01-037

SYSTEMATICS, PHYLOGENY, AND A NATIONAL COLLECTION, I: THE ROLE OF C.V. RILEY, J.H. COMSTOCK, AND L.O. HOWARD IN CREATING A NATIONAL ENTOMOLOGICAL COLLECTION IN THE UNITED STATES

P.M. Henson

Institutional History Division, Smithsonian Institution, Washington, DC, USA

The National Entomological Collection at the National Museum of Natural History, Smithsonian Institution, (formerly the United States National Museum) is the result of the vision of three seminal figures in the history of entomology in the United States: Charles Valentine Riley, John Henry Comstock, and Leland Ossian Howard. Riley established a national entomological research and collecting program at the United States Department of Agriculture. That collection became the core of the National Museum collection. Comstock advocated a national collection for basic systematic and evolutionary research, as well as economic entomology. His student, Howard, synthesized the approaches of Riley and Comstock, as he served simultaneously as Chief of the USDA Bureau of Entomology and Honorary Curator of the Division of Insects at the National Museum. As the Smithsonian celebrates its 150th anniversary in 1996, this session will trace the history of its role in the development of American entomology.

01-039

THE COLLECTION OF TYPHLOCYBINAЕ BY CARLO VIDANO (RHYNCHOTA AUCHENORRHYNCHA)

A. Arzone, A. Alma

Dipartimento di Entomologia e Zoologia applicate all'Ambiente "Carlo Vidano", Università di Torino, Italy

Insect collections have an important role in systematics because they offer a precious material of comparison for the classification of the entomofauna. Collections, even of small entity, but of a high specialization, have a special significance when they are made by entomologists who, besides the locality, consider environment, biotope, host plant, niche, localization on the plant, trophic behaviour, and so on.

In this frame, the collection of European Cicadellidae Typhlocybinae by Carlo Vidano has a noteworthy interest for the specialists of these insects. It comprises about 16,000 specimens of 160 species collected systematically in all Italian regions and desultorily in many European countries, including the types of the 12 species described by Vidano, and is arranged in 55 entomological boxes.

The specimens were collected rarely by means of an entomological net, more frequently with a glass tube on well known herbaceous plants or trees; several of them emerged from nymphs reared in captivity on the host plants. The most part is preserved dry on pointed cards or stored in small plastic tubes. Since the classification of these species is made by means of the analysis of male genitalia, several males of each species are dissected and their anal block and aedeagus are prepared and glued on the same card. The number of the collecting protocol together with locality, altitude, and host plant are reported on cards underneath.

The collection is completed and made precious by the collecting protocols, which are an integrant part of it and are gathered in 5 note books. 974 protocols are written in these books in a chronological order, and concern the captures carried out from 1955 to 1989. For each locality they provide altitude, exposition, date, hour, biotope, vegetal biocenosis, reproduction site, natural enemies, meteorological conditions, insolation, shading, and any element useful to the knowledge of ecological and ethological aspects of the different species.

01-040

NOTES ON THE CONTEMPORARY CLASSIFICATION OF DERMAPTERA

S.SAKAI, Institute of Life Sciences, Daito Bunka University, No.2-26-12, Sendagi, Bunkyo, Tokyo, Japan:113.

The author presents a new revisional classification of Dermaptera and all known species and Fossil species of Dermaptera are listed up until July, 1995. There are 4 suborders, 4 superfamilies, 11 families, 54 subfamilies, 11 groups, 3 tribes, 219 genera, 40 subgenera, 1,951 species, 37 subspecies, 34 varieties and 13 forma of Dermaptera of the world including 55 fossil Dermaptera. Arixeniina: 2 genera and 5 species; Hemimerina: 3 groups, 9 species and 1 variety; Pygidicranoidea: 2 families, 12 subfamilies, 8 groups, 30 genera, 11 subgenera, 361 species, 3 subspecies, 2 varieties and 2 forma; Anisolabidoidea: 2 families, 11 subfamilies, 45 genera, 16 subgenera, 418 species, 10 subspecies, 2 forma and 7 varieties; Apachyoidea: 1 family, 1 subfamily, 2 genera and 15 species; Spongiphoridae: 13 subfamilies, 3 tribes, 42 genera, 504 species, 12 subspecies, 6 varieties, and 4 forma; Chelisochidae: 2 subfamilies, 15 genera, 95 species, 1 subspecies and 1 variety; Forficulidae: 10 subfamilies, 65 genera, 13 subgenera, 486 species, 11 subspecies, 17 varieties and 5 forma; Fossil Dermaptera (excluding Protelytroptera): 7 families, 28 genera and 55 species. In Pygidicranidae, Acrania and Picrania are valid genera. Cranopygia is separated into 3 groups: Cumingi, Marmoricrura and Valida groups. Prolabiscinae is valid subfamily. The genera in Diplatyinae: Haplodiplatys, Paradiplatys, Circodiplatys, Nannopygia, Diplatys; Gonolabina transferred to Esphalmininae. In Forficulinae; Chelidura is separated into 6 subgenera: Chelidura, Borelliola, Burriola, Maraniola, Mesochelidura and Chelidurella.

01-042

DERMAPTERAN CENTRES OF EVOLUTION.

Edward J. Popham, 26 Branch Rd. Mellor, Blackburn, England.

and Seiroku Sakai, Institute of Life Sciences, Daito Bunka University, Tokyo, Japan, 113. The analytical techniques of Newton & Platnick (1981) have been applied to Sakai's phylogenetic trees to deduce the centres of evolution of the main Dermapteran taxa with special reference to their geographical distribution on the land masses before the opening of the Pacific Ocean in the Triassic. The Pygidicranidae, Anisolabidae, Arixeniidae and Labiidae originated in the same equatorial region of the eastern Pacific, whereas the Labiduridae, Apachyidae, Chelisochidae and Forficulidae have common Afro-Indian centres of evolution. The Hemimerina are of African origin. Sakai's classification suggests that his two Infraorders each have the same two widely separated centres of evolution: an anomaly which Popham's (1965, 1983 and 1990) classification of the Order avoids by placing the Anisolabidae, Labiidae and Arixeniidae in one taxon and the Labiduridae, Chelisochidae, Apachyidae and Forficulidae in another. The African Hemimerina were placed in a separate but allied order.

01-041

THE PHYLOGENY OF THE FORFICULINA (DERMAPTERA)

Fabian Haas, Institut für Spezielle Zoologie, Erbertstr. 1, D-07743, Jena, Germany

The phylogeny of the Forficulina (Dermaptera) has been reassessed. Forty-eight species and thirty characters were examined, of which thirteen characters of thorax and wings are described or used for phylogenetic purposes for the first time. The remaining seventeen characters have been extracted from literature. Examination of the thirty characters demonstrates that only twenty-three characters are useful for phylogenetic reconstruction. The characters have been analysed with PAUP 3.1 yielding two equally parsimonious trees. The results suggest an exclusion of the 'Diplatyidae' (themselves paraphyletic) and the Karschiellidae from the Pygidicranidae and support the separation of the Apachyidae from the Labiduridae. A sister-group relationship of the Anisolabidae and Spongiphoridae is not supported. The monophyly of the Eudermaptera is confirmed.

The relationship is:

(Karschiellidae ('Diplatyidae' (Pygidicranidae (Apachyidae (Labiduridae (Anisolabidae (Spongiphoridae (Chelisochidae, Forficulidae)))))))).

The results demonstrate that a re-interpretation of the evolution of the male genitalia is necessary. The last common ancestor of the extant Forficulina had genitalia with two lobes pointing in one direction, with two virgae each. This type of genitalia is found in the Diplatyidae. So, it represents a plesiomorphy and not an autapomorphy as assumed before. As the next stage, one virga in each lobe was reduced, resulting in a situation which is found in the Pygidicranidae. However this is not an autapomorphy for this family. After that, one lobe changed direction, pointing cranially now. It is not a synapomorphic feature of the Apachyidae, Labiduridae and Anisolabidae, as shown by the branching pattern; it is a „stage“ in the evolution. Finally, the number of lobes was reduced to one. This situation is found in the Spongiphoridae, Chelisochidae and Forficulidae and is considered as a synapomorphy for these groups.

01-043

DERMAPTERA AND PROTELYTROPTERA - ONE ORDER?

A.V. GOROCHOV (Zoological Institute, Russian Academy of Sciences, S. Petersburg, 199034)

L.N. ANISYUTKIN (S. Petersburg University, Russia)

S.SAKAI, Institute of Life Sciences, Daito Bunka University, No.2-26-12, Sendagi, Bunkyo, Tokyo, Japan:113.

The orthopteroid orders Orthoptera, Dictyoptera (Blattodea+Mantodea), Plecoptera, Grylloblattida, Phasmoptera have very long and rich history (from Palaeozoic). Sometimes these orders are presented by 2 or more recent stocks diverging from Palaeozoic or Triassic (for example Orthoptera). These stocks we usually consider as suborders or infraorders. Sometimes the orders are presented only by 1 recent stock of the same age (for example Dermaptera). Nevertheless this stock usually also subdivides into suborders and infraorders (inequivalent to the analogous taxa of previous orders as the rate of evolution of different orders of orthopteroids was more or less similar except maybe Isoptera).

Dermaptera sensu stricto (without Archidermaptera and enigmatic Hemimerina) appear from late Jurassic. Their morphological diversity is almost equal to that of the superfamily Grylloidea (from late Triassic or early Jurassic). On the other hand the Permian Protelytroptera is undoubtedly ancestral group for recent earwigs (all peculiarities of skeleton and wing venation confirm this origin). Therefore we propose to consider the Protelytroptera as a suborder of Dermaptera (sensu lato) and to consider the Dermaptera sensu stricto (+Archidermaptera) as other suborder. This conception allows to lower the ranks of other higher taxa of the order. In that case order Dermaptera becomes comparable with other large orders of orthopteroids by age and level of differentiation.

01-044

MIT.DNA, BIOSYSTEMATICS AND EVOLUTIONARY BIOLOGY OF EARWIGS.

T. Wirth, M. Vancassel.

URA-CNRS 1853, Université de
Rennes 1, France.

First attempts of between families comparison of earwig mit. DNA, revealed particular base composition in the order. This new parameter, as well as the genetic distances between different families (Forficulidae, Labiduridae, Carcinophoridae) evolves consistently with the phylogenetical reconstructions established on morphological characters (Popham, 1965; Sakai, 1986).

These phylogenetical relationships also agree with the tropical origin of the order associated with iteroparity and the « apomorphic » status of adaptations to colder climates, leading to semelparity repeatedly observed in alpine and continental conditions.

01-046

BIOCHEMICAL ANALYSIS IN GEOGRAPHICAL VARIATION OF *ANECHURA HARMANDI* (FORFICULIDAE, DERMAPTERA)

TERARA, Kohji and SAKAI, Seiroku (Institute of Life Sciences, Daito Bunka University, Higashimatsuyama, Saitama, Japan 355)

Anechura (Odontopsalis) harmandi (Burr, 1904) had three morphological forms, that is, forma *harmandi*, *lewisi* and *soedaensis*. In Honshu or the Main Island of Japan, there are two types of population, which are *lewisi*- monomorphic populations and *lewisi* & *harmandi*-polymorphics.

Three monomorphic populations and nine polymorphics were electrophoretically compared with each other in three enzymes of Mdh(1 locus), 6Pgdh(1 locus) and G6pdh(2 loci). Nei's distances between populations were summarized by UPGMA. As a result, the monomorphic and polymorphic populations were not distinguished and the difference between them was small except for two populations of monomorphic and polymorphic ones. The two were over subspecies- level distant from the others.

Furthermore, the monomorphic and polymorphic populations were compared with each other by means of random amplified polymorphic DNA-polymerase chain reaction.

01-045

ONE NAME BUT TWO SPECIES: MOLECULAR PHYLOGENY AND BIOGEOGRAPHY OF THE SO CALLED "EUROPEAN EARWIG", *FORFICULA AURICULARIA*.

T. Wirth¹, R. Le Guellec²,
M. Vancassel¹, M. Veuille³.

1, URA-CNRS 1853 and 2, URA-
CNRS 256, Université de Rennes 1, France;
3, Institut d'Ecologie,
Université ParisVI, France.

The discovery of a very distinct reproductive isolation between two populations of *F. auricularia* led to investigation of possible genetic divergence. A fraction of mit. DNA was analysed for fifteen European and North American populations. Results of between populations crosses were confirmed by measurements of genetic distances which indicated the existence of two distinct lines. The *F. auricularia* taxon in fact includes two twin species. Their contemporary distribution reflects their long standing presence in Europe and multiple recent introductions to North America.

01-047

KARYOTYPE ANALYSIS OF A FORFICULID EARWIG, *ANECHURA HARMANDI* (FORFICULIDAE, DERMAPTERA)

HOSHIBA, Hidehiro and SAKAI, Seiroku (Daito Bunka University, Dai-ichi High School, Takashimadaira, Itabashi, Tokyo, Japan 175 and Institute of Life Sciences, Daito Bunka University, Iwadono, Higashi-Matsuyama City, Saitama, Japan 355)

The chromosomes of a Forficulid earwig, *Anechura harmandi* (Burr, 1904) were observed in the male germ cells.

Materials were collected at Okuchichibu, Saitama, Japan on March, 1985. Their testes were dissected out in the 1% sodium citrate solution containing 0.001% colchichin and kept in this solution for 30 min. Preparations were made by lactic acid dissociation, drying technique improved by Hoshiba et al.(1993). Twenty nine cells from five adult males were analyzed. Their chromosome number was $2n=25$.

Although 487 Forficulid species have been recorded, only 11 species of their chromosomes have been studied. Their number of autosome pairs (N^{ap}) are mostly eleven and they are characterized by sex chromosomes polymorphism such as $N^{ap}=11$ with XY (*Anechura bipunctata*, *Apterygida media*, *F. tomis succuderi*, *F. beelzebub*, *F. schlagintweitii*, *F. mikado* and *Forficula auricularia* has XY₁, XY₂), X₁X₂Y (*Pseudochelidura sinuata*) and XY₁Y₂ (*F. auricularia*). The others are the species with $N^{ap}=9$ (XY, *Elaunon bipartitus* and X₁X₂Y, *F. smyrnensis*) and $N^{ap}=7$ (XO, *Allodahlia macropyga*).

The chromosomes of *Anechura harmandi* probably consisted of 22 autosomes and X₁X₂Y. Further chromosome observations on spermatogenesis and female oogonial cells are required to determine the sex chromosomes.

01-048

KARYOTYPE EVOLUTION IN DERMAPTERA

OM P. MITTAL, Department of Zoology, Panjab University, Chandigarh- 160014, India

and

S. SAKAI, Institute of Life Sciences, Daito Bunka University, No.2-26-12, Sendagi, Bunkyo, Tokyo, Japan : 113

Survey of the cytologically known dermapterans reveals that their chromosome numbers vary from $2n=7$ in *Hemimerus bouvieri* to $2n=42$ in an unidentified species of *Anisolabis*, with gaps at certain numbers. In species with $2n=10-20$ two categories of chromosomes exist viz. short rod- and large rod-like. In another group of these insects with $2n=20-30$, moderate-sized chromosomes are met with. However, in forms with $2n=32$ or more, the chromosomes are small rod-like. The co-relation between the numerical decrease of chromosomes and relative increase in their length or vice-versa strongly supports that the karyotype evolution in Dermaptera has taken place either by fusion of the smaller chromosomes or by fission of larger ones, resulting in numerical decrease with increased length or numerical increase with decreased length of chromosomes, respectively. It seems, this type of evolution has been facilitated by the presence of diffused or at least non-localised nature of the kinetochore in these insects, since it renders the chromosome fragment or fused chromosome easy to function as a autonomous whole, as is true of other primitive insects like aphids and bugs etc.

01-050

A PREVIEW OF THE CATALOGUE OF THE DERMAPTERA OF SPAIN

L. HERRERA-MESA. Department of Zoology & Ecology, University of Navarra, 31080 Pamplona, Spain..

The latest studies made on the Fauna of Dermaptera in peninsular Spain and the Balearic Islands comprise 22 species including such endemic as *Eulithinus analis* (Rambur), *Mesochelidura bolivari* (Dubrony), *Pseudochelidura sinuata* (La Fresnaye) and *Chelidura pyrenaica* (Gené).

Canary Island Fauna include the following endemic species: *Anataelia canariensis* Bolívar, *Anataelia lavicola* Martín and Oromí, *Anataelia troglobia* Martín and Oromí, *Anisolabis maxima* (Brullé), *Perirhytus endetelus* (Woll.) and the ten species of the genus *Guanchia* (*G. bandamaensis* Morales, *G. cabreræ* (Bolívar) *G. canariensis* (Burr), *G. fernandesi* Morales, *G. gomerensis* Morales, *G. guanchia* (Heller), *G. storai* (Chopard), *G. tenerifensis* Morales, *G. transversa* Brindle and *G. uxoris* Heller. The Catalogue of the Dermaptera of Spain comprises 37 species (3 Pygidicranidae, 7 Carcinophoridae, 2 Labiduridae, 1 Labiidae and 24 Forficulidae), 2 varieties and 2 forms.

01-049

Notes on four new species of Dermaptera from China.

Zhou, Wen-bao (Zhejiang Museum of Natural History, Hangzhou, 310012) and Sakai, Seiroku (Institute of Life Sciences, Daito Bunka University, No.2-26-12, Sendagi, Bunkyo, Tokyo, Japan 113)

4 new species: *Forficula bimaculata* Zhou et Sakai, Figs.1-2; *Forficula ruiliensis* Zhou et Sakai, Figs.3-4; *Anechura sakaii* Zhou, Fig.5; *Auchenomus huai* Zhou et Sakai, Figs.6-8.

Forficula bimaculata Zhou et Sakai: Male, Length of body with forceps: 16 mm. Tegmina brownish red with a yellow oval spot at the shoulder, Genitalia: virga forming an angle at the junction with the basal vesicle. Holotype & Paratype male: Zhejiang Mus., 20.VI.1987, Fengangshan, Zhejiang.

Forficula ruiliensis Zhou et Sakai: Body length: Male: 8.5-10.5, Female: 11.0 mm; Forceps: Male: 2.8-3.0, Female: 2.9 mm. Zhejiang Mus., 5.VI.1983, Yunnan: Ruili

Anechura sakaii Zhou: Body length: Male: 8.5 mm; Forceps: 4.0 mm. Although Sakai (1995: Dermapt. Cat., 26: 5951, 27: 6946, 7051) synonymized with *Anechura pilosa* Ma et Chen (1992), Now this species is valid species. Male: Holotype: Zhejiang Mus., 10.VII.1986. Zhejiang: Longquan, Fengyangshan.

Auchenomus huai Zhou et Sakai: Body length: Male 10.0, Forceps 2.0; Female: 12.0, Forceps: 3.8 mm. Holotype, Allotype: Zhejiang Mus., 12.XI.1982, Hainan: Jianfengling

01-051

RESEARCHES ON PHILIPPINE DERMAPTERA

S. SAKAI, P. A. JAVIER and C. D. ABELLON; Institute of Life Sciences, Daito Bunka University, No. 2-26-12 Sendagi, Bunkyo, Tokyo, Japan: 113; National Crop Protection Center, WPLB, College, Laguna; RDC-JKL, #12 General Macundo St., Baguio City, Philippines, respectively.

The present record of Philippine Dermaptera consists of 145 species belonging to two suborders, 18 subfamilies and 46 genera.

Some of the dominant species of earwigs that play a major role in the biological control of the Asian corn borer, *Ostrinia furnacalis* were *Euborellia annulata*, *E. philippinensis*, *Proreus simulans*, *Nala lividipes* and *Labiduria riparia* in decreasing order. The life cycle of these five earwig predators were discussed. The predators were reared in the laboratory using larvae and pupae of red flour beetle, *Tribolium castaneum*.

The dispersal of adult *E. annulata* was studied by release and recapture of marked individuals. The percentage recovery was higher during the initial sampling and then decreased in the succeeding samplings. The large percentage recovery was observed at a distance of three to six m from the release point. As the distance traveled by the earwig from the release point increased, the recovery decreased. The initial maximum distance traveled by the earwig after release was six m and then increased to 9.5 m after 14 days. Based on simple linear regression analysis, the dispersal of earwig consistently increased with time after release. The dispersal pattern was found to be clumped.

The selectivity to the earwig of eight insecticides (recommended against corn borer) of different chemical structures were evaluated. The adverse effects of the insecticides to the earwig decreased as follows: monocrotophos > deltamethrin > cypermethrin > chlorpyrifos ethyl + BPNC > carbofuran > methomyl = carbaryl > endosulfan. Based on the selectivity ratio, carbofuran and cypermethrin are the most selective insecticides to the earwig.

01-052

NEW Records of New Guinean Dermaptera,

SAKAI,Seiroku,Institute of Life Sciences,Daito Bunka University,No.2-26-12,Sendagi,Bunkyo,Tokyo,Japan,113. and Zhang,Xiao-chun',Institute of Zoology,A'camia Chinica, Beijing,19 Zhongguancun Lu,Haidian,Beijing 100080,China.
22 species of Dermaptera from New Guinea as the result of the expedition of New Guinea by A.Riedel,1990-1993.
Adiathetus papuaensis Sakai(1995:Dermapt.Cat.30:9303)
Chelisochinae,Chelisochidae,Irian Jaya 1100-1300 m and *Spongovostox riedeli* Sakai(1995;Dermapt.Cat.30:9306)
Spongiphorinae,Spongiphoridae,Irian Jaya,1700-1750 m are described.

Systematic records of New Guinean Dermaptera:
Anisolabididae:*Euborellia plebeja*,*Gonolabis javana*,Apachy-
dae:*Apachyus becaarii*,Spongiphoridae:*Nesogaster aculeatus*,
Auchenomus blumi,*Auchenomus setulosus*,*Chaetospania fuscata*
fuscata,*Paralabella fruhstorferi*,*Paraspania brunneri*,*Irdex*
ernstmayri,*Spongovostox riedeli*,Chelisochidae:*Chelisoches*

cordax excelsior,*Hypurgus biroii*,*Pterygida burgursi*,*Ptery-*
gida poultoni. *Adiathetus papuaensis* Sakai(1995)

01-054

A PHYLOGENETIC CLASSIFICATION OF THE APACHYIDAE (DERMAPTERA) AND BIOGEOGRAPHIC ANALYSIS
G.CASSIS

The Apachyidae are defined as a monophyletic family of Dermaptera on the basis of characters of the mouthparts, abdomen and genitalia. The family contains three genera and fifteen species. A new genus is erected for the annectant species, *Dendroiketes novaeguineae* Boeseman. A new species of *Apachyus* Audinet-Serville is described from the Northern Territory of Australia and the peculiar morphology of *Apachyus peterseni* Borelli is described in detail. A cladistic analysis of the species will be presented with emphasis on the biogeography of this palaetropical group. The area relationships will be discussed in relation to current models of Indo-Pacific biogeography (Schuh and Stonedahl, 1986). The systematic position of the Apachyidae will be discussed in view of the current polemics of their relationships (Popham, 1965; Steinmann, 1975; Haas, 1996).

01-053

CONTRIBUTION TO THE STUDY OF EARWIG(INSECTA,DERMAPTERA) FROM GUINÉ-BISSAU.
A.Bivar de Sousa,Sociedade Portuguesa de Entomologia, Praceta Fernando Pessoa,3-9°Esq.Carnaxide,P-2795 Linda a Velha Portigal and Seiroku Sakai,Daito Bunka University, No.2-26-12,Sendagi,Bunkyo,Tokyo,Japan 113.

The Guine-Bissau(Formerly Portuguese Guiné)Dermaptera were firstly studied by Borelli(1907)based on Leonardo Fea collected in this territory between 1898 and 1900.In that work a total of 14 species were recorded. Some up-dates concerning taxonomic nomenclature or synonymies and based always in Borelli(op.cit.)work were published by Rehn(1924], Hincks(1951,1955) and Brindle(1973,1978).

This paper gives faunistic and ecological informations about the Dermaptera fauna of Guiné-Bissau,based on field research during the following periods:16,November-7,December 1983,14,June-5 July,1992 and 25 June-17 July,1995.

From this field research 17 species were identified and among them 10 are recorded for the first time for Guiné-Bissau being 2 of them new species (*Anisolabis guineensis* n.sp.Bivar de Sousa and *Paradiplatys serranoi* n.sp.Bivar de Sousa). With this study a total of 24 species are reported for this country.

01-055

ON THE PHYLOGENY OF ADEPHAGA (COLEOPTERA), WITH SPECIAL EMPHASIS ON TRACHYPACHIDAE

R. G. Beutel

Institut für spezielle Zoologie und Evolutionsbiologie, Friedrich-Schiller-Universität Jena, 07743 Jena, Germany

Edges of rivers are a likely habitat of the stem-species of Adephaga. The ability to survive in an environment which is flooded periodically was an important requirement for early representatives of the suborder. Aquatic habits were acquired three times independently in the evolutionary history of Adephaga. This hypothesis is based upon the phylogenetic interrelationships of the families and the different adaptations of the three aquatic monophyla. Gyrinidae were the first group to enter the aquatic environment. A sistergroup relationship between this taxon and the remaining Adephaga is well supported by larval and adult features. A second and third invasion was accomplished by Haliplidae and Dytiscoidea respectively. Trachypachidae, which are the sistergroup of Dytiscoidea or Carabidae, were widespread in the early Mesozoic. The monophyly of the genera *Trachypachus* and *Systolosoma* is well supported by apomorphic character states of larvae and adults. Trachypachidae were reduced to a small relict group in the Cretaceous. Extroral digestion and correlated structural features are more advanced in carabid larvae than in those of Trachypachidae. The enormous expansion of Carabidae during the late Mesozoic was probably closely connected with the angiosperm revolution. A correlation between characteristic structural transformations of the pro- and mesothorax and the appearance of leaf litter is likely. Similar apomorphic conditions may have evolved several times independently within Carabidae.

01-056

INFERRING PHYLOGENETIC RELATIONSHIPS WITHIN CARABIDAE FROM CHARACTERS OF THE FEMALE REPRODUCTIVE TRACT

J.K. Liebherr, K.W. Will

Department of Entomology, Cornell University, Ithaca, NY, USA

The female reproductive tract of Carabidae--spermatheca and associated glands, bursa copulatrix, and ovipositor--offer a rich array of characters that are stable or associable via transformation series within lower-level lineages, yet strikingly divergent at the tribal to subfamilial ranks. In order to illustrate the utility of this character system for phylogenetic inference, representatives of 69 of the 75 tribes of Carabidae *sensu lato*, recognized by Erwin's classification, were examined and used as exemplars in a parsimony based cladistic analysis. Characters of abdominal configuration, delineated by Deuve, were also included in the analysis. Where possible, a variety of cladistically basal and derived taxa were examined within each tribe. This approach, by its nature, may result in hypotheses that render tribal taxa para- or polyphyletic, however, as the study's aim is to provide a broad sketch of carabid relationships useful for more intensive studies, such a shortcoming is considered justified. Groups traditionally difficult to place form one focus of the study; Rhysodini, Brachinini, and Pseudomorphini. *Omoglymmius* of Rhysodini exhibits derived states of a vaginal apophysis and subsegmented gonocoxae, suggesting affinities to Metriini+Ozaenini+Paussini. Brachinini possess segmented gonocoxae and a spermatheca with apical reservoir and appendiculate spermathecal gland, consistent with placement in Anisochaeta, though adult characters argue against placement in the Harpalidae of Deuve. Pseudomorphini exhibit a spermatheca with appendiculate gland, triangular laterotergites, and falciform gonocoxae, suggesting placement near Pogonini and Patrobini, consistent with Erwin's placement--based on male aedeagal and larval characters--as a lineage basal to Pterostichini.

01-058

MORPHOFUNCTIONAL AND ECOLOGICAL FEATURES IN CARABID LARVAE: A CONTRIBUTION TO DISTINGUISH BETWEEN AFFINITY AND CONVERGENCE.

T. Zetto, J. Marano, P. Brandmayr

Dipartimento di Ecologia, Università della Calabria, 87036 Arcavacata di Rende, Italy.

Larval stages of Carabid Beetles show a wider morphological variation than the adults, but the most characters they "offer" are normally used only as character states for reconstructing phylogeny. The authors tried to investigate morphofunctional features of about 60 genera, starting from Sharova's "morpho-ecological types" and including a re-examination of recent literature on head-muscle morphology and preying behaviour. Morphometry of mandibles, shape and size of head capsule and adductory muscles, integumental sclerification and morphology of urogomphi have been correlated to: phytophagous or predatory habits, type of prey (molluscs, earthworms, collembolans, etc.), behaviour, overall relationship to soil features and soil layer, life on vegetation, parasitoid lifestyle.

The most important selection pressures determining morphofunctional adaptation of Carabid larvae seem to be i) soil and ecosystem type, that influence especially body shape and urogomphi; ii) prey selection, that influences mostly the form of the head and of mandibles. A possible evolutionary "pathway" of larval functional morphology is sketched, evidencing some key-selection pressures. The validity of some of the basic morphotypes recognized by Sharova has been confirmed.

Pattern and occurrence of morphofunctional characters in some of the commonly accepted phyletic trees of Carabidae is discussed.

01-057

PHYLOGENETIC INVESTIGATION OF CARABIDAE USING LARVAL CHARACTERS

E. Arndt, University of Leipzig, Institute of Zoology, Leipzig, Germany

Morphological characters of larvae of 44 tribes of Carabidae as well as representatives of Trachypachidae (both genera), Rhysodidae, all families of Hydradephaga, Micromalthidae (Archostemata), and 6 families of Polyphaga are examined. Larval characters suggest the monophyly of Carabidae (excluding Rhysodidae), Trachypachidae and Dytiscoidea. The presence of egg bursters in first instar is a synapomorphy of these taxa. The Carabidae are monophyletic and characterized by 3 possible autapomorphies in larval stage. Larvae of Rhysodidae are extremely derived and lack the autapomorphies of Carabidae.

The position of tiger beetles is not to clarify with larval characters at present. The recent classification of tiger beetles (with two subgroups and 5 tribes) is not confirmed by larval characters. Only a part of Megacephalini are the sister group of the rest of cicindelid taxa. Metriitae and Paussitae form a monophyletic unit, which has separated very early from the rest of Carabidae.

Larval characters support the monophyly of subfamily Harpalinae (*sensu* Erwin) including all "higher" carabids. The larval characters found in Platynini may come close to the ground plan of the Harpalini. A monophyletic unit which comprises all members of the Pterostichini, Morionini, Callistini, Oodini, Licinini, Panagaeini, Peleciini, Harpalini, Cnemacanthini, and Zabrinini is characterized by a significant synapomorphy: a membranous band in the middle of stipes. The monophyly of Truncatipennia (excluding Brachinitae) is not confirmed by larval characters.

01-059

An overview of karyotypic evolution and phylogeny of carabid beetles.

J. Serrano, J. Galián. Departamento de Biología Animal. Facultad de Veterinaria. Apto. 4021. 30071 Murcia (Spain).

More than eight hundred species of Caraboidea have been karyotypically studied, mostly from the Holarctic fauna. Data usually refer to basic characters such as chromosome number (diploid or haploid) and type of sex chromosomes. Other characters such as chromosome bands, presence of satellites, or estimation of genome size, have been determined only for a few species. The usefulness of karyotypic data for phylogeny depends also on the karyotypic pattern of each taxa, some of which are rather conservative whereas others show a high dynamism.

The family as a whole shows the highest variation in chromosome number within the Coleoptera, making it difficult to assess the ancestral diploid number. However, it is clear that the suborder Adephaga is characterised by chromosome numbers higher than $2n = 18 + Xyp$ karyotype predominating within the other suborders of Coleoptera. In addition, the typical "parachute" y chromosome of the order is not present within the Adephaga.

A variety of situations is found within between lower taxa, as some show a constancy in karyotypic characters (e.g., genera *Carabus*, *Bembidion*, *Chlaenius*), whereas others show marked differences even between closely related species (e.g., genera *Ceroglossus*, *Nebria*, *Scarites*, *Poecilus*, *Brachinus*).

The main conclusions concerning supraspecific taxa are: 1. Carabini is an homogeneous taxa including both *Carabus* and *Calosoma*, and is related to Ceroglossini; 2. Cicindelids are characterised by multiple sex chromosomes although Megacephalini may have experimented a reversion to simple systems; 3. Scaritini, Clivinini and Dyschiriini are different tribes according to their chromosome number and size; 4. The supertribe Trechitae is characterised by an achiasmatic meiosis, although each tribe shows its own karyotypic formula; 5. Tribes of Pterostichitae share the same karyotypic pattern of high numerical variation around $2n = 37$; the subtribes of Zabrinini show opposite karyotypic patterns; 6. Ditomina is a subtribe supported by high chromosome numbers ($2n = 45-69$) with regard to other subtribes of Harpalini; 7. Within the supertribe Lebiitae a suprageneric taxon joining *Microlestes*, *Lionychus* and *Syntomus* is supported by present data; 8. Brachinina and Aptinina seems to share an ancestral karyotype of $2n = 32$, whereas Pheropsophina is characterised by a different number, $2n = 35-36$; these subtribes shows the same predominant pattern towards low chromosome numbers.

Other phylogenetic inferences concern relationships between related genera or species; some sibling species show marked differences in karyotypic features.

01-060

PHYLOGENY OF CARABID TRIBES AS INFERRED FROM MOLECULAR SEQUENCE DATA (COLEOPTERA)

D.R. Maddison, M.D. Baker, and K.A. Ober
Department of Entomology, University of Arizona,
Tucson, AZ 85721 U.S.A.

The phylogenetic relationships of carabid tribes has been investigated using DNA sequences. This report of work-in-progress focuses on some enigmatic groups within carabids:

- (1) are brachinines related to the ozaenine-paussine complex, or are they members of Harpalinae?
- (2) is *Gehringia* one of the basal stocks of carabids or is it a psydrite?
- (3) to what are *Omophron*, pseudomorphines, and morionines related?

Some questions relating to the composition of Carabidae (including the placement of trachypachids) are also addressed with molecular data.

01-061

KARYOTYPIC EVOLUTION AND MITOCHONDRIAL DNA PHYLOGENY OF THE GROUND BEETLE GENUS *SCARITES* (COLEOPTERA: CARABIDAE) FROM THE IBERIAN PENINSULA

J. Galian^{1,2}, P. De la Rúa¹, J. Serrano¹, G. M. Hewitt² and C. Juan²

¹ Departamento de Biología Animal, Universidad de Murcia, Apdo. 4021, 30071, Murcia, Spain. ² Population Biology Sector, School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ, U.K.

The chromosomal number, the sex-determining mechanism and the chromosomal localization of ribosomal DNA loci have been determined in the seven Iberian species of the genus *Scarites*. The chromosome number varies between $2n=38+X$ in *S. planus*, and $2n=60+X$, in *S. laevigatus*. Male sex chromosomes are XXY in *S. buparius* and *S. occidentalis*, and XO in the other species. Fluorescence in situ hybridization using a PCR amplified ribosomal probe obtained from *S. occidentalis*, indicates that rDNA clusters have an autosomal position varying from four to six sites in all species except for *S. planus*, in which there are four sites in two autosomal pairs and one site in the single X chromosome. In addition, it has been sequenced a 280 bp fragment of the cytochrome oxidase I gene, and analyzed by maximum parsimony and sequence distance methods. These results suggest the following conclusions: 1. The species of the subgenus *Scallophorites*, *S. occidentalis* and *S. buparius*, are clustered together both by karyotypic and molecular results; 2. The species of the subgenus *Scarites*, *S. eurytus* and *S. hespericus*, are related by karyotypic features, and the mtDNA sequence of *S. eurytus* relates this species to the subgenus *Parallelomorphus*; 3. The two species of the subgenus *Parallelomorphus*, *S. laevigatus* and *S. terricola* are also grouped by both kind of data; 4. The single species of the subgenus *Distichus*, *S. planus*, is the most distantly related to the other Iberian *Scarites* on the basis of the presence of rDNA sites in the X chromosome, and the presence of an A+T rich intergenic spacer of 121 bp between the stop codon of the COI gene and the tRNA^{leu}, which is not present in the other species of the genus. These differences support the proposed ranking of *Distichus* as a separate genus, based on morphological characters.

01-062

THE PHYLOGENETIC RELATIONSHIPS OF CICINDELOIDS: EVIDENCE FROM DNA SEQUENCES

Alfried P. Vogler and David L. Pearson¹

Department of Entomology, The Natural History Museum, London, SW7 5BD, and Department of Biology, Silwood Park, Imperial College, Ascot, Berkshire, SL5 7PY, U.K. - ¹ Dept. of Zoology, Arizona State University, Tempe, AZ 85287, U.S.A.

The Cicindelidae are a group of some 2000 described adephagan species which are generally placed in the vicinity of the Carabidae. Competing hypotheses group the cicindelids either within the Carabidae (near the hiletines, the loricarines, or the carabines) or outside of the Carabidae (as the sister taxon or as a clade separate from the Carabidae retaining many of the ancestral features of early Adephaga). We are using DNA sequences to address the relationships of cicindeloids to each other and to other adephagan groups. Both nuclear and mitochondrial rDNA sequences indicate that cicindelids are very different from other caraboids, and no clear synapomorphies with the major tribes of the Carabidae could be found. The molecular data provided a well supported phylogeny for most of the major groups of cicindelids. Unequivocal evidence against the traditional division of the family into two subfamily (Cicindelinae and Collyrinae) was obtained. Taxa in the tribes Omini and Mantichorini are basal for the group whereas the Collyrinae are embedded within the Megacephalini of previous authors. The genus *Cicindela* (s. l.) is the most derived group of the family. The phylogenetic hypothesis for the Cicindelidae will be discussed with respect to shifts in ecological parameters during the evolution of the lineage.

01-063

WHERE DO THE RHYSODINES FIT IN ?

Ross T. Bell

Department of Biology, University of Vermont
Burlington, Vermont 05405-0086, U.S.A.

Rhysodine beetles, like the vast majority of Geadephaga belong to the "Carabidae clausae", characterized by closed anterior coxal cavities. This is not a simple character, but involves major changes in several structures, including the development of a septum between left and right cavities, a vertical column posterior to the coxa, the elongation of the ventral posterior angle of the propleuron to form a postcoxal bar, and the modification of the tip of the bar and its reception into a pit in the column. It is correlated with elongation of the mesosternum, development of a constriction in it anterior to the middle coxae, loss of its median carina, and development of a peg-and-socket median articulation between mesosternum and metasternum. These common features strongly suggest that "Carabidae clausae" is a monophyletic group, and that Rhysodini, as well as Cicindelini, are members of it.

Most of the "Clausae" belong to the "Limbata Lobata", characterized by conjunct middle coxal cavities and a lobe of the metepimeron overlapping the base of the first abdominal sternum laterally. Rhysodines are excluded from this group, as are Cicindelini, Loricarini, Elaphrini and a few other tribes. Rhysodini have the most in common with Scaritini, including an elongate pedunculate mesothorax, front tibiae with processes extending beyond tarsal articulations, similarly shaped repugnatorial glands, similar disc-like, somewhat asymmetrical ventral articulation of the anterior coxae, and similar placement of some prothoracic muscles. These are enough to suggest a common ancestry of Scaritini and Rhysodini.

01-064

PHYLOGENETIC RELATIONSHIPS AMONG "BASAL GRADE" CARABID LINEAGES (COLEOPTERA: CARABIDAE)

D. H. Kavanaugh

Department of Entomology, California Academy of Sciences, Golden Gate Park, San Francisco, California, U.S.A. 94118

This report of research-in-progress on the phylogenetic relationships of basal grade carabid beetles centers on taxa of supertribe Nebriitae, including the Opisthiini, Notiophilini, Notiokasiini, Pelophilini, and Nebriini. Results of computer-assisted cladistic analyses of 370 adult external and internal genitalic morphological features suggest a sister group relationship between Notiophilini and Notiokasiini and between a clade comprising these two taxa and the Opisthiini. In turn, this three-taxon clade is the sister group of the Nebriini (excluding *Pelophila*), and tribe Pelophilini (genus *Pelophila*) is the sister group of a clade including all four other nebriite tribes. Relationships of this most inclusive clade to the Cicindini, Loricerini, and other basal-grade tribes are also discussed.

01-066

CLADISTIC RELATIONSHIPS OF THE TRIBE BROSCINI (COLEOPTERA)

S. Roig-Juñent
Instituto Argentino de Investigaciones de Zonas Áridas (IAIZA), Mendoza, Argentina.

Broschini is a tribe of Carabidae with 255 species distributed in 35 genera. All Broschini are temperate species, occurring around the world both north and south of the tropics.

The tribe Broschini presents no apotypic state; to check its monophyly the cladistic analysis is developed with tribes representatives of the different subfamilies of Carabidae. The characters considered are those proposed for higher classification in Carabidae. Considered taxa correspond to 14 tribes included in different supertribes, and five Broschini genera. The family Trachypachidae was chosen as the outgroup of the whole family Carabidae, following Kavanaugh (1986) and Erwin (1985), who suggested that *Trachypachus* is the sister group of the remaining Carabidae. Character transformations are polarized accordingly to outgroup. The cladistic analysis yielded 16 cladograms. All of them show that the Stylifera (sensu Jeannel) conforms a monophyletic group, where Apotomini, Melaenini and the Broschini genera constitute an unresolved polytomy. The successive weighting procedure yielded three cladograms which show Broschini as a monophyletic (but polythetic) group, as the sister group of Melaenini plus Apotomini, and the relationships between the others tribes is similar to those proposed by Erwin (1985). Other groups considered to be related to Broschini, as Elaphrini, appears in this analysis among the most distantly related taxa in terms of nodal separation of Broschini. Goulet (1983) proposed a close relationship between the tribes Broschini and Elaphrini, since both share the sclerites X and Y in the internal sac. However this structure might be homologous to these found in Melaenini, Paussini (rod of Darlington, 1950), Omophronini (basal piece of Lindroth, 1961b), and the basal stylets of endophallus present in *Schizogenius* (Whitehead, 1972). If this structure is distributed in many tribes, it could be a plesiomorphic structure lost in different tribes. This result is congruent with Erwin's (1985) point of view, that the Elaphrini might be related to Migadopini, not with Broschini. He based his idea because Elaphrini has two larval claws, while Broschini has one.

A second cladistic analysis, using 75 characters, 82 Broschini taxa, and Melaenini and Apotomini as sister groups yielded one cladogram using successive weighting procedure. Four main generic groups are suggested as subtribes. The value of several characters are discussed with reference to Broschini classification.

01-065

CONFLICTS IN PHYLOGENETIC RELATIONSHIPS AND DISPERSAL HISTORY OF CARABITAE (COLEOPTERA, CARABIDAE).

F. Prueser & D. Mossakowski

Institute of Ecology and Evolutionary Biology, University, Bremen, Germany

The tribes of the Carabidae are distributed in a characteristic manner. In the southern hemisphere the Ceroglossini (*Ceroglossus*) are restricted to southwestern South America, the Pamborini to southeastern Australia (*Pamborus*) and New Zealand (*Maori-pamborus*). The Cychrini and the genus *Carabus* s. l. are holarctic. Only *Calosoma* s. l. is distributed world wide.

The Carabidae quite clearly form a monophyletic group, but the relationships of their tribes are questionable: the tree established by Moore (1966) postulates a close relationship of Cychrini and Pamborini and the dispersal processes postulated by Erwin (1979) are based on it.

We analysed a set of morphological characters of adults and larvae which also gives some evidence to support alternative hypotheses concerning the southern tribes.

In addition, we sequenced different genes of the mitochondrial DNA of these taxa. These data were used for a re-analysis of the phylogenetic relationships of the Carabidae tribes as well as for an estimate of their divergence times. Based on these data, we present alternative interpretations of the dispersal processes.

Using the transition/transversion rate of base substitutions of the species under study and of other insects from the literature, the Carabidae split into the extant tribes in a period later than the pangaean, therefore, the spread of the tribes must have occurred independently.

01-067

A PRELIMINARY SURVEY OF THE CLASSIFICATION OF THE PSYDRINAE (COLEOPTERA: CARABIDAE)

M. Baehr

Zoologische Staatssammlung, München, Germany

Psydriinae constitute a very heterogeneous assemblage, both in external and genitalic morphology. Psydriinae as a whole or one of their tribes are believed to represent a group very close to the stem-group from which one of the major branchings within Carabidae arose. The relationships of the tribes of Psydriinae are tracked using the cladistic method sensu Hennig. Except for Psydrini and Melisoderini the monophyly of the tribes can be demonstrated. The monophyly of Psydriinae as a whole is uncertain, because Psydrini are so primitive that even closer relationship of Patrobinae with the remaining 5 tribes of Psydriinae cannot be excluded. The latter form a monophyletic group that splits into the monophylum Tropidopterini-Melisoderini-Amblytelini, whereas the relations of Mecyclothoracini and Meonidini are still uncertain. It is controversial whether Tropidopterini and Melisoderini or Melisoderini and Amblytelini form a further monophylum. Psydrini are certainly the most primitive tribe while Amblytelini are most evolved. Amblytelini and several species groups of Mecyclothoracini have adopted an arboreal or semi-arboreal way of life, and they have also crossed the borders of the wet forests of antarctic origin. Psydriinae (Psydrini excluded!) may have originated in the former Gondwanaland and belong to the "younger antarctic element" in the faunas of Australia and South America. Due to their primitiveness and their occurrence in the Holarctic Psydrini may have originated considerably earlier.

01-068

THE ENIGMATIC TRIBE HELLUODINI: BIOGEOGRAPHY, BIOLOGY AND SYSTEMATICS (COLEOPTERA: CARABIDAE)

B.P. Moore
CSIRO, Division of Entomology, Canberra, Australia

The Helluodini form a small but distinct group that is primarily Oriental in distribution, but with southern extensions to New Guinea and tropical Australia. Little has been published concerning the biology of its members but species of the predominant genus *Pogonoglossus* Chaudoir are known to be subcortical predators. Larvae now attributed to this genus provide further evidence in support of separate tribal status for the group.

01-070

EVOLUTION AT THE EQUATOR: ARBOREAL AND ALTICOLOUS BEETLES AND THEIR TAXON PULSES (COLEOPTERA: CARABIDAE)

Terry L. Erwin - National Museum of Natural History, Smithsonian Institution, Washington, D.C.

ABSTRACT - The neotropical carabid genera *Agra* (Lebiini - Calleidina) and *Batesiana* (Bembidiini-Xystosomina) contain more than 2,100 species, the former with 2,000+ and the latter with ca. 100. One monophyletic lineage of each, the *arrowi* group of *Agra* and the *parainsularis* group of *Batesiana*, was selected for phylogenetic analysis to underpin a biogeographic study pertaining to the Amazon Basin and its mountainous southeastern and western flanks. Both groups arose and radiated from the basin, subsequently invading Central and/or Middle America and the Andean highlands, as well as the South Atlantic Forest. The fact that such major radiation occurred within the basin at the species level in two unrelated significant clades forces us to look for evolutionary driving forces that act relatively quickly and at a fine geographic resolution in order to account for the megadiversity found there today. What are the possibilities? Of those discussed in this paper, the one with the least study is the latest to be introduced - the long term cyclic impact of El Niño on both the forest and the populations of organisms using that forest. Will drought and subsequent fires resulting from hypothesized El Niño events be extensive enough to isolate forest patches, as previously suggested for the pleistocene forest refugia? Will these isolated forests exist long enough for vicariant speciation? How do populations of insects respond to drought ridden tropical forests even when these don't burn? What are the effects of shorter cycles on these same populations, for example, the 4 year El Niño cycle? Is there a connection between cyclic abundance highs and lows and dispersal that might lead to a founder effect across isolated forest patches? Does tropical lowland drought force taxa in higher elevations that act as refugia and a path of no return? These are but a few of the questions raised by newly aquired data and a bold new suggestion - massive Amazonian fires? Is the current activity of humans there *deja vu*?

01-069

PHYLOGENY AND ZOOGEOGRAPHY OF CALLEIDINA (COLEOPTERA: CARABIDAE: LEBIINI) : A PRELIMINARY SURVEY

A.Casale
Università di Sassari, Istituto di Zoologia, Sassari, Italy

Calleidina are a large assemblage of genera and species of Carabidae Lebiini distributed in all continents, with their highest diversity in intertropical areas. Most of them are specialized arboreal beetles, tied to foliage in forest canopies. No recent revision of the group is available to make evident the phylogenetical relationships among taxa - many of which undescribed - from the different parts of the world. In the present contribution, preliminary results of a revision of the former genus *Calleida* Dejean, 1825 (*Callida* Auctorum, in the widest sense) are given. Particularly, two main questions have been posed at the present time: 1) If Calleidina, in the sense of the authors, are a monophyletic unit; and : 2) If the genera and subgenera into which *Calleida* has been split are monophyletic groups. On the base of a cladistic analysis of several characters, it is possible to establish the limits and the systematic position of Calleidina among other subtribes of Lebiini. Furthermore, it seems clear that some supraspecific taxa, proposed or re-defined by different authors, are polyphyletical or paraphyletical assemblages, needing a complete revision. Previous and new characters, and their polarity based on outgroup comparison (including Demetriina, Peliocypina, and Agrina), are discussed, in the light of possible transformation series and convergence of features in specialized arboreal Carabid beetles. Some distribution patterns are examined. Relationships among groups of species or subgenera from Africa, Madagascar and S.E.Asia, became clear. Less evident, but highly probabilistic, seem to be the affinities among some Afrotropical and Neotropical *Stenocallida* and *Calleida*, respectively. The origin of some lineages dispersed to Middle America and the West Indies have also been pointed out.

01-071

LABOULBENIALES (ASCOMYCETES) AND SYSTEMATICS OF THEIR CARABID HOSTS (COLEOPTERA: CARABIDAE)

A. Vigna Taglianti, W. Rossi¹
Dipartimento di Biologia Animale e dell'Uomo, Università di Roma "La Sapienza", Italy - ¹ Dipartimento di Scienze Ambientali, Università dell'Aquila, Italy.

Laboulbeniales are parasitic fungi on living arthropods, mostly insects. They are strictly adapted to parasitic life, as reflected in their peculiar morphology, in the very limited damage caused to their hosts, and in their high host specificity. The latter feature, which is sometimes overemphasised, can, however, provide useful clues in understanding the evolution of their hosts, especially when the systematics of the parasites is reliable. For instance, the same *Dimeromyces* species parasitizes both Afro-Malgascian and Mediterranean Reicheina indicative of a close relationships. Moreover, historical geographical patterns of the different species-groups belonging to the *Duvalius* genus in the Mediterranean area has been successfully reconstructed by analysing their associated Laboulbeniales. Phylogenetic relationships amongst different groups can be drawn by matching hypotheses with data on parasites. *Mexisphodrus* is parasitized by the same Laboulbeniales of the Platynini (not by those of the Sphodrini); the Australian genus *Mecyclothorax* (presently included in the Psydrini) bears fungi similar to those of the Trechini; true relationships of several holarctic species of the "old" *Pterostichus* genus now placed within different tribes or subtribes are witnessed by the different species of associated *Laboulbenia*. Higher ranking is currently under investigation and is providing some interesting data. For instance, the tribe Agonicini seems to merit a place close to the Psydrini; Odacanthinae and Hexagoninae bear similar fungi. Laboulbeniales also seem to support the affinities between Paussinae (*Pseudozena*) and Brachinininae (*Pheropsophus*) as suggested by biochemical studies, somewhat in contrast with morphological data.

01-072

PHENOLIC DIVERSITY IN UNGALLED, SINGLE GALLED AND MULTIGALLED STEMS OF COTTON INDUCED BY THE COTTON STEM WEEVIL, *PEMPHERULUS AFFINIS* FST. (COLEOPTERA: CURCULIONIDAE)

T.N. Ananthakrishnan, D.S. Prakash

Entomology Research Institute, Loyola College, Madras - 600 034, India.

The cotton stem weevil, *Pempherulus affinis* Fst. was found to induce two types of stem galls viz. single and multiple stem galls on cotton, *Gossypium hirsutum* (Cultivars-LRA, SUVIN, MCU-5) and the weed host plant *Sida acuta*. The present study explains the quantitative changes in total phenols, OD phenols, tannins and gossypol among different host plants as well as different levels of infestation. Results revealed that the stems of cotton cultivar LRA and *Sida acuta* showed lesser levels of all the secondary plant metabolites, whereas between different levels of infestation, multigalled stems recorded maximum amounts of these allelochemicals. Individual phenols also showed a differential distribution among different host plants as well as different types of galls. In addition, pyrogallol was found to be the major phenol of single galled stem, whereas gentisic acid and gallic acids were the major phenolic acids recorded in multigalled stems.

01-074

PLANT-HERBIVORE INTERACTIONS AND ANTENNAL MORPHOLOGY STUDIES OF THE BLACKCURRANT LEAF MIDGE *DASINEURA TETENSI* (DIPTERA, CECIDOMYIIDAE). D.J. Crook¹, A.N.E. Birch², R. Brennan², J.A.T. Woodford², A.J. Mordue¹ (Luntz).

¹ Department of Zoology, University of Aberdeen, Aberdeen, U.K.,
² Scottish Crop Research Institute, Invergowrie, Dundee, U.K.

The Blackcurrant Leaf Midge (*Dasineura tetensi*) in recent years has become a major pest of blackcurrant (*Ribes nigrum* L.) throughout the world. Larval feeding causes severe distortion of young leaves and affects plant fitness. Several sources of resistance to *D. tetensi* have been identified in different *Ribes* cultivars but little is known of the mechanisms. During this project the effects of cultivar type on the behaviour of *D. tetensi* will be investigated in both the laboratory and field and the plant-herbivore interactions of the cultivars and midge will be determined.

Investigations carried out using scanning and transmission electron microscopy on the antennae of *D. tetensi* have shown that males and females share the following five types of sensillum: sensilla chaetica, sensilla trichodea, sensilla basiconica, circumfila and terminal sensory pegs. The morphology of each sensillum type is discussed in detail.

Oviposition preference has been studied on resistant and susceptible cultivars in both the laboratory and field. Both linear-track and Pettersson olfactometers along with electroantennogram recordings (EAG's) are being used to establish behavioural and electrophysiological differences elicited in the adults when exposed to both resistant and susceptible *Ribes* cultivar leaf volatiles.

01-073

OPPOSITE EFFECTS OF PLANT STRESS ON DIFFERENT LIFE-STAGES OF A GALL-MAKING APHID

Christer Björkman

Department of Entomology, Swedish University of Agricultural Sciences, P.O. Box 7044, S-750 07 Uppsala, Sweden

The impact of plant stress on the performance and occurrence of gall-making aphids (Homoptera: Adelgidae) was investigated by estimating the size and density of *Sacchiphantes abietis* galls on experimentally stressed Norway spruce trees. Stands of spruce trees were treated so as to create a gradient of tree 'vitalities'. Hence, trees were exposed to different combinations of water and nutrient treatments and comprised a control and the following five treatments: drought, irrigation, ammonium sulphate addition, nitrogen-free fertilization and optimum fertilization with irrigation.

The density of galls was higher on drought-stressed trees than on all other treatments in the second year of the experiment. Possible mechanisms behind this positive 'all or nothing'-type of effect of drought on the aphids are discussed. The proportion of trees with galls did not differ among treatments.

Results on the size of galls and indirect measurements of the fecundity of stem-mothers suggested that stress influences these two parameters oppositely. The positive correlation between spruce growth and gall growth supports the Plant Vigour hypothesis, whereas the negative correlation between spruce growth and number of cells per gall (an indirect measure of stem-mother fecundity) supports the Plant Stress hypothesis. However, these relationships could only be discerned when gall parameters were correlated to the growth potential of the attacked shoot and not on the stand level.

01-075

THE SPERM ULTRASTRUCTURE OF DIPTERAN CECIDOMYIIDAE

R. Dallai, P. Lupetti, F. Frati, B.M. Mamaev¹, B.A. Afzelius²
Dipartimento di Biologia Evolutiva, Università di Siena, Siena, Italia - ¹ Department of Ecology and Forestry, All-Russia Qualification Institute for Forestry Specialists, Pushkino, Moscow Region, Russia - ² Department of Ultrastructure Research, Wenner-Gren Institut, Stockholm University, Stockholm, Sweden

Spermatozoa in Cecidomyiidae lack acrosome and accessory tubules. In other respects and in particular with respect to the flagellar axoneme they display a unique diversity. In Porricondylineae the plesiomorphic genus *Diallactes* (Diallactini) shows an almost conventional 9+2 axoneme, while a 9+3 axoneme is shared by all the other tribes except for Winnertzini which exhibit a 9+0 pattern.

In Lestremiinae there are spermatozoa with a 9+0 axoneme (*Peromyia*, *Bryomyia*, *Heterogenella*), those with 10 (*Xylopriona*, *Polyardis* and *Micromya*) or 20 (*Anaretella*) microtubular doublets arranged in a circle, or also axonemes made of antiparallel spirals of doublets (*Lestremia*).

Cecidomyiinae have several supertribes that can be distinguished by their axonemal models. In Cecidomyiidi the sperm axoneme consists of single rows of doublets; in Asphondyliidi of double, parallel spirals of doublets; in Lasiopteridi of a 9+0 surrounded by singlet microtubules. *Contarinia* and related genera among Cecidomyiidi and *Rhizomyia* among Lasiopteridi have sperm axonemes with microtubular doublets devoid of dynein arms and housed in scalloped plasma membrane; it is suggested to place them in a separate group. Stomatosematidi is a paraphyletic assemblage with *Didactylomyia* and *Stomatosema* showing different axonemes.

01-076

A GENERIC REVISION OF THE LASIOPTERINI OF THE WORLD (DIPTERA: CECIDOMYIIDAE: LASIOPTERIDI)

R.J. Gagné

Systematic Entomology Laboratory, U.S. Department of Agriculture, Washington, DC, USA

The 270 species of known Lasiopterini are distributed among fewer than 15 genera, all but *Lasioptera* restricted by plant host preference and defined by shared, derived characters. *Lasioptera*, containing more than half the species, remains an omnibus genus, although it includes some evidently monophyletic species groups that are restricted by region and host.

01-078

RECENT TAXONOMIC RESEARCH ON THE AFRICAN RICE GALL MIDGE, *ORSEOLIA ORYZIVORA* HARRIS & GAGNÉ

K M Harris

Research Associate, International Institute of Entomology, London, UK

Orseolia oryzivora Harris & Gagné has become a major pest of rice in West Africa during the past decade at a time when rice production has been intensified to meet local needs. A research project initiated by the West Africa Rice Development Association in collaboration with the CAB International Institutes of Biological Control (IIBC) and Entomology (IIE) has included taxonomic studies of *Orseolia* species on cultivated and wild rices and on other host plants. Results of these studies are reported and compared with results of earlier work by Gagné on the Asian rice gall midge, *Orseolia oryzae* (Wood-Mason), and other *Orseolia* species in the Oriental region.

01-077

INDUCED NEAR-IMMUNE RESISTANCE IN WILLOW PROMOTES RAPID LOCAL ADAPTATION IN A GALL MIDGE.

C. Glynn and S. Larsson

Department of Entomology

Swedish University of Agricultural Sciences

S-750 07 Uppsala, Sweden

Certain genotypes of *Salix viminalis* display an immediate and near-immune resistance in response gall initiation attempts by the leaf-roller gall midge, *Dasineura marginemtorquens*. In monoclonal plantations of resistant willows midge population numbers are initially very low but increase dramatically within a few years. We suggest that frequencies of virulent midges are low initially and increase in response to strong selection by the resistant willow. Several aspects of *D. marginemtorquens* life history fill requirements conducive for rapid host adaptation: it is monophagous and has 3-4 generations each season, adults are short lived, mating and oviposition occur on the plant from which larvae developed, mating is non random since midges from resistant plants have a longer developmental time, they seldom encounter mates from susceptible plants.

01-079

FIRST RESULTS OF THE REVISION OF THE LESTREMIINAE FROM THE HOLARCTIC REGION (DIPTERA: CECIDOMYIIDAE)

M. Jaschhof

Zoologisches Institut und Museum der Ernst-Moritz-Arndt-Universität Greifswald, Germany

By using the method of comparative morphology of imaginal characters the lestremiin species described from the Holarctic Region are revised in their entirety for the first time. Since Meigen, in 1818, 462 species in 65 genera were described belonging to the Lestremiinae.

So far as accessible the type material formed the basis for this study, completed by further material from all main lestremiin collectiones including about 3000 specimens of 120 species collected by the author in recent years. Further refinement in investigating morphological characters (particularly concerning the male genitalia and the arrangement of bristles) and another valuation of variability and the occurrence of aberrations (as a result of technical manipulations) proved to be keys for numerous changes at the level of species. Around 50% of the Nearctic species occur in the Palaearctic, too, and the large majority of species inhabits a wide range within the Palaearctic Region (causing double descriptions in former and recent times). Including the description of about 35 species new to science (mainly belonging to *Apriomus* and *Peromyia*) we may assume 280 known valid species in 40 genera of Lestremiinae. Contrasting with these changes, the system of taxa at supraspecific level (genera and tribes) seems to be more constant in relation to the existing ideas, also considering our poor knowledge from other faunas. A phylogenetic classification of the Lestremiinae is proposed at the final stage of the revision.

01-080

NOTES ON THE TAXONOMY AND DISTRIBUTION OF THE
GALL-MIDGES OF THE GENUS *KARSCHOMYIA* FELT
(DIPTERA, CECIDOMYIIDAE)

M.G.Krivosheina

A.N.Severtzov Institute of Ecology and Evolution, Russian Academy
of Sciences, 33 Leninsky Prospekt, 117071 Moscow, Russia

The Revision of the materials on the genus *Karschomyia* Felt from Russia discovered some new objectives. Mamaev (1969) synonymized the genera *Karschomyia* Felt, 1911 and *Plesiobremia* Kieffer, 1912. Gagne (1972) reported that the genus *Hiastatus* Marikovsky, 1956 is the junior synonym of the genus *Karschomyia* Felt. In our opinion there is one distinct character - the absence of the lobe on the gonostylus in *Hiastatus* species - which must be considered at least as subgeneric. So I separate 2 subgenera: *Karschomyia* Felt (= *Plesiobremia* Kieffer) and *Hiastatus* Marikovskij. It is possible that in future the genus *Hiastatus* Marikovskij will be restored as valid genus. The revision besides several new species increased the number of gall-midges with Holarctic distribution. They are *K.viburni* Felt, 1907 (= *K.aceri* Mamaev, 1960, syn.nov.), *K.caulicola* Cog., 1895 (= *K.concinna* Marik., 1956, syn.nov.) and *K.hemispherica* Kov. et Mam., 1966 (= *K.insolita* Gagne, 1973, syn.nov.)

01-082

THE SPECIES CONCEPTION IN FREE DEVELOPING
GALL MIDGES

B.M. Mamaev

All-Russian Institute of Continuous Education in Forestry-
1412200, Pushkino, Moscow region, Russia

The identification of free developing gall midges mainly depends upon morphological characters of male postabdomen, investigated under light microscope. It is the first, the simplest stage of taxonomic investigation. When investigators cannot distinguish similar species they usually list them as synonyms. In the future these synonyms are not taken into consideration. The second stage of taxonomic investigation preferably evaluates all morphological and biological characters and also apply conceptions of vicarious specie, sibling species etc. A number of free developing gall midges are very similar as males, but well distinguishable as females and larvae. Externally very similar species of *Miastor* can be distinguished according to their life-cycle. Indistinguishable males of similar species may be distinguished according to different sperm ultrastructure.

Externally very similar species from different geographic isolated provinces belong to different so-called vicarious species. The origin of these species is the result of genetic isolation of populations. Most of similar Palaearctic and Nearctic gall midges seem to be vicarious species.

The species conception of free developing gall midges has to be co-ordinated with general species conception in biology, including morphological (all stages of development), ultramorphological, biological, zoogeographic and genetic criterions.

01-081

A PHYLOGENETIC ANALYSIS OF HIGHER-LEVEL GALL
WASP RELATIONSHIPS

J. Liljeblad & F. Ronquist

Department of Entomology, Swedish Museum of Natural
History, Stockholm, Sweden

A phylogenetic analysis is made based on morphological characters of adults. The study comprises thirtyseven cynipid species from thirtyone genera representing all six currently acknowledged tribes. From the paraphyletic, and thus problematic, tribe Aylacini nineteen of the twentyone known genera are included. This is the most comprehensive analysis of gall wasp relationships conducted thus far. The results support the monophyly of Synergini and Cynipini as well as that of a larger group consisting of the cynipids making galls on woody rosids, viz. Eschatocerini, Rhoditini, Pediaspidini and Cynipini. There is also strong support for placing *Himalocynips*, suggested to belong to a separate subfamily, in Pediaspidini together with *Pediaspis*. Furthermore, the results suggest a possible division of Cynipidae in three monophyletic groups. One group consisting of Synergini and four genera from Aylacini, a second (the sistergroup of the first) of only Aylacini genera and a third of the remaining six genera together with the aforementioned group of gallmakers on woody rosids. Taxonomic implications of the results are discussed.

01-083

GALL SITE PREFERENCE AND INTRASPECIFIC
COMPETITION OF *NEOTHORACAPHIS YANONIS*
(HOMOPTERA: APHIDIDAE)

P. O. Ngakan, J. Yukawa

Laboratory of Entomology, Faculty of Agriculture,
Kagoshima University, Kagoshima-Shi, Japan.

Some recent studies on galling aphids have put the preference-performance hypothesis in doubt. Our study of a gall aphid *Neothoracaphis yanonis* demonstrated that the stem mothers produce galls more abundantly on the leaves at lower positions on a shoot, and on the basal intermediate part of a leaf blade. On this leaf position and leaf part, aphids produced larger galls, containing more abundant alates. This result suggests that the aphid have evolved to synchronize with the opening of leaves at lower positions, but the leaf part was preferentially chosen. Thus, our observations support the preference-performance hypothesis which assumes that aphid selects the best habitat.

As gall density increased, gall size declined, the percentage of indehiscent galls increased, and the relative abundance of upper-type galls increased. The density effect resulted in promoting the dispersal of stem mothers and reducing the fitness of aphids which located on less favorable sites.

01-084

FACTORS INFLUENCING LOCAL DIFFERENCES IN THE POPULATION DENSITY OF THE CRYPTOMERIA BARK MIDGE, *RESSELIELLA ODAI* (I.) (DIPTERA:CECIDOMYIIDAE)

I. Okochi

Insect Management Laboratory, Forestry and Forest Products Research Institute, Kukizaki Ibaraki, Japan

The cryptomeria bark midge, *Resseliella odai*, is a pest of the Japanese cedar, *Cryptomeria japonica*, an important tree species for silviculture in Japan. The relationship between stand situation and midge density was analyzed. Altitude was the most important factor. Midge density increased slightly at elevations below ca. 800m in altitude, and densities were remarkably high in stands above this altitude. The increment of humidity and the decrement of temperature with elevation may partially explain this change, but the changes in these meteorological factors were linear, in contrast to the change in midge densities. Severely attacked trees in high elevation stands showed unusual tree trunk form because bark was almost completely removed by the bark midge and fungi. This may make further attack by the midge easier, and may explain the high midge density at high elevations. To test this hypothesis, two experiments were done.

01-086

PHYLOGENETIC PATTERNS IN THE EVOLUTION OF THE GALL WASP - HOST PLANT ASSOCIATION (HYM.: CYNIPIDAE)

F. Ronquist, J. Liljeblad¹

Department of Zoology, Uppsala University, Uppsala, Sweden -
¹ Department of Entomology, Swedish Museum of Natural History, Stockholm, Sweden

The early evolution of the gall wasp-host plant association was reconstructed by mapping biological data on recent hypotheses of higher-level cynipid and cynipoid relationships. The results indicate that gall wasps evolved from parasitoids of insect larvae living inside plant tissue, possibly inside seed capsules of *Papaver*. The gall was originally manifested externally solely by a simple but distinct swelling of surrounding plant tissue. The familiar, complex and species-specific galls on oaks and roses evolved later in a single, evolutionarily successful cynipid lineage galling woody rosids.

Most lineages of gall wasps remained associated with herbaceous hosts; woody hosts were apparently colonized only three times during the evolution of cynipids. The herbaceous hosts primarily belong to a narrow spectrum of genera within the families Asteraceae, Papaveraceae and Lamiaceae. The history of the association is characterized by periods of constraint interrupted by major shifts between apparently unrelated host plants. There are striking parallelisms in these host plant shifts; alternative hypotheses to explain this pattern are discussed.

The inquiline apparently originated from gall wasps inducing galls on *Potentilla*. When one lineage of these gall wasps shifted host plant to *Rubus* bushes, which were also galled by other, closely related cynipids, they lost their gall-inducing capacity and became inquiline.

01-085

THE GALL MIDGE *LASIOPTERA ARUNDINIS* HAS EVOLVED STRUCTURAL AND BEHAVIORAL FEATURES TO DISSEMINATE ITS FUNGAL SYMBIONT

O. Rohfritsch, Institut de Biologie Moléculaire des Plantes,

12, rue du Général Zimmer, 67084 Strasbourg Cedex, France

Lasioptera arundinis attacks the common reed stem. With the help of its associated fungus, the first instar larva penetrates into the stem and gains access to the vascular tissues of the host plant. The larva feeds both on the reed stem and on the fungal hyphae. The imago and the first larval stage have adapted structures to collect and to carry the fungus. The imago has evolved a specific preovipositional behavior which allows fungal spore collection and dissemination. Spores and small fragments of hyphae, collected along the upper internodes of the reed stem, are harvested in two pockets localized at the terminal part of the ovipositor. During oviposition, a canal leads the spores to the oviduct. Eggs and fungal spores are deposited together on the reed stem. These very specialized structures will be described.

01-087

SYSTEMIC ANATOMY OBSERVATIONS ON CECIDOMYIIDAE (DIPTERA, NEMATOCERA)

M. Solinas

Istituto di Entomologia Agraria, Università di Perugia, Italy

A preliminary study on the gross anatomy of larval central nervous system, larval and imaginal digestive systems, and adult (both female and male) reproductive systems has been carried out with few gall midge species but looking forward to a more comprehensive study in the Cecidomyiidae family. The larval central nervous system has been confirmed to be formed by a relatively big cerebrum, located in the prothorax, a well developed suboesophageal ganglion, and a relatively short ventral nerve cord with 10 ganglia (last ganglion elongate and apparently compound). The alimentary canal has been investigated in *Mayetiola destructor* Say adults, in *Mycodiplosis tremulae* Kieff. larvae, and both in larvae and adults of *Monarthropalpus buxi* Lab. and *Aphidoletes aphidimyza* Rond. where it shows strong similarity between larval and imaginal mesenteron (always posteriorly blind) whereas both stomodaeum and proctodaeum undergo important modifications during metamorphosis. The reproductive system has been studied in *M. destructor*, *A. aphidimyza* and *M. buxi*, among which it shows a very similar structure (both in females and males). Possible physiological, behavioural, or ecological interpretations are discussed.

01-088

ROLE OF LARVAL GREGARIOUSNESS OF THE PINE NEEDLE GALL MIDGE, *THECODIPLOSIS JAPONENSIS* UCHIDA ET INOUE (DIPTERA: CECIDOMYIIDAE), IN ITS REPRODUCTIVE SUCCESS AND POPULATION CHANGES.

K. Sone
Faculty of Agriculture, Kagoshima University, Kagoshima, Japan

The larval gregariousness of the pine needle gall midge, *Thecodiplosis japonensis* Uchida et Inoue (Diptera: Cecidomyiidae), did not cause the death of larvae in the gall but decreased the size of larvae. The decline in the larval size did not cause a simple decline in the number of eggs deposited per female. Females that emerged from medium size larvae deposited many more eggs than those from large and small larvae. The number of emerged adults per gall was expected to increase with the number of larvae per gall. The calculated number of eggs deposited per gall increased with an increase in the number of larvae per gall from one to five, but not when the number of larvae per gall was more than six. The oviposition pattern, depositing eight eggs on average per pair of needles, and the larval gregarious in galls may offer the midge the maximum reproductive success. On the other hand, when the population is in an outbreak phase, larval gregariousness may cause a drastic decline in the population density.

01-090

CUTICULAR STRUCTURES ON THE HEAD OF THE MATURE LARVA OF CECIDOMYIIDAE (DIPTERA), ADAPTIVE AND SYSTEMATIC ASPECTS

R. Tastás-Duque
Department of Zoology, University of Stockholm, Stockholm, Sweden

The external structure of the head capsule of last instar larva of 23 species of gall midges representing different taxonomic groups and varying larval habits was examined using Scanning Electron Microscopy (SEM). Some structural characters, as for example the length of the antenna, were found to be adaptations to the life in the gall, or to a predacious or sporo-mycophagous life. The examinations also demonstrate synapomorphies for tribes, sub tribes, and genera. Evolution appears to have occurred mainly towards reductions of external parts of the sensilla.

01-089

TAXONOMY OF CERTAIN PALEARCTIC *DASINEURA* AND *JAAPIELLA* SPECIES (OLIGOTROPHINI, CECIDOMYIIDAE) DEVELOPING IN HEADS OF ASTERACEAE

E. Sylvén, B. Lindberg¹
Department of Entomology, Swedish Museum of Natural History, Stockholm, Sweden - ¹ LENS-TECH AB, Skellefteå, Sweden

Many of the gall midges referred to here are characterised by a pronounced morphological conformity. However, not least on the basis of morphometric analyses a good understanding of the taxonomical relationships was obtained. The measurement values were corrected for allometric deviations, according to a method representing a further development of a procedure previously tested for taxonomical purposes in gall midges. Oligotrophine specimens originating from larvae collected in heads of plants distributed among eight genera of Asteraceae were taxonomically studied. No apparent galls are produced by these midges. Adults, pupae, and larvae were analysed. Several *Jaapiella*, and two *Dasineura* species are represented. Most species are new to science. Host plant relationships of the species are discussed.

01-091

RECOLONIZATION OF THE KRAKATAU ISLANDS, INDONESIA BY GALLING INSECTS AND MITES

J. Yukawa, T. Partomihardjo¹
Laboratory of Entomology, Faculty of Agriculture, Kagoshima University, Kagoshima-Shi, Japan - ¹ Research and Development Center for Biology (LIPI), Bogor, Indonesia

The Krakatau Islands are situated in the Sunda Strait between Java and Sumatra, Indonesia and consist of 4 islets, namely Rakata, Panjang, Sertung, and Anak Krakatau. As is well known, the former three islets were almost certainly completely sterilized by the world-famous large eruption in 1883, and the last islet emerged in 1930s by submarine volcanic activities. We visited the islands and the vicinities 16 times from 1981 to 1994 to study the succession of plants and their associated insects and mites, particularly those responsible for galls on various plant species. The galler's fauna of the Krakataus was similar to that of Java rather than to Sumatra and showed a distinct faunistic disharmony. Species number was still increasing, and turnover events were recognized during the course of plant succession. These results were compared with those for other herbivorous and predacious insects.

01-092

PHYLOGENETICS OF STREBLIDAE (DIPTERA) WITH A PRELIMINARY ASSESSMENT OF THEIR COEVOLUTION WITH BATS (CHIROPTERA).

J. William O. Ballard, Bruce D. Patterson and Rupert L. Wenzel
Department of Zoology, The Field Museum, Chicago, USA.

The primary goal of this research program is to advance understanding of the ecology and genetics of host-ectoparasite interactions. Here we outline a program of morphological and biochemical studies of batflies (Diptera: Streblidae) that is based on the alcohol collection at the Field Museum that is unparalleled in size, diverse in taxonomy and provenience, and thoroughly documented as to host and other faunal associates. The collection includes most valid species of streblids, as well as numerous undescribed forms. A total of 16,293 vials of batflies have been curated, labeled and organized into a fully relational database. The database is intended to serve at least three functions: (1) to rapidly identify and locate batfly specimens needed in either morphological or molecular analyses; (2) to process, label, and install incoming material; and (3) to serve as an enlarging cross-tabulation of parasite occurrences (and co-occurrences) on bats across the Neotropics. This latter feature of the database will be useful in identifying and framing coevolutionary questions.

01-094

MOLECULAR SYSTEMATICS AND POPULATION GENETICS IN POLYNESIAN BLACK FLIES: PRELIMINARY MITOCHONDRIAL DNA DATA.

J.E. Conn and K.B. O'Brien
Department of Biology, University of Vermont,
Burlington, VT, USA.

Hypothesis 1: Testing the monophyly of the subgenus *Inseliellum*.

We sequenced 340 base pairs (about 45%) of the mitochondrial DNA (mtDNA) *COII* gene of three species of Polynesian black flies in the subgenus *Inseliellum*. We chose *Simulium oviceps*, *S. cataractarum* and *S. tahitiense* because they are in distinctive clades in a phylogenetic hypothesis based on morphological characters, and they are morphologically diverged, at least in the larval stage. Samples were collected from 2 different river systems in Tahiti-iti and 3 in Tahiti. We found a low level of intraspecific variation (less than 5%). The three consensus sequences differed by 27 base pairs or approximately 8% divergence. Divergence at this level will likely provide sufficient informative characters for reconstructing the subgenus *Inseliellum* when all available species are used.

Hypothesis 2: Habitat specialist species display restricted intraspecific gene flow while generalist species have greater gene flow.

We chose three species pairs that are distributed only on the islands of Moorea and Tahiti. One of each pair is a specialist, found exclusively on cascade faces, while the second is a generalist, found in various types of streams. *Simulium cataractarum* and *S. oviceps*, the first species pair examined, display differences in restriction fragment lengths for mtDNA genes *ND4* and *ND5*.

01-093

A PHYLOGENETIC INTERPRETATION OF PALAEARCTIC SPECIES OF *HILARA* AND THE TRIBE HILARINI (DIPTERA: EMPIDIDAE)

M. Chvála

Department of Zoology, Charles University,
Praha, Czech Republic

A first attempt of cladistic analysis of relationships between major groups of Palaearctic *Hilara* and for their natural classification.

The archaic lineage with a full set of plesiomorphic characters that belong to the ground plan of the genus *Hilara* is apparently represented by species classified in the *Hilara flavipes*-group. This complex of species is thought to be closest to the ancestral forms of the tribe Hilarini. On the contrary, the species of the *Hilara maura*-complex are considered to be the most specialized forms within the Palaearctic *Hilara*, characterized by the apomorphic loss of sensory bristles on body and legs.

The evolution of epigamic behaviour from the organized male synorchestia in biotopes distant from waters (in holoptic males of the *Hilara flavipes*-group) to unorganized, large, obviously emergence zonal swarms above water of the *Hilara maura*-complex (both sexes dichoptic), clearly follows the presumed phylogeny of *Hilara*.

Cladograms are presented showing the relationship between major groups of Palaearctic *Hilara*, and the monophyly of Hilarini is supported by ground plan characters.

01-095

THE HIGHER-LEVEL PHYLOGENY OF EREMONEURA (DIPTERA: BRACHYCERA)

J.M. Cumming, B.J. Sinclair¹

Centre for Land and Biological Resources Research, Agriculture and Agri-Food Canada, Research Branch, CEF, Ottawa, Ontario, Canada -
¹ Department of Environmental Biology, University of Guelph, Guelph, Ontario, Canada

Phylogenetic relationships of the major lineages of Eremoneura (Empidoidea + Cyclorrhapha) are examined. The monophyly of the Empidoidea and its sister group relationship with Cyclorrhapha is reconfirmed, despite the discovery of postgonite precursors in the ground plan of the male genitalia of Empidoidea.

The relationships of the major subgroups of Empidoidea are re-evaluated. The polyphyletic subfamily "Oreogetoninae" is broken into several groups and the relationships of the remaining subfamilies are presented in light of these component subgroups. Based on characters of the male and female genitalia, the Brachystomatinae is considered the sister group of the Trichopezinae + Ceratomerinae lineage and this clade is hypothesized to be the sister group of the "Microphorinae" + Dolichopodidae lineage. Together these five subfamilies are tentatively considered the sister group of all remaining Empidoidea based on the apomorphic loss of acanthopores in the latter lineage. This latter assemblage contains several well-defined component lineages including the Clinocerinae, the Empidinae + Hemerodromiinae, the "Ocydromiinae" + Tachydromiinae + Hybotinae clade and its sister group the Atelestinae, and various genera and generic groups previously placed in the "Oreogetoninae" or a few other subfamilies.

The relationships of the basal lineages of the Cyclorrhapha are also examined. Opetiidae and Platypetidae are considered to be the basal lineages in the infraorder, whereas the Lonchopteridae is hypothesized to be the sister group of the Phoroidea (Ironomyiidae + Sciadoceridae + Phoridae). The Syrphoidea (Syrphidae + Pipunculidae) is considered the sister group of the Schizophora. Relationships within the diverse schizophoran lineage remain largely unresolved.

01-096

USING DROSOPHILA AS A PARADIGM IN SYSTEMATICS; AT THE INTERFACE OF DEVELOPMENT AND EVOLUTION.
R. DeSalle, Department of Entomology, American Museum of Natural History, New York, NY 10024.

Drosophila melanogaster is one of the premier model organisms of the twentieth century. Its use in genetics, evolution, development and molecular biology has greatly advanced our understanding of these fields. More recent work on many of the closely related taxa to *D. melanogaster* in the dipteran family Drosophilidae has expanded systematic vistas too. This talk will discuss the family Drosophilidae as a paradigm for enhancing our understanding of systematic analyses and principles. The first topic for discussion in the talk will concern an examination of how molecular analyses have enhanced systematic studies of the group. In particular, the role of molecular sequence characters and their combination with morphological characters will be discussed. The second part of the talk will focus on the relatively new field of comparative molecular biology and developmental biology. The use of modern molecular techniques such as in situ hybridization and dissection of developmental processes can add to the number and types of characters that can be used in Drosophilidae systematics.

01-098

PHYLOGENETIC ANALYSIS OF CHARACTERS OF THE FEMALE REPRODUCTIVE TRACT OF ACALYPTRATE SCHIZOPHORA (DIPTERA)

M. Kotrba

Department of Entomology, National Museum of Natural History, Washington, DC USA

"The phylogenetic classification of the Acalyptratae is probably the most difficult chapter in the systematics of Diptera (McAlpine 1989)." It has been repeatedly suggested that for further resolution the morphology of the internal female reproductive tract needs to be investigated comparatively (Hennig 1973, McAlpine 1989).

An extensive collection of data on a number of characters of the internal female reproductive tract is presented and cladistically analyzed. Such characters are the number and form of the spermathecae, the occurrence and organization of a ventral receptacle, and the occurrence of other evaginations or sclerotized structures in the vagina. All 64 (McAlpine 1989) families of acalyptrate Schizophora are included. The plesiomorphic spermathecal number of Schizophora is thought to be 3. However, in the prevailing majority of acalyptrate families, genera with 2 spermathecae occur. In 34 families 2 is the only known condition. It can be assumed that 2 spermathecae are plesiomorphic not only for the Ephydroidea but also for Opomyzoidea and Carnoidea. The presence of a ventral receptacle is established in 56 families, but it is probably present in all of them. Multi-chambered forms occur in at least 21 families. Moreover in 8 families ring-shaped sclerotizations are found in the ventral wall of the vagina. While these characters could help to resolve phylogenetic questions, such as the position of Cremifanniidae, Neminidae, and Acartophthalmidae, the occurrence of additional evaginations of the vagina does not seem informative above the family level.

These data are a valuable resource to other researchers, providing information about conditions within families as well as comparative information about outgroups.

01-097

MOLECULAR PHYLOGENETIC ANALYSIS OF DIPTERAN PHYLOGENY BASED ON 28S RIBOSOMAL DNA SEQUENCES

M. Friedrich, D. Tautz

Zoologisches Institut der Universität München, München, Germany

The long standing issue of Dipteran phylogeny has remained very controversial. More recently, the results of a cladistic analysis by Wood and Borkent (1989) primarily using larval character states suggested the polyphyly of two of the major subgroups, the Bibionomorpha sensu lato and the Tipulomorpha sensu lato, as they were proposed by Hennig (1981) mainly based on adult character states.

We have approached this problem by means of molecular phylogenetic analysis. We have sequenced DNA fragments encompassing the D1 and D7 region of the large ribosomal subunit RNA (28S rRNA) from a number of Dipteran species and representatives of closely related holometabolous insect orders. In the molecular phylogenetic reconstruction, monophyly is highly supported in the case of five major Dipteran subgroups, namely Brachycera, Tipulomorpha sensu stricto, Bibionomorpha sensu lato, Culicomorpha and Psychodomorpha. Accordingly, the controversial subgroup Bibionomorpha includes the families Sciaridae, Mycetophilidae, Cecidomyiidae, Scatopsidae and Anisopodidae as proposed by Hennig (1981), while the phylogenetic position of the Trichoceridae remains uncertain.

However, the phylogenetic relationships between these major subdivisions could not be robustly resolved with the present amount of sequence data. Still, morphological and additional molecular sequence data consistently support a sistergroup relationship between Bibionomorpha and Brachycera.

01-099

THE IMPORTANCE OF FOSSIL MATERIALS TO INVESTIGATIONS ON HIGHER-LEVEL PHYLOGENY OF THE DIPTERA

Wiesław Krzemiński

Institute of Systematics & Evolution of Animals, Pol. Acad. Sci., Kraków, Poland

The oldest fossil Diptera from Lower/Middle Triassic of France (Krzemiński et al. 1994), from Middle/Upper Triassic of Asia (Shcherbakov et al., 1995) and from Lower Jurassic of Germany (Ansorge, 1994) allow to verify some concepts concerning relations between large lineages of Diptera and to explain homology of some veins (especially of anal field) of Diptera and Mecoptera.

1. *Grauvogelia arzwilleriana* from France, the oldest fossil fly known, has venation showing a combination of characters observed in different dipteran groups and does not fit any previous groundplan of dipteran wing.

2. One specimen from Lower/Middle Triassic of France (in prep.), and Diptera from Triassic of Asia: *Gonomusca renyxa*, *Psychotipa predicta*, *P. depicta*, *Mabelysia charlesi* show gradual elongation of A2 in Polyneura.

3. Lower Jurassic species, *Nannotanyderus krzemiński* (Tanyderidae) and *Tanypteryx connexa* (Psychodidae) of venation close to tanyderid type (with d cell) prove that Psychodidae had branched off the Tanyderidae. Both families represent the most primitive dipteran lineage, the Diarchineura (Krzemiński, 1992).

01-100

THE WING ULTRASTRUCTURE OF BIBIONOMORPHA AND ITS EVOLUTIONARY SIGNIFICANCE

N.P. Krivosheina, A.I. Zaitzev

Institute of Ecology and Evolution RAS, Moscow, Russia

The comparative study of wing ultrastructure was fulfilled. The representatives of several, previously considered to be related, families of Bibionomorpha: Bibionidae, Pachyneuridae, Pleciidae, Cramptonomyiidae, Hesperinidae, Mycetobiidae, Canthyloscelidae and Axymyiidae were chosen for the investigation. The results demonstrated the next objectives: the structure and pattern of macro- and microtrichia of wing have certain significance for the specifying of relationships. Sharp difference between *Mycetobia-Hyperoscelis-Protaxomyia* group and the rest of bibionoid flies testify to more fractional division of Nematocera into infraorders.

01-102

ADULT CHARACTERS VERSUS LARVAL CHARACTERS IN PHYLOGENETIC STUDIES OF THE SCIOMYZOIDEA (CYCLORRHAPHA)

R. Meier

Department of Entomology; American Museum of Natural History, New York, U.S.A.

The Sciomyzoidea are a problematic higher taxon within the acalyptate flies for several reasons: (1) Its monophyly is not supported by convincing characters. (2) Its composition is controversial with only Griffiths including the Cremifanniidae and Megamerinidae. (3) The limits of the largest family, the Sciomyzidae, are uncertain. The Salticellinae and Sciomyzinae form an undisputed monophyletic core group (Sciomyzidae sensu strictu), but its relationships to the Huttoninac, Phaeomyiinae and Helosciomyzinae are unclear. (4) The relationships among the constituent families of the Sciomyzoidea are unresolved. Hennig only recognizes one monophyletic group (Ropalomeridae + Sepsidae). J. McAlpine argues for an additional one consisting of the Sciomyzidae sensu lato and the Dryomyzidae and a basal position of the Coelopidae. D. McAlpine argues for a sister-group relationship between the Coelopidae and Dryomyzidae.

Larval characters have been largely ignored although they proved useful for a discussion of the relationships within the Sciomyzidae s.l. (Knutson et al.) and Sepsidae. Based on the tubercles of the last segment, the Sciomyzoidea can be divided into two groups. Several pairs of tubercles are found in the Dryomyzidae, Sciomyzidae s.s., and Helosciomyzidae. Unknown from the closely related families in the Lauxanoidea, the tubercles are putatively homologous and consistent with J. McAlpine's monophyletic group consisting of the Dryomyzidae and Sciomyzidae s.l.. However, larval characters do not necessarily clarify the phylogenetic discussion. For example, several characters point towards a sister-group relationship between the Sepsidae and Coelopidae questioning the one longstanding monophyletic group within the Sciomyzoidea that is supported by adult characters.

Despite the confusion about the composition and relationships, the Sciomyzoidea, rich in unusual natural history, deserve more attention. Some larvae are predators or parasites of molluscs (Sciomyzidae s.s.), barnacles (*Oedoparena*, Dryomyzidae), millipeds (*Pelidnoptera*, Phaeomyiinae), and possibly ant larvae (Helosciomyzidae). But whether the parasitic or predatory modes of life evolved independently will remain unknown until the phylogenetic relationships have been reconstructed.

01-101

PHYLOGENETIC UTILITY OF NUCLEAR GENES IN THE STUDY OF NEMATOCERA RELATIONSHIPS

V. L. Kulasekera and R. DeSalle

Department of Entomology; American Museum of Natural History, New York, U.S.A.

The suborder Nematocera is an important group of flies within Diptera as most of the disease vectors such as mosquitoes, sand flies, biting midges and black flies are included within this group. Recent phylogenetic studies have generated opposing views regarding the relationships within Nematocera. The major points of discrepancy are: (1) Wood and Borkent placed Tipulidae as the sister group to rest of the Diptera and moved Trichoceridae to the Psychodomorpha clade. Oosterbroek and Courtney placed Tipulidae+Trichoceridae clade as the sister group to Anisopodidae+Brachycera while Ptychopteromorpha+Culicomorpha was placed as the sister group to all other Diptera. (2) Aximyidae was removed from the Bibionomorpha clade and placed in a separate clade by Wood and Borkent, whereas in the latter study Aximyidae was the basal taxon in the Bibionomorpha clade. Oosterbroek and Courtney attribute the difficulties in interpreting relationships within Nematocera to the vast diversity of morphological characters, discrepancy between adult and larval characters, homoplasy, and lack of understanding of all character systems. Therefore, in order to resolve the relationships within Nematocera it is essential to look for new character data sets such as molecular characters.

Since character consistency appears to be a major factor in resolving the phylogenetic relationships of this group, we have undertaken an analysis of the phylogenetic signal present in several nuclear gene systems for this taxonomic level, by using representatives of ten families of Diptera. These gene systems are phosphoenolpyruvate carboxykinase, wingless, enolase, dopa decarboxylase and 18S rRNA. We present two ways of assessing the utility of these gene systems. First, we will compare the degree of character consistency and retention in each data set, and the degree of sequence divergence in pairwise comparisons. Second, we will place the character information in a total evidence (simultaneous analysis) framework and examine these characters on the basis of character congruence. We will incorporate morphological data also into the total evidence framework, and test congruence of the various character sets with each other and the total evidence hypothesis using the Incongruence Length Difference of Farris and Mckevich (ILD). A consideration of a combination of the ILD studies, and the saturation and consistency studies will give a more complete picture of the utility of these character sets.

01-103

CRANEFLY PHYLOGENY: A CLADISTIC ASSESSMENT OF MORPHOLOGICAL CHARACTERS OF THE ADULT HEAD AND THORAX (DIPTERA: TIPULOIDEA)

V. Michelsen

Department of Entomology, Zoological Museum, University of Copenhagen, Denmark.

The relationships of the major tipuloid lineages are cladistically analyzed using the parsimony program NONA. More than seventy characters, all pertaining to the skeleton and musculature of the head and thorax of the adults, have been scored for 23 exemplar species of crane flies belonging to the traditional families Tipulidae s.s. (2), Cylandrotomidae (1) and Limoniidae (20). The analysis also includes species of Mecoptera and Diptera (Trichoceridae, Tanyderidae, Ptychopteridae, Tabanidae) as outgroup taxa.

The results of the analysis are presented and used to assess the monophyly and cladistic affinities of the Tipuloidea. Further, my results are compared with previous, manual attempts on revealing the phylogeny of crane flies, notably those of Stary (1992) who based his analysis on a small selection of adult characters, and Oosterbroek & Theowald (1991) who used a large number of larval and pupal characters.

Finally, the prospects of arriving at a satisfactory family-group classification of the crane flies are outlined.

01-104

PHYLOGENY AND GEOGRAPHICAL DISTRIBUTION OF *ACHALCUS* (DOLICHOPODIDAE, DIPTERA)

M. Pollet

Department of Entomology, Koninklijk Belgisch Instituut voor Natuurwetenschappen, Brussels, Belgium

The genus *Achalcus* Loew, 1857 has a peculiar geographical distribution which is restricted to the temperate climatic zones of the world. The Holarctic (2 species) and Palearctic Regions (5 sp.) are considered to be rather poor in species, whereas a considerably richer fauna occurs in the Neotropical (Southern Chile: 3 sp. + at least 7 undescribed sp.) and Australasian Regions (Australia: 20-25 undescribed sp., New Zealand: 8 sp.).

Most Palearctic species seem to prefer marshland habitats and reedmarshes (*Phragmites australis*) in particular, except for *A. melanotrichus*, which is entirely confined to tree rotholes in which its larvae seem to breed. My recent systematic revision of the Palearctic *Achalcus* fauna not only added 4 new species to science but also revealed a considerable morphological difference between the arboreal *A. melanotrichus* and its congeners. This study also demonstrated that *A. melanotrichus* showed the most primitive features. As southern Chilean species are known almost exclusively from *Notophagus* woodlands and most Australian species are considered to be arboreal too, the phylogenetic relationship between the Holarctic, Neotropic and Australasian species is investigated, with special emphasis on the phylogenetic position of *A. melanotrichus*.

Data on their phylogeny and ecology are analyzed in an attempt to explain their present disrupted geographical distribution by reconstruction of the dispersal routes of ancestral species.

01-106

PHYLOGENY AND EVOLUTION OF THE GENUS *RHAGOLETIS* (DIPTERA: TEPHRITIDAE)

J. J. Smith, G. L. Bush

Department of Zoology, Michigan State University, East Lansing, MI USA

The genus *Rhagoletis* (Diptera: Tephritidae) is composed of more than 60 described species distributed throughout Eurasia and the New World. Several *Rhagoletis* species are agricultural pests, infesting fruit of apple, cherry, blueberry, currants and walnuts. Because many *Rhagoletis* species are thought to have arisen in sympatry by shifting and subsequently adapting to new host plants, *Rhagoletis* is also a model system for studying modes and mechanisms of speciation. To study the evolution of host preference and establish the historical pattern of host shifts and speciation in *Rhagoletis*, we are using molecular and morphological characters to resolve phylogenetic relationships both within *Rhagoletis*, and between *Rhagoletis* and its Trypetine relatives. Interestingly, within two taxonomically-defined *Rhagoletis* species groups, morphological and molecular characters give conflicting phylogenies. *R. pomonella* and *R. cornivora*, and *R. cerasi* and *R. berberides*, represent two pairs of sibling species that are essentially indistinguishable using morphological characters. However, genetic distances based on both allozyme and mitochondrial DNA data suggest deep genetic divergence within each species pair. Possible explanations for this difference in morphological and genetic divergence (lineage sorting, selection, etc.) will be examined. Analyses of morphology, allozymes and mitochondrial DNA support the idea that *Rhagoletis* species in North American species groups form a monophyletic group. However, *Rhagoletis* monophyly breaks down when species in North American, Palearctic and Neotropical species groups are considered together. Previous ideas on the evolutionary origins of the North American *Rhagoletis* will be examined in the context of our current data, as will the apparently complex relationships between organisms currently classified as *Rhagoletis* and flies in other Trypetine genera (e.g. *Zonosemata*, *Oedicarena*, *Rhagoletotrypeta* and *Carpomya*).

01-105

THE PHYLOGENETIC RELATIONSHIPS OF THE CALLIPHORIDAE AND MYSTACINOBIIDAE (DIPTERA, OESTROIDEA)

K. Rognes

Stavanger College, School of Teachers' Education, Stavanger, Norway

23 monophyletic taxa within the Oestroidea and two outgroup taxa (Muscidae and Anthomyiidae) were scored for 45 adult and larval characters and subjected to phylogenetic analyses searching for trees of maximum total fit (using Pee-Wee) or minimum length (using NONA and PAUP). The former gave 9 different trees for possible values of the concavity constant, all differing from the two minimal length trees. The trees obtained from maximum-fit searches are preferred since derived from a method that lowers the weight of characters showing within-terminal as well as within-tree homoplasy. The family "Calliphoridae" in various commonly used senses (excluding Oestridae s.lat.; including the Rhiniinae; excluding or including the Rhinophoridae; excluding or including *Mystacinobia*) does not appear to be monophyletic, though it does in trees having a much lower total fit, and in a very small fraction of the numerous trees 5 or 9 steps longer than the minimum-length trees. The assemblage (Rhiniinae + Toxotarsinae + Chrysomyinae) should likewise be rejected. A clade (Ameniini + *Euphumosia* + Phumosiinae + Mesembrinellinae + Parameniini + *Catapicephala*) is possibly Gondwanian. A clade (Toxotarsinae + Chrysomyinae + Calliphorinae + Luciliinae + Melanomyiinae) contains all the sarcosaprophagous "blowflies". The clades (Auchmeromyiinae + Bengaliinae) and (Chrysomyinae + Toxotarsinae) are the best supported groups. The group (Tachinidae + Sarcophagidae) is possibly the monophyletic sister-group of the Rhiniinae. *Mystacinobia* emerges from the analyses as the sister-group of all other Oestroidea and the Axiniidae as the sister-group of all the non-mystacinobiine oestroids. Although *Mystacinobia* is a guano-feeder in all stages, the biology of the other basal oestroid taxa indicates that reproductive association with small, living or dead, invertebrates is a primitive oestroid pattern.

01-107

PROPOSALS FOR THE PHYLOGENETIC CLASSIFICATION OF THE EMPIDOIDEA, OR ORTHOGENYA (DIPTERA, EREMO-NEURA)

H. Ulrich

Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn, Germany

This is a discussion of how the current and partly conflicting hypotheses about the phylogeny of the Empidoidea and Eremoneura are to be translated into a consistent phylogenetic classification. The Empidoidea, including the Atelestidae or not, are likely to be a monophylum and the sister group of the Cyclorhapha. On the other hand, there is little doubt that the traditional concept of Empididae is paraphyletic. It is obligatory to subdivide the Empidoidea into monophyletic groups, the categorical ranks of which should be chosen consistently with those to be accepted within the Cyclorhapha. The same rank should be given to respective sister groups and to taxa of approximately equal geological age. In consequence, the number of families will have to be drastically reduced within the Cyclorhapha, whereas it may have to be increased in the Empidoidea. Thus, some or all of the conventional subfamilies in the Empididae and Hybotidae sensu Chvála 1983 may deserve the rank of families.

01-108

PHYLOGENY OF THE LOWER BRACHYCERA (DIPTERA):
MORPHOLOGICAL AND MOLECULAR EVIDENCEB. M. Wiegmann, D. Yeates¹, S.C. Tsaur²

Department of Entomology, North Carolina State University, Raleigh, NC, USA; - 1 Department of Entomology, University of Queensland, Brisbane, Qld. 4072, Australia; - 2 Department of Ecology and Evolution, University of Chicago, Chicago, Illinois, USA.

Phylogenetic relationships among the earliest lineages of the Brachycera have been difficult to resolve based on morphological features alone. Particularly contentious are relationships among the major subgroups of the superfamilies Stratiomyoidea, Empidoidea and Asiloidea. For example, at least six alternative hypotheses have been raised for relationships among families of the Asiloidea. Here we review and reexamine evidence on the higher-level phylogeny of the 'orthorrhaphous' Brachycera. Nucleotide sequence data may shed new light on relationships of the basal Brachycera. We have sequenced large portions of three genes, phosphoenolpyruvate carboxykinase (PEPCK), 18S ribosomal RNA, and 28S ribosomal RNA for taxa spanning the diversity of non-cyclorrhaphous Brachycera. In combined and separate phylogenetic analyses of morphological and molecular data we examine the strength of support for competing hypotheses of relationship for lower brachyceran lineages. Emphasis is placed on the position of the Bombyliidae, monophyly and relationships of the Asiloidea, and the position of several critical taxa including *Heterotropus*, *Hilarimorpha*, and Pantophthalmidae.

01-110

DIVERSITY OF ANTENNAL SENSORIA IN THE BASAL
CLADES OF THE THYSANOPTERA

R. Marullo

Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy

The possible origin of the diverse sensoria on antennal segments III-IV in the two families Merothripidae and Aeolothripidae (Thysanoptera, Insecta) is examined. An hypothesis of polarity of relationships between 18 genera - relating to both number and shape of the antennal sensoria - is provided.

01-109

THE IMPACT OF FOUNDING NUMBER AND
KLEPTOPARASITISM ON THE SEX RATIO OF A EUSOCIAL AND
A NON-EUSOCIAL GALL-FORMING AUSTRALIAN THRIPS SP.
(THYSANOPTERA: PHLAEOTHIRIPIDAE) ON *ACACIA*
*CAMBAGEI*B.D. Kranz, M.P. Schwarz¹, B.J. Crespi², L.A. Mound³

¹School of Biological Sciences, Flinders University of South Australia, Australia

²Dept of Biological Sciences, Simon Fraser University, Burnaby, Canada

³CSIRO Division of Entomology, Canberra, Australia

The thrips *Kladothrips ellobus* and *K. hamiltoni* form galls on *Acacia cambagei* in the Lake Eyre basin of Australia. *K. ellobus* forms disc-like galls of about 1.5cm in diameter. Single generations of thrips are reared in these galls and mortality, due to invasion by the kleptoparasitic thrips, *Koptothrips xenus*, is high. *K. hamiltoni* forms tubular galls of about 3cm in length, where at least two generations of thrips are reared. The first generation comprises females and males which are micropterous, have enlarged fore-femurs and reduced antennae, and who act as soldiers in defence of the gall occupants. This species is threatened by invasion of *Koptothrips flavicornis* and an undescribed species of *Koptothrips*. Galls of *K. ellobus* and *K. hamiltoni* are founded by either a single female or a male and a female. The variation in sex ratios of eggs, nymphs and adults of these gall-formers, following both gall-induction and invasion, are quantified. Reasons for these variations, and differences between species, are discussed in the context of queen-worker conflict and defence strategies.

01-111

MISLEADING METHODOLOGIES IN THRIPS TAXONOMY:
HOSTS, HABITATS, HYPOTHESES AND MENSURATION

Laurence A. Mound

Division of Entomology, CSIRO, Canberra, Australia

Thrips host and habitat records that are based on single individuals may indicate little more than that thrips are highly vagile. To be useful to other biologists interested in host-plant and habitat ranges, both for economic and academic purposes, such records need to be based on the presence of larvae; that is, on those plants without which a thrips population cannot regenerate. Similarly, in descriptive taxonomy, data accumulation with little consideration of thrips as three-dimensional objects varying in time and space can produce misleading results. For example, head or setal lengths to 1% precision, with means to 0.05% precision, ignore the fact that specimen orientation on a microslide precludes such accuracy. Such data, accumulated without the conscious objective of facilitating comparisons, is part of the traditional approach to descriptive taxonomy that needs reconsideration. As in any other branch of science, taxonomy should involve the creation and testing of hypotheses, but to do this methodologies must be purposeful and standardised. The failure of so many taxonomic hypotheses concerning thrips, with more than 20% of species now being placed into synonymy, results from inadequate comparative methodology. The objective of this talk is to provoke a discussion of how thrips taxonomy might become more purposeful.

01-112

GENETIC VARIATION OF *THRIPS NIGROPILOSUS* WITH A DISCUSSION OF ITS TAXONOMIC TREATMENT (THYSANOPTERA: THIRIPIDAE)

S. Nakao, M. Muraji¹

Laboratory of Entomology, Faculty of Agriculture, Kyoto Prefectural University, Kyoto, Japan - ¹ Department of Insect Genetics and Breeding, National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan

Thrips nigropilosus is widespread in the Northern Hemisphere, and females of this thrips exhibit a wing polymorphism. Recently, it was revealed that arrhenotokous and permanently thelytokous populations occur in Japanese *T. nigropilosus*, and that the former is divided into 3 groups with different genetic components of brachyptery. No genetic variability has been detected within the thelytokous thrips. Thus *T. nigropilosus* consists of 4 groups in Japan.

In this article, morphological characters, esterase zymograms, and partial nucleotide sequences of CO I and 16S rRNA genes of mitochondrial DNA were analyzed in adult females of the 4 groups, to clarify phylogenetic relationships among them and their taxonomic status. The arrhenotokous females were different from the thelytokous ones on development of sculpture on the ninth abdominal tergite and esterase zymograms, whereas the arrhenotokous females of the different groups could not be discriminated from each other by these characters. Sequence differences among the 4 groups were 0–3.6% in the CO I gene and 0–1.3% in the 16S rRNA gene. Molecular phylogenetic trees of the CO I nucleotide sequences revealed that females from the 4 groups are divided into 2 major clusters: arrhenotokous and thelytokous populations. These results suggested that the arrhenotokous populations with different genetic components of brachyptery are classified as a monophyletic group, and that the arrhenotokous populations and the thelytokous one should be recognized as separate species.

01-114

THE COMPLEX OF PHILIPPINE *Gynaikothrips* SPECIES

C. P. Reyes

Research Division, YLFI-Emilio Aguinaldo College Ermita, Manila, Philippines

Gynaikothrips are medium-sized to large thrips distributed mainly in the Orient with a few species known from the new world. There are six known species of *Gynaikothrips* in the Philippines: *Gynaikothrips uzeli* Zimmermann, *Gynaikothrips luzonensis* Priesner, *Gynaikothrips capitulatus* Reyes, *Gynaikothrips pedanus* Reyes, *Gynaikothrips pontis* Reyes and *Gynaikothrips xynos* Reyes.

The species of *Gynaikothrips* in the Philippines can be grouped into four: 1) *uzeli* group: *G. uzeli* 2) *luzonensis* group: *G. luzonensis* 3) *pedanus* group: *G. capitulatus* and *G. pedanus* 4) *pontis* group: *G. xynos* and *G. pontis*. The first three groups possess adult characters which definitely placed them under *Gynaikothrips* while the *pontis* group possesses characters that grade from those of adult *Gynaikothrips* and *Gigantothrips*.

Genera *Gynaikothrips* and *Gigantothrips* were described by Zimmermann in 1900. Members of these two genera are indistinguishable except for the longer intermediate antennal segments and body, additional pairs of wing retaining and accessory setae, and presence of foretarsal tooth in *Gigantothrips* species.

01-113

RELATIONSHIPS BETWEEN THYSANOPTERA AND THE REPRODUCTIVE AND VEGETATIVE PARTS OF *PROTEA* SPECIES (PROTEACEAE) FROM THE DRakensBERG MOUNTAINS OF SOUTH AFRICA

L.T.P. Pajor¹, R. zur Strassen², M.J. Samways¹

¹ Invertebrate Conservation Research Centre, Department of Zoology & Entomology, University of Natal, Pietermaritzburg, South Africa

² Forschungsinstitut und Naturmuseum Senckenberg, Frankfurt am Main, Germany

On five species of *Protea* L. in the summer rainfall region in the south east of Africa, were recorded 37 species of Thysanoptera. The Terebrantia with 23 species in 16 genera were almost twice as abundant as the Tubulifera (8 genera, 14 species). Similarly, of the total of fifteen species in the inflorescence, only 3 belonged to the Tubulifera. The most abundant species on the leaves of these proteas was an unidentified *Scirtothrips* species, together with far less numerous members of another 3 species of Thripidae and one Phlaeothripidae. The *Scirtothrips* sp. fed regularly on the young leaves of *Protea caffra*. Only *Megalurothrips sjostedti* (Thripidae) could be found on both foliar and reproductive parts of these plants.

While species of Thripidae are quite likely to be involved in pollination by entering the florets already in the bud stage, members of the Tubulifera appear only much later and probably have no role in the pollination process. Thrips, together with other small florivore insects, can achieve high pollination rates of over 50%. However, the germination ability of these seeds in *P. caffra* is strongly reduced when compared with seeds from out-crossed pollination. Our results, compared with those from the Cape Floristic Region, reveal a very different thrips assemblage, with Tubulifera being dominant in the Cape but not in the Drakensberg mountains.

01-115

HOW TO CLASSIFY THE SPECIES OF THE GENUS *THRIPS* LINNAEUS (INSECTA: THYSANOPTERA).

R. zur Strassen

Research Institute Senckenberg, Frankfurt am Main, Germany

The genus *Thrips* Linnaeus 1758 is one of the largest genera in the order Thysanoptera comprising about 220 species world-wide. It is difficult to prepare for this genus a useful key to species based on easily recognizable features. It is much more difficult to work out a key to species based on characters which will allow phylogenetic groupings of the species.

Reduction of certain features or morphological dispositions are regarded as apomorphic. In any group of species such reductions occur in different combinations of characters. On the other side, the same species exhibit ancestral features also in different combinations.

In order to get an approximate phylogenetic line of the species of each group, the question has to be discussed which of the ancestral (plesiomorphic) characters are „older“ than other ones, and in contrast, which of the apomorphic characters are „younger“ than others. For an example, the hairy *Thrips minutissimus* Linnaeus 1758, a common European inhabitant of deciduous trees, shows plesiomorphic as well as apomorphic features. Does the species belong in its group to the ancestral representatives or to the advanced ones? Further details will be discussed.

01-116

CLASSIFICATION AND PHYLOGENY OF THE NEUROPTEROIDEA: AN INTRODUCTION

Ulrike Aspöck

Naturhistorisches Museum Wien, Vienna, Austria

Presently three orders are integrated within Neuropteroidea (= Neuropterida): Megaloptera, Raphidioptera, and Neuroptera s. str. The hypothesis of a sistergroup relationship (M+R)+N has been the predominantly accepted one. Arguments for an alternative hypothesis: (M+N)+R are presented. The new approach is mainly basing upon the larvae.

Aquatic larvae of the Megaloptera have so far been interpreted as an autapomorphy of this order, and aquatic larvae of the neuropteran Nevrothidae and Sisyridae as apomorphy of each family respectively. The new hypothesis interprets aquatic larvae of both orders as a plesiomorphic state, deriving, however, from a common ancestor, thus being a synapomorphy of M+N. Terrestrial, cryptonephric larvae within Neuroptera s. str. consequently are secondary.

In addition: Due to the morphology of larval mouthparts in Megaloptera evolving of neuropteran sucking tubes seems to be more parsimonious from a common ancestor of M+N than from a common stem species of the N+R.

As a consequence of the turned character polarity of aquatic/terrestrial larvae changed sistergroup relationships within Neuroptera s. str. result: (Nevrothiformia + Myrmeleontiformia) + Hemerobiiformia - within the Hemerobiiformia the Sisyridae being the adelphotaxon of all the other families.

01-118

THE METATHORACIC GLAND SYSTEM IN THE EVOLUTION OF THE FAMILY MYRMELEONTIDAE (NEUROPTERA)

R. Güsten

Institut für Zoologie, Technische Hochschule, Darmstadt, Germany

The Metathoracic Gland System of antlions consists of at least one pair of glandular reservoirs opening between the metathorax and the 1st abdominal segment, and in some cases a functional unit for secretion distribution. The latter is comprised of the pilula axillaris on the hindwing together with a pouch-like structure on the 1st abdominal segment. The secretion of the metathoracic gland purportedly acts as a male sexual pheromone. Interestingly, the gland system occurs in females as well, albeit in a reduced state.

For several species of Myrmeleontidae from different tribes, data are presented on the structure of the Metathoracic Gland System. It is argued that this set of organs forms part of the family's ground plan. Morphological peculiarities of its components may provide phylogenetically useful information to elucidate the still poorly resolved myrmeleontid phylogeny. Other exocrine gland systems confined to males are known in antlions, but in many taxa, only one source for pheromones appears functional. In some groups, however, males possess more than one type of well developed glandular organs, suggesting highly elaborated mating systems. Furthermore, secretions from reduced metathoracic glands of females might play an additional role in courtship. Glandular condition in females may nevertheless be interpreted as rudimentary, originating from a situation of equally developed Metathoracic Gland Systems in both sexes serving another function, such as defence.

Methods relevant for the investigation of exocrine glandular structures as presented here include scanning and transmission electron microscopy, and analytical techniques for the study of secretion chemistry. Preservation methods for material used in the investigation of different traits of the Metathoracic Gland System and of exocrine glands in Neuroptera in general are outlined.

01-117

THE CLASSIFICATION OF THE MYRMELEONTIDAE: CURRENT PROBLEMS AND ATTEMPTS TOWARDS A SOLUTION

H. Hölzel

Brückl, Austria

The current classification of the Myrmeleontidae recognizes three subfamilies: Palparinae, Stilbopertyginae (two Australian genera with nine spec.) seem to be beyond dispute at present, the arrangement of the other two subfamilies is controversial. The Palparinae include with certainty only the tribe Palparini, whereas the position of the Palparidiini seems to be questionable. Indisputable tribes belonging to the Myrmeleontinae are the Myrmeleontini, Acanthaclisini, Dendroleontini (all worldwide) and the Brachynemurini, Lemolemini and Gnopholeontini in the New World. The current construction of the Myrmecaelurini, Nesoleontini, and Nemoleontini is controversial and characters to delimit the Glenurini from the Nemoleontini and Gepini from the Myrmecaelurini are discussed. The reinstatement of Glenurini and Gepini is proposed.

01-119

AN OVERVIEW OF THE CURRENT STATUS OF CHRYSOPIDAE (NEUROPTERA) SYSTEMATICS

Stephen J. Brooks

Department of Entomology, Natural History Museum, Cromwell Road, London, UK

Despite considerable progress in chrysopid systematics in recent years there are still many problems to be resolved. The relationships between the tribes and subfamilies of Chrysopidae are largely undetermined at present and monophyly of some, such as the Nothochrysinæ, have not been demonstrated. These problems are examined and a phylogeny for the chrysopid tribes and subfamilies is proposed. The relationships between the genera within the tribes and subfamilies are still unclear in many cases. This is particularly problematic in the Chrysopini, which includes nearly half the chrysopid genera. The systematics of the Nothochrysinæ and Chrysopini is reappraised and the value of certain morphological characters in resolving these problems are discussed. New work on courtship songs has revealed the presence of morphologically indistinguishable "song-species" in *Chrysoperla*, and the limitations of reliance solely on morphological characters to distinguish species. The implications of this in traditional taxonomic studies of Chrysopidae are briefly discussed.

01-120

THE *CHRYSOPERLA CARNEA* COMPLEX

P. Duelli, C.S. Henry¹, S.J. Brooks², J.B. Johnson³

Swiss Federal Institute for Forest, Snow and Landscape Research, CH-8903 Birmensdorf, Switzerland - 1 Biological Sciences Group, Univ. of Connecticut, Storrs, CT 06268, USA - 2 The Natural History Museum, Cromwell Road, GB London SW7 5BD, UK - 3 Dept. of Plant, Soil and Entomol. Sciences, Univ. of Idaho, Moscow, Idaho, 83843-4196, USA

There is growing evidence that the holarctic common green lacewing, "*Chrysoperla carnea* Stephens", in fact consists of a number of valid sibling species and "song taxa". One of the best tools to separate and identify biological species in the genus *Chrysoperla* Steinmann is the analysis of the species specific vibrational courtship signals, which are performed by males and females in a duet as a precursor to copulation. At least ten more or less cryptic "song taxa" of the *carnea*-complex have been analyzed in the USA (3 spp.), in Europe (4 spp.) and Asia (5 spp.), and the number is growing yearly.

The splitting of a widespread species of such ecological and economic importance raises problems for science (how to interpret previous research findings?), biological control (mass rearing and release: the right species?), as well as conservation and law (shipping and introducing foreign species). An international "Working Group *carnea* complex" (WGcc) was established to investigate the taxonomy, systematics, biology and ecology of the various sibling species. A summary of present knowledge is given in the talk.

01-122

NEUROPTERA OF AUSTRALIA: ORIGINS, DIVERSITY AND RELATIONSHIPS

T.R. New

School of Zoology, La Trobe University, Bundoora, Victoria, Australia.

The Australian Neuroptera fauna is large (>600 species) and diverse (14 families), with many archaic lineages and high levels of endemism. Recent comparative studies on the Neuroptera of Papua New Guinea, Indonesia and Malaysia have helped to clarify the peculiarities of the Australian fauna. Ancient Gondwana elements can be defined clearly, and the groups originating from the Indo-Malayan region are also largely definable. Biogeographical relationships of Australian Neuroptera are categorised and discussed in the perspective of current distribution patterns and centres of diversity.

01-121

SPECIES COMPLEXES AND SIBLING SPECIES IN CHRYSOPID LACEWINGS (NEUROPTERA, CHRYSOPIDAE)

R. Cianchi and L. Bullini

Dipartimento di Genetica e Biologia Molecolare, Università di Roma "La Sapienza", via Lancisi 29, I-00161 Roma, Italy

A number of sibling species has been discovered in recent years in chrysopid lacewings, mainly using three distinct approaches: 1) genetic structure by isozyme markers (Bullini & Cianchi, 1984; Cianchi & Bullini, 1992); 2) courtship call patterns (Henry, 1983, 1985); 3) microhabitat and phenology (Thierry *et al.*, 1992, 1995).

In the present note, the *Chrysoperla carnea* and *Mallada prasinus* complexes are reviewed. Genetic differentiation and allopatric versus sympatric modes of speciation in the two species complexes are discussed.

01-123

THE EXTANT DISTRIBUTION OF THE ORDER RAPHIIDOPTERA: A BIOGEOGRAPHICAL AND PHYLOGENETIC PERSPECTIVE

H. Aspöck

Abteilung Medizinische Parasitologie, Hygiene-Institut der Universität Wien, Austria

The extant distribution of the Neuropteroid order Raphidioptera is restricted to certain arboreal parts of the Holarctic. It covers probably all arboreal regions of the Palearctic, in the Nearctic, however, it is confined to the south and southwest of North America, although northern and eastern parts of the continent would offer ecologically perfect conditions. The southern hemisphere presently lacks Raphidioptera totally.

There have been numerous efforts to explain this peculiar distribution pattern, but only recent results coming from various disciplines and from a reconsideration of relationships within the two families of the order (particularly Raphidiidae) have yielded sufficient arguments for the following assumptions: (1) The distribution of Raphidioptera during the Mesozoic must have been much wider and has included tropical and subtropical parts of the southern hemisphere, (2) the extant snake-flies of America are the remnants of ancestors having reached (South) America before the separation of South America from Africa and (3) by far most of all Raphidioptera have died out at the end of the Cretaceous except those which already had adapted to a temperate or a cold climate.

01-124

PHYLOGENY OF THE MOST PRIMITIVE LEPIDOPTERA:
THE STATE OF THE ART

N.P. Kristensen

Zoological Museum, University of Copenhagen, Denmark

Relationships between the four basal clades within the Lepidoptera are arguably still best represented as Micropterigidae + (Agathiphagidae + (Heterobathmiidae + Glossata)), though both the Agathiphagidae and the Heterobathmiidae are known to possess apparently plesiomorphic traits unknown elsewhere in the 'order'.

The basal clades within the Glossata have now been found to constitute a highly resolved 'Hennigian comb':

Eriocraniidae + (Acanthopteroctetidae + (Lophocoronidae + (Neopseustidae + (Exoporia + Heteroneura)))). This phylogeny necessitates that reduction of the adult moth's mandibular musculature (and hence development of an adectic pupa) has occurred twice independently: in Lophocoronidae and in Neolepidoptera (= Exoporia + Heteroneura). On the other hand it permits us to continue to consider the development of an intrinsic proboscis musculature to be a unique event in lepidopteran evolution, hence a groundplan autapomorphy of the Myoglossata as first defined (= Neopseustidae + Neolepidoptera).

While the monophyly of the Heteroneura now appears reasonably well supported, the basal splitting events within the clade remain debatable. The arrangement Nepticuloidea + (Incurvarioidea + (Palaephatoidea + Tischerioidea + Ditrysia)) may tentatively be suggested on the basis of pheromone chemistry/female calling behaviour and eggshell ultrastructure.

As presently understood the basal lepidopteran cladogram indicates that the 'soil-animal' lifestyle of exoporian larvae is secondary. It cannot without ad hoc hypotheses be reconciled with the interpretation of an Upper Jurassic moth as belonging to the Glossata.

01-126

ADVANCES IN THE PHYLOGENETIC STUDY OF THE
ZYGAENOIDEAH. Geertsema, C.M. Naumann¹, G.M. Tarmann², M.E. Epstein³,
S.E. Miller⁴, A. Zilli⁵

Department of Entomology and Nematology, University of Stellenbosch, Stellenbosch, South Africa-¹ Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, D-53113 Bonn, Germany-² Tiroler Landesmuseum Ferdinandeum, Naturkundliche Sammlungen, Feldstr. 11a, A-6020 Innsbruck, Austria-³ Department of Entomology, Stop 105, Smithsonian Institution, NMNH, Washington, D.C. 20560, USA-⁴ Department of Entomology, Bishop Museum, Honolulu, Hawaii-⁵ Museo Civico Zoologia, Viale del Giardino Zoologico 20, I-00197 Rome, Italy

Nine families, Zygaenidae, Limacodidae, Megalopygidae, Somabrachyidae, Dalceridae, Chrysopolomidae, Epipyropidae, Heterogynidae and Cyclotornidae are usually included in the Zygaenoidea. The higher classification of the Zygaenoidea presently is unsatisfactory due to the lack of characterisation(s) by clearly defined automorphies of the constituent taxa. Some families are well defined by one or several automorphies but also share a great number of plesiomorphic characters and their relationship(s), inter as well as in some cases intra, remains problematic. More recently, some revisionary studies, and which are reported here, have resulted in a better understanding of the constituent taxa, establishing an improved basis for a possible phylogenetic classification of the Zygaenoidea.

01-125

PHYLOGENY AND BIOLOGY OF THE LOWER
DITRYSIA (TINEOIDEA, GRACILLARIOIDEA
AND YPONOMEUTOIDEA)

D. R. Davis

Department of Entomology, Smithsonian
Institution, Washington, D.C. USA

Although the three superfamilies discussed do not form a monophyletic group, they are customarily positioned together on the basis of several plesiomorphies at the base of the ditryisian Lepidoptera. Over the past decade investigations by several researchers have helped to clarify many relationships within each superfamily. Results of these studies are reviewed together with the biology and phylogeny of the currently recognized families. These include: (Tineoidea) Tineidae, Eriocottidae, Acrolophidae, Arrhenophanidae, Psychidae; (Gracillarioidea) Roeslerstammiidae, Douglassiidae, Gracillariidae; and (Yponomeutoidea) Yponomeutidae, Ypsolophidae, Plutellidae, Glyphipterigidae, Heliodinidae, Bedelliidae, Lyonetiidae. Also discussed are several problematic taxa for which family relationships still remain uncertain.

01-127

PHYLOGENY OF DITRYSIA

Joël Minet

Laboratoire d'Entomologie, 45 rue de Buffon,
F-75005 Paris, France

The phylogenetic schemes previously proposed by the author (from 1988 to 1994) are reassessed and compared with a few other recent assumptions, which were based on either morphological or molecular data. While the latter tend to support the author's views, certain morphologically based works lead to fairly different proposals, such as a polyphyletic nature of the Obtectomera, a diphyletic nature of the Macrolepidoptera or a sister group relationship between the Gelechioidea and Apoditrysia. However most of these innovations prove quite unacceptable since they are based on inaccurate evidence. The morphology of the imaginal labial palps apparently supports the Yponomeutoidea/Gelechioidea sister group relationship, which had already been suggested from studies of the pupae. A number of new clades are tentatively proposed within the non-macrolepidopteran Ditrysia after examination/re-examination of several insufficiently known characters (related to - e.g. - larval morphology, imaginal internal anatomy and wing base region). The morpho-anatomy of several moths representing "relict taxa" is shown to be of fundamental importance, and the necessity of weighting characters is advocated to obtain reliable phylogenetic reconstructions.

01-128

DEFINITION AND RELATIONSHIP: KEY WORDS FOR STUDIES IN THE PYRALOIDEA (LEPIDOPTERA) DURING THE LATE 20TH CENTURY

M. A. Solis

Systematic Entomology Laboratory, USDA, c/o National Museum of Natural History, Washington, DC

The Pyraloidea are one of the larger superfamilies of the Lepidoptera and many are pests to a wide array of crops and stored products. The two families, Pyralidae and Crambidae, comprise about 16,000 species worldwide. The delineation and relationships of higher-level taxa within the Pyraloidea have progressed rapidly during the latter part of this century, although activity at the species level has also exploded with the publication of major species lists from the Western Hemisphere and Australia.

The concept of the Pyraloidea has been refined tremendously during this century, although its sister-group relationship to other superfamilies remains unsolved. The definition and sister-group relationship of the Pyralidae and Crambidae based on adult and immature characters are reviewed. Studies on the subfamily relationships within each family are briefly reviewed. Recently, the use of characters associated with the tympanal organs on the first abdominal segment have been found to be useful in the delineation of taxa at various taxonomic levels in the Crambinae and Pyraustinae.

01-130

FOSSIL BUTTERFLIES IN PHYLOGENETIC PERSPECTIVE

R. de Jong

Department of Entomology, National Museum of Natural History, Leiden, The Netherlands

Fossilized butterfly remains are exceptionally rare. To date, 38 nominal species have been distinguished. The oldest known butterfly fossil is about 55 My old. In the lower Oligocene (about 35 Mya) all extant families are present. The known fossils stem from 11 sites in Europe, two in the U.S.A., one in Japan and one in Africa. The latter two sites are of Pleistocene age, the other sites range from Pliocene to lower Eocene. All body parts may be preserved, but the wings (with their venation) are predominant. The supposed taxonomic position is usually based on a comparison with an extant, modern species and conclusions are drawn without regard to the plesiomorphous or apomorphous nature of the similarity. Based on a critical evaluation the following number of fossil species can be assigned to family: Hesperidae - 1, Papilionidae - 5, Pieridae - 5, Lycaenidae - 2, Nymphalidae - 17, while the position of eight species remains uncertain. These numbers do not mirror the differences in species diversity among the modern butterfly families. The fossils are not helpful in solving problems with the higher classification of the extant butterflies. They do not contribute to the question of the origin of the butterflies either, except for the observation that the origin must have been before the Eocene.

01-129

PHYLOGENETIC PROBLEMS AND PROSPECTS IN THE MACROLEPIDOPTERA

I.J. Kitching

Biogeography & Conservation Laboratory, Department of Entomology, The Natural History Museum, London, Great Britain

Results of recent phylogenetic studies of family interrelationships within the four large superfamilies of Macrolepidoptera are reviewed. The position of Pieridae within Papilionoidea, as sister-group of either Papilionidae or Nymphalidae + Lycaenidae, remains contentious. Geometroidea is expanded to include Sematuridae and Uraniidae. Within Noctuoidea, the monophyly of Noctuidae is questioned; the catocaline group of subfamilies may be more closely related to Arctiidae + Lymantriidae than to the noctuine subfamily cluster. Within a restricted concept of Bombycoidea, two clades are recognized, centred on Saturniidae and Sphingidae.

Future analyses need to be more objective and integrate data from immature stages and DNA/RNA with that from adult morphology if they are to further resolve and clarify macrolepidoptera family and superfamily relationships.

01-131

NUCLEAR GENES FOR LEPIDOPTERAN SYSTEMATICS

J.C. Regier¹, C. Mitter², T.P. Friedlander², Q. Fang^{1,2}, B.M. Wiegmann³, S. Cho², A. Mitchell², R.W. Poole⁴, R.S. Peigler⁵, and E.S. Nielsen⁶

1 Center for Agricultural Biotechnology, University of Maryland, College Park, MD USA - 2 Department of Entomology, University of Maryland, College Park, MD USA - 3 Department of Entomology, North Carolina State University, Raleigh, NC USA - 4 Systematic Entomology Laboratory, USDA-ARS, Beltsville, MD USA - 5 Department of Zoology, Denver Museum of Natural History, Denver, CO USA - 6 Section of Taxonomy and General Biology, CSIRO Division of Entomology, Canberra, Australia

DNA sequences from five nuclear genes have been tested for their ability to resolve relationships among lepidopteran clades. These sequences encode dopa decarboxylase, elongation factor-1 α , *Per* locus, phosphoenolpyruvate carboxykinase and 18S ribosomal DNA. To date, phylogenetic analysis has focused on sub- and infra-ordinal relationships within non-ditrysian Lepidoptera, and on relationships within Noctuoidea (particularly Heliothinae) and Bombycoidea (particularly Saturniidae: Attacini and Sphingidae). Identifying an assortment of nuclear genes whose evolutionary rates differ should prove useful for resolving numerous relationships within the Lepidoptera, and beyond.

01-132

PHYLOGENETIC RELATIONSHIPS IN *YPONOMEUTA* (LEPIDOPTERA, YPONOMEUTIDAE) AND THE EVOLUTION OF INSECT-PLANT ASSOCIATIONS

Steph B.J. Menken & Nick Lieshout

Institute for Systematics and Population Biology, University of Amsterdam, the Netherlands

Progress in phylogenetic methodology and molecular biology, allowing for the reconstruction of phylogenetic relationships from molecular data, has facilitated the growing recognition of the significance of a historical perspective in ecology. The evolution of present day insect-host plant associations can be best understood by establishing phylogenetic relationships (from molecular, allozyme or morphological data sets) among extant species and subsequently mapping their host plants onto the insect cladogram.

Several provisional phylogenies of a variable number of *Yponomeuta* species are available, based on frequency data at some 50 allozyme and general protein loci and on DNA sequences of nuclear and mitochondrial genes.

Celastraceae (species of the genus *Euonymus* in particular) served as host plants of the common ancestor of *Yponomeuta* and still serve as host plants for the majority of *Yponomeuta* species. In the evolutionary past at least once a shift has been made to the taxonomically and phytochemically unrelated Rosaceae and further onwards to Salicaceae; another shift occurred to Crassulaceae. *Yponomeuta* is not an exception to the rule that in phytophages sequential evolution, i.e. the shift of insect herbivores onto pre-existing plant species, is more common than coevolution.

The genus seems to be committed to extreme specialization per se rather than to a particular group of plants: whatever shift they have made they remain monophagous; the oligophagous *Y. padellus* is the only exception. Specialists may be committed to remain so, not because of any selective advantage, but simply because they have little or no evolutionary opportunity to reverse the process due to constraints on the evolution of the insects' nervous system or physiology (e.g. to detoxify secondary plant compounds). Current phylogenetic evidence, however, indicates that there is no intrinsic direction to the evolution of specialization.

01-134

THE GENUS *CHIRODICA* GERMAR: A MEDLEY OF LEAF BEETLES (COLEOPTERA, CHRYSOMELIDAE)

M. Biondi

Dipartimento di Scienze Ambientali, Università di L'Aquila, Coppito (AQ), Italy

The flea beetle genus *Chirodica* was established by Germar in 1834 for the species *chalconera* from South Africa (Cape Province). Afterwards, other 8 species by three different authors were attributed to this genus: Baly (1876: *elongata*, *fulva*, *fulvipes*, *wollastoni*), Jacoby (1900: *fulvicornis*, *puncticollis*) and Bryant (1924: *bicolor*; 1959: *capensis*). Subsequent contributions, as Scherer (1983), did not modify substantially the taxonomic situation of this genus.

Through the examination of the typical series of all species and of a large amount of material preserved in African and European museums, or directly collected by me, I had the opportunity to see that some *Chirodica* species are instead belonging to subfamily Galerucinae or to different Alticinae genera.

So, the systematic position of all taxa hitherto attributed to the *Chirodica* genus is reviewed and discussed. Finally, a new diagnosis and new taxonomic arrangement of this flea beetle genus are supplied.

01-133

PATTERNS OF DISTRIBUTION IN DUTCH LEAF BEETLES OF THE SUBFAMILY GALERUCINAE (COLEOPTERA: CHRYSOMELIDAE)

R. Beenen

Marsburg 13, NL 3437 GN Nieuwegein, The Netherlands

One of the Dutch projects in the European Invertebrate Survey is the mapping of the distribution of Chrysomelidae. From the species of the subfamily Galerucinae preliminary maps are available.

The maps are based on the study of museum and private collections and on data made available by amateurs. Some conclusions already can be made.

Analysis of these maps give information on present and historical distribution patterns. The distribution patterns will be discussed. Causes for different patterns and fluctuations are partly natural and partly anthropogenic. An attempt will be made to correlate them to different life history strategies of the species.

Studies like these can give useful information for nature conservation strategies, both for the planning of locations as for the planning of management.

01-135

PROPOSAL FOR A NEW SUPRA-SPECIFIC CLASSIFICATION OF THE *CHRYSOMELA* GENUS AND THE OTHER RELATED GENERA (COLEOPTERA, CHRYSOMELIDAE)M. Biondi & M. Daccordi¹

Dipartimento di Scienze Ambientali, Università di L'Aquila, Coppito (AQ), Italy

¹ Museo Regionale di Scienze Naturali di Torino, Italy

A proposal for a new supra-specific classification of the *Chrysomela*, *Plagiodera*, *Linnaeidea*, *Gastrolina* and *Gastrolinoides* genera based on a select set of systematically significant morphological characters is presented. Every character considered is critically analysed and discussed within the subfamily Chrysomelinae.

On the basis of a bi-state character matrix and using multivariate statistical analyses, a "dendrogram of affinities" was obtained. Its interpretation has allowed to consider in new way the taxonomic arrangement of this genera complex.

Finally, to support the proposed hypothesis of classification an analysis of its biogeographical implications is supplied.

01-136

THE PUPAE OF CHRYSOMELOIDEA AND THEIR USE IN PHYLOGENY (COLEOPTERA)

M.L.COX

CAB International Institute of Entomology, London, UK

Pupae or published descriptions of representative species of the Cerambycidae, except Anoploderminae, Philinae and Oxypeltinae; the Bruchidae, except Eubaptinae, Kytorhininae and Rhaebinae; and all chrysomelids, except the Orsodacninae, Megascelinae and Aulacoscelinae were examined.

Only those characters not influenced by either larval or adult morphology were chosen as phylogenetic indicators.

The pupae of Cerambycidae and Chrysomelidae are similar in many respects. Cerambycid pupae differ since they sometimes have gin-traps, apparently lack antennal papillae, always have functional spiracles on abdominal segment 5, but lack them on abdominal segment 8. The pupae of Lepturinae most closely resemble those of the Chrysomelidae and share the following characters in common: frons, vertex, clypeus, labrum and mandibles setose; apices of femora with setae; tarsi setose; abdominal segment 9 either with a single urogomph or paired urogomphi; abdominal tergites usually distinctly sparsely setose; usually functional spiracles on abdominal segments 1-5 (rarely missing on abdominal segment 5); pupation in earthen cell. Bruchid pupae resemble those of leaf beetles, especially the Criocerinae. Both are often whitish; head, body and legs glabrous; antennae usually with papillae; often with short, paired, sexually dimorphic urogomphi; indistinct spiracles on abdominal segments 1-6, but an additional reduced pair on abdominal segment 7 in criocerines; pupation usually in a whitish cocoon, either thin papery or thicker, this apparently produced from a mouth exudate; cocoon usually on host plant or in soil. The Sagrinae-Donaciinae; Zeugophorinae-Megalopodinae-Palophaginae; Synetinae-Eumolpinae; Clytrinae-Cryptocephalinae-Chlamisinae-Lamprosomatinae; Chrysomelinae-Galerucinae-Alticinae; and Hispinae-Cassidinae are grouped together on pupal characters.

A discussion of the significance of pupal setae, urogomphi, position of pupation and 'silken' cocoon construction in the Chrysomeloidea is given.

01-138

THE TAXONOMIC SIGNIFICANCE OF RECENTLY DISCOVERED IMMATURE STAGES, HOST PLANTS AND LIFE HISTORIES OF ISCADIDA CHEVROLAT (COLEOPTERA: CHRYSOMELIDAE: CHRYSOMELINAE)

E. Grobbelaar

Biosystematics Division, Plant Protection Research Institute, Pretoria, South Africa

Since its inception in 1843, the southern African chrysomeline genus *IsCADida* Chevrolat has been associated with the genus *Timarcha* Latreille, regarded as its counterpart in the Holarctic Region. Currently these two genera are classified in the Chrysomelini: Entomoscelina and Timarchini: Timarchina, respectively, but this is not yet regarded as conclusive.

The adults, immature stages, host plants and life histories are well known for *Timarcha*, the only genus in the tribe Timarchini. The subtribe Entomoscelina contains 27 known genera, distributed throughout the world. Of the eight genera that occur in the Afrotropical region, seven are endemic to southern Africa. Nothing was known of the host plants of these endemic genera until recently, when intensive collecting resulted in the discovery of immature stages and host plants for three *IsCADida* species. Life cycles for these were unravelled in the laboratory.

IsCADida is now known to be associated with plants of the genera *Impatiens* (Balsaminaceae) and *Rhoicissus* (Vitaceae). Neither of these plants nor the Balsaminaceae as a whole have previously been recorded as hosts for the Chrysomelinae. Discovering the eggs of *IsCADida* allows an assessment of the extra-chorion ultrastructure of the Entomoscelina, the only subtribe in the Chrysomelinae for which it is unknown. Preliminary studies of the immature stages of *IsCADida* revealed the following interesting features: eggs are deposited singly on the ground or apparently on the host plant; larvae have mandibles with six teeth, distinct tubercles, eight abdominal spiracles, tarsal claws with an inner tooth, long setae and egg bursters associated with two long setae on the meso- and metathorax and first abdominal segment; three larval instars occur and the life cycle is either bi- or multivoltine. Most of these characters support the current placement of this genus in the Chrysomelini: Entomoscelina.

Results obtained in this study indicate that the characters of the immature stages and host plants of the ancestral genus *Timarcha* clearly differ from those of *IsCADida*. This supports the position of the latter genus in the more highly evolved tribe Chrysomelini.

01-137

STUDIES ON ASIAN ALTICINAE GENERA BASED ON WING VENATION, GENITALIA, AND METAFEMORAL SPRING (COLEOPTERA: CHRYSOMELIDAE)

D. G. Furth¹, K. Suzuki²

Department of Entomology, Smithsonian Institution, Washington, D. C. USA - I

Department of Biology, Faculty of Science, Toyama University, Gofuku, Toyama, Japan - 2

As part of a continuing study on the establishment of true generic groups in this largest chrysomelid subfamily, four independent internal character systems were studied (i.e. hind wing venation, male and female genitalia, and the metafemoral spring). The authors have studied these character systems in over 60 Asian genera, primarily from eastern Asia and adjacent areas. Many genera are associated preliminarily based on morphological similarity of the character systems. Some of these associations support the traditional catalogue arrangement (i.e. presumed close relatives) (e.g. *Sangariola* and *Laboissierea*, or *Hyphasis* and *Hemipyxis*) while others do not (e.g. *Eudolia*, *Garuda* and *Licyllus*, or *Phygasia*, *Liprus*, *Lipromorpha*, and *Pseudoliprus*). Such studies are combined with previous research to show other similarities and differences among genera from other regions. These studies will be used to establish phylogenetic relationships among genera in the future when a significant proportion of the subfamily has been studied.

01-139

THE ROLE OF CHEMICAL SIGNALS FOR PREDATORS AND PARASITES OF EGGS AND LARVAE OF GALERUCINAE (COLEOPTERA: CHRYSOMELIDAE)

M. Hilker¹, A. Köpf², T. Meiners¹

1 Freie Universität Berlin, Institut f. Zoologie, Haderslebenerstr. 9, D-12163 Berlin, Germany - 2 ETH Zürich, Institut f. Terrestrische Ökologie, Experimentelle Ökologie, ETH-Zentrum-NW, Clausius-Str. 25, CH-8092 Zürich, Switzerland

Eggs and larvae of leaf beetles of the subfamily Galerucinae, tribe Galerucini, are known to contain anthraquinones and anthrones, which were proved to act as feeding deterrents against ants and birds. However, the presence of these compounds does not prevent the eggs from parasitism. Eggs of *Galeruca tanacetii* and *Galerucella* species are often heavily attacked by the chalcidoid wasps *Oomyzus galerucivorus* and *O. gallerucae*, respectively. Our studies on the role of chemicals in host selection of these parasitoids will be presented. When investigating host finding, the attractivity of volatiles from the following sources were studied in olfactometer bioassays: gravid leaf beetle females, plants with host eggs, undamaged plants, plants damaged by feeding leaf beetles, and faeces of the beetles. Host recognition behavior of the parasitoids is indicated by frequent antennal drumming on the surface of host eggs. Our studies aimed on the isolation, characterization and identification of (extra)chorion compounds inducing antennal drumming. Host acceptance as indicated by oviposition of the parasitoid might be mediated by compounds within the host eggs. GC-MS analyses revealed that anthraquinones and anthrones are not located at the outside of the eggs, but are only present inside. The parasitoid does not transfer these compounds from the larval to pupal stage: anthraquinones and anthrones were only found in the excreta of the last larval instar, but not in pupae and adult parasitoids. The role of chemicals for predators and parasites of the galerucine juvenile stages investigated will be balanced against the possible importance of physical cues.

01-140

HOST-PLANTS OF THE ENTOMOSCELINA REITTER
(COLEOPTERA CHRYSOMELIDAE CHRYSOMELINAE)

P. Jolivet

67 Boulevard Soult, F-75012 Paris, France.

The Entomoscelina, according to Daccordi (1994) integrating the Phyllocharina, actually comprise 29 genera divided into 3 sections. It is very difficult to find clear cut common characters using only the external morphology of the adults. In addition, very little is known regarding the feeding habits and the larvae. Some genera are orophilous and nocturnal, some feed on vines and bushes, other live near the ground or on herbs at the Southern tips of Australian, African and American continents. Probably, the subtribe Entomoscelina is artificial and composed of many divergent taxa. The food-plants of 14 taxa are examined here and as expected they do not have any plant taxa in common: Vitaceae, Lamiaceae, Brassicaceae, Urticaceae, Scrophulariaceae, Bignoniaceae, Pittosporaceae, Verbenaceae. However, the related food-plants within the Scrophulariaceae and the Verbenaceae for *Chalcomera* s. lat. confirms the unity of the genus through South-East Asia, Australia and New Zealand. Three genera feed on Verbenaceae: *Phyllocharis*, *Didosoma* and *Phola*.

01-142

BIOLOGY AND BEHAVIOR OF BRAZILIAN LEAF BEETLES
ASSOCIATED TO SOLANACEOUS PLANTSLenice Medeiros¹, David N. Ferro² & Agenor Mafra-Neto³

¹Departamento de Biologia e Química, Universidade de Ijuí, RS 98700 Brazil; ² Department of Entomology, Fernald Hall, University of Massachusetts, Amherst, MA 01003 US, ³Department of Entomology, 411 Science II, Iowa State University, Ames, IA 50011-3222, USA.

We monitored the population dynamics and behavior of several chrysomelids associated with native solanaceous plants of Ijuí, RS, Brazil. *Platyphora quadrisignata*, *P. fasciatomaculata*, *P. vinula*, *Gratiana* sp. 1, *G.* sp. 2, *Metriorhiza elatior*, *Charidotella* sp., *Cistudinella* sp., *Lema reticulosa*, *L. apicalis*, and *L.* sp were studied. All were monophagous, except *P. vinula*, which was associated with both *Solanum megalochiton* and *S. sanctae-catharinae*. The chrysomelids diapaused during the winter (July and August). From October to December, larval recruitment peaked; this coincided with low parasite and predator population densities. Eulophidae and Asopinae caused high mortality in Criocerinae eggs and larvae, respectively; Tachinidae and Asopinae caused high mortality in Chrysomelinae and Cassidinae larvae. Predation and parasitism of immatures increased throughout the season, peaking during January. Certain reproductive strategies of Criocerinae and Chrysomelinae may have evolved to ensure protection against the ubiquitous presence of egg parasites and predators. The Criocerinae *Lema apicalis*/*Lema reticulata* (one species?) laid egg masses in a clumped distribution creating hard-to-find, but dense local populations. In contrast, the Chrysomelinae were all larviparous, bypassing the less protected sessile egg stage. Chrysomelinae larvae are protected by cycloalexic behavior or by shifts in foraging period from days to nights. Criocerinae larvae are protected by a coat of regurgitate and feces coupled with cycloalexic behavior. Cassidinae larvae are protected by a highly mobile shield made of exuvia and feces. Although well protected, the Chrysomelids in Ijuí still suffered large losses of immatures to parasites and predators.

01-141

PHYLOGENETIC STUDIES ON THE LARVAE
OF THE CHRYSOMELIDAE (COLEOPTERA)

J. E. Lee

Department of Biology, Andong National
University, Andong, Kyungbuk, Korea

The larvae treated in this study include 77 species in 45 genera and 16 subfamilies. The phylogenetic relationships among subfamilies were inferred on 34 characters of the larvae by the Wagner tree method on a computer after the evaluation of every character and the inference of its polarity.

The cladogram obtained by this method suggests the phylogenetic position of the Orsodacninae and Megalopodinae on a first branch as sister taxa from the rest. Next branch is the Bruchidae, which should be treated as a subfamily of the Chrysomelidae. The Donaciinae constitute the third branch. The remaining subfamilies can be divided into two phylogenetic groups, one comprises the Zeugophorinae, Criocerinae, Synetinae, Eumolpinae, Chlamisinae, Clytrinae, Cryptocephalinae, and Lamprosomatinae, while the other includes the Alticinae, Galerucinae, Chrysomelinae, Cassidinae and Hispinae.

01-143

IS HOST-PLANT DERIVED CHEMICAL DEFENSE IN
CHRYSOMELA AN EVOLUTIONARY CONSTRAINT?J.M. Pasteels, Ph. Soetens, D. Daloze⁽¹⁾

Laboratoire de Biologie animale et cellulaire - ⁽¹⁾Laboratoire de Chimie Bio-organique, Université Libre de Bruxelles - Belgium

Most *Chrysomela* species feed on Salicaceae and their larvae secrete in their defensive glands salicylaldehyde derived from plant phenolglucosides (mainly salicortin). This host dependence for defense does not constitute an insurmountable evolutionary constraint for further shifts on non-salicaceous plants.

Species of the subgenus *Microdera* feed on *Betula* and *Alnus*. Molecular phylogenies (in coll. with T. Hsiao) indicate that feeding on non-salicaceous plants is a derived condition within the genus.

Comparative analysis of the secretion of selected beetle species fed on *Salix* spp. devoid of phenolglucosides in their leaves (in coll. with S. Neuvonen) demonstrated that the larvae still produce a defensive secretion, which was reduced in volume and contained no or little amounts of salicylaldehyde. This contrasts with *Phratora vitellinae*, also secreting host-derived salicylaldehyde, which does not produce anymore a defensive secretion when fed on plants devoid of phenolglucosides. It remains to discover if the flexibility in defense of *Chrysomela* spp. is due to their ability to utilize a larger spectrum of plant precursors or to a capacity of autogenous synthesis. It is suggested that the selective pressure of specialist natural enemies could induce shifts on plants without phenolglucosides, even though defense against generalist predators is reduced.

01-144

THE CYTOTAXONOMY AND EVOLUTION OF CHRYSOMELINAE
LEAF BEETLES REVISITED.

E. Petitpierre
Laboratori de Genètica, Facultat de Ciències,
Universitat de les Illes Balears, Palma de
Mallorca, Spain.

Twenty-two species of Chrysomelinae mostly from Europe, have been recently examined to increase the sample of cytogenetically known taxa of the subfamily to some 200 species. Eight species of *Chrysolina*, three of each *Oreina*, *Cyrtonus* and *Phratora*, two of each *Iscadida* (from S. Africa) and *Chrysomela*, and one of *Ambrostoma* (from NW China), have been analyzed. Among these data, *Oreina viridis* (Duft.) has shown the ancestral meioformula of 9+Xyp (2n=20), the most frequent in the plesiomorphous genus *Timarcha*, which stands off with regard to the other species of *Oreina*, all having 11+Xyp (2n=24). The possible chromosomal evolution of *Chrysolina* subgenus *Stichoptera* is discussed. The location of *C. fuliginosa* (Ol.) and *C. lepida* (Ol.) in the subgenus *Allochrysolina* is also proved since they share the meioformula of 20+Xyp (2n=42). Moreover, we point out the intermediate karyological derivation of *Iscadida* and most *Cyrtonus* with 12+Xyp (2n=26) and 13+Xyp (2n=28) respectively, and the advanced position of *Chrysomela* and *Phratora*, all whose species have 16+Xyp (2n=34). The subfamily has three main steps of chromosomal evolution set up by the the haploid numbers of: 10 in most taxa of *Timarcha*, in *Cosmogramma decora* and *Oreina viridis*, 12 in most *Chrysolina*, *Calligrapha*, *Gonioctena* and paropsines, and 17 in *Phaedon*, *Chrysomela*, *Phratora*, etc., which agrees with some other features of phylogenetic value.

01-146

COMPARATIVE INTERNAL HEAD CAPSULE MORPHOLOGY IN
CHRYSOMELIDAE (COLEOPTERA)

M. SCHMITT

Zoologisches Forschungsinstitut und Museum Alexander
Koenig, Adenauerallee 160, D-53113 Bonn, Germany

Cuticular surface structures of the inner face of head capsules have not found much attention in insect morphology and phylogenetics up to now. Head capsules from about 20 species out of 8 leaf beetle subfamilies (Crucidae, Donaciinae, Sagrinae, Cassidinae, Clytrinae, Chrysomelinae, Galerucinae, Alticinae) and Bruchidae have been studied after maceration by means of a Stereo-Electron-Microscope. The diverse inner surface patterns yield promising characters for phylogenetic analysis.

01-145

TOPOGRAPHIC AND GENETIC STRUCTURE IN AN ALPINE LEAF BEETLE: *Oreina cacaliae* (COLEOPTERA, CHRYSOMELINAE).
M. ROWELL-RAHIER AND S. KNOLL,
INSTITUT DE ZOOLOGIE, EMILE ARGAND 11, UNIVERSITE DE NEUCHÂTEL, CH-2007
NEUCHÂTEL, SWITZERLAND

Herbivorous insects with their strong association to host plants often show very patchy distributions. On what scale "gaps" between suitable host plants or host plant patches are barriers to gene flow and affect population structuring depends on the dispersal of the species. Leaf beetles (Coleoptera: Chrysomelidae) feed as larvae and adults on the same host plants. Both, larvae and adults, often show an aggregative distribution and a low vagility. In willow feeding leaf beetles genetic differentiation was found already between beetles feeding on neighbouring trees. We were interested whether such a small scale differentiation can also be found in herbivores feeding on a less permanent resource. Therefore we studied the spatial population structure of *Oreina cacaliae*, an alpine species feeding on herbaceous host plants (*Adenostyles*, *Senecio*, *Petasites*). To gain information about population sizes and movement rates we observed marked beetles at three different sites over one season. Allozyme electrophoresis of 25 presumptive loci reveals for *O. cacaliae* high polymorphism, high inbreeding rates and considerable genetic variation at a very small scale. Significant FST values are found between groups only some hundred meters apart. This is in agreement with results from mark and recapture studies, which give high recapture rates and small movement rates (max. 3m/day). Such a local differentiation could not be explained by host plant use or by different altitudes. Geographic distances, however, are at larger distances (>10 km) well correlated with genetic distance. Obviously limited movement capabilities lead to either an extremely local differentiation (possibly in combination with strong habitat specificity) or to non random mating. It could be that we sampled family groups or closely related individuals who do not migrate.

01-147

THOUGHTS ON GALERUCINE ZOOGEOGRAPHY (COLEOPTERA,
CHRYSOMELIDAE)

Hans Silfverberg

Finnish Museum of Natural History, Division of Entomology, P.O.Box 17,
FIN-00014 Helsingfors, Finland.

Galerucinae is one of the largest subfamilies within Chrysomelidae, with a worldwide distribution, but only a few of its genera are represented in more than one zoogeographical region. The subfamily has been further subdivided into tribes, and they into subtribes and genus groups; among these categories we already find some that are restricted to one region, while others are widely distributed. The subfamilies of Chrysomelidae seem mainly to have differentiated during the Jurassic period, when the continents were united in the Pangean supercontinent. When Pangea began to break up during the Cretaceous period, the Galerucinae were apparently already widely distributed and differentiated. Among the tribes Galerucini and Hylaspini seem to have a Laurasian origin, Metacyclini a West Gondwanan, and Luperini gives the appearance of already having been widely distributed at an early date. On the Indian subcontinent the Galerucinae are quite numerous and differentiated in the northern parts, particularly in the Himalaya. Further south there is a much lower number of genera, and almost all these genera are widely distributed. A large part of the Indian genera are also found in China and South-East Asia. Probably the Indian fauna is derived from the Eurasian continent; any Galerucinae living on the Indian plate before its drift to the north can be assumed to have perished in the Deccan volcanism at the end of the Mesozoic era. Our knowledge of Galerucine phylogeny is still insufficient for a definite zoogeographical analysis. For one thing the position of the New Zealand genera (*Adoxia*, *Allosterna* and *Bryobates*) should be ascertained, but many other questions also remain. Some of the recognized genera appear to be rather heterogenous, and we need a synthesis of studies from various regions.

01-148

HOST-PLANT SELECTION IN TWO SALICACEAE SPECIALISTS, *PHRATORA VITELLINAE* AND *PH. TIBIALIS*

Ph. Soetens, J.M. Pasteels

Laboratoire de Biologie animale et cellulaire, Université Libre de Bruxelles, Belgium

Food plant preferences in nature and in the laboratory were studied for two species, *Phratora vitellinae* and *Ph. tibialis*. Ten different potential host plants were included in this study. Five willows: *Salix alba*, *S. babylonica*, *S. caprea*, *S. fragilis* and *S. purpurea* and five poplars: *Populus deltoides*, *P. deltoides* x *nigra*, *P. nigra*, *P. trichocarpa* and *P. trichocarpa* x *deltoides*. Phenolic glucosides, mono- and disaccharides content, as well as trichome density of the leaves were quantified.

Ph. vitellinae is oligophagous on plants with leaves rich in phenolic glucosides and with low trichome density. *Ph. tibialis* is monophagous in the field on *S. purpurea*, but in laboratory preference tests, *S. babylonica* is also accepted as a food-plant.

Ph. vitellinae larvae are able to use plant phenolic glucosides (salicortin and salicin) as precursors of defensive secretion but not tremulacin and tremuloidin. Salicortin in synergy with sucrose had a strong phagostimulatory effect on the adults of *Ph. vitellinae* but a more complex mixture of phenolic glucosides and sugars is even more stimulant.

Chemical defense of *Ph. tibialis* larvae is not host-derived but autogenous. In adults, only the mixture of salicortin and sucrose is found to be stimulant. This result does not explain the monophagy of the species.

In both species, flavonoïds present in willow leaves (7-O-eriodictyol glucoside, 7-O-luteoline glucoside and 7-O-naringenine glucoside) did not stimulate nor inhibit feeding in laboratory tests.

01-149

THE DISTRIBUTION OF THE SENSILLA ON THE HIND WINGS OF THE FAMILY CHRYSOMELIDAE (COLEOPTERA) AND ITS SYSTEMATIC SIGNIFICANCE

K. SUZUKI, C. TANAKA

Department of Biology, Faculty of Science, Toyama University, Toyama, Japan

The distribution of the sensilla on the hind wings of the family Chrysomelidae (Coleoptera) and its systematic significance. The sensilla chaetica (s.c.) on the so-called recurrent vein (Rv), which consists of M1+2, M3+4, and m-m, of the hind wings in 348 chrysomelid species of 181 genera belonging to 19 subfamilies, was studied (Table). The variability and the systematic significance of this new character are discussed.

Subfamily	No. gen.	No. Spec.	No. M s.c.
Orsodacninae	1	2	1~ 2
Zeugophorinae	1	3	0~ 2
Megalopodinae	4	4	2~10
Aulacoscelinae	2	6	1~ 7
Sagrinae	11	19	0~ 8
Donaciinae	4	22	1~ 6
Criocerinae	4	15	0~ 9

DIVERSIFICATION OF FECAL SHIELD-BEARING LEAF-BEETLES (CHRYSOMELIDAE) PROMOTED BY HOST PLANT-DERIVED CHEMICAL DEFENSE

F. V. Vencel¹, T. C. Morton²

Department of Neurobiology and Behavior, State University of New York at Stony Brook, Stony Brook, NY USA - 1

Department of Entomology, Pennsylvania State University, University Park, PA USA. - 2

Predators and parasitoids may represent a major selective force that promotes diversification in herbivorous insects. Mechanisms by which this might occur are not well understood but dietary specialization, enforced by predation pressure, appears to be a requisite condition. Larvae of criocerine leaf beetles (*Lema*, *Neolema*, *Oulema*), and of an alticine (*Blepharida*), due to the anatomical oddity of a dorsal anus, deposit feces that form a 'shield' on top of their bodies. Appropriately host-derived fecal shields are repellent to ants and function as a defense. Extraction and fractionation of plant and frass, followed by the ant bioassay of fractions, revealed that larvae expropriate the secondary chemicals of their hosts and incorporate them, apparently with little transformation, into their frass. Furthermore, larvae concentrate specific host compounds 1000 fold. A repellent plant terpenoid (mol. wt. 296) was isolated from all shields and a complex of steroidal glycoalkaloids was isolated from shields of the solanaceous feeders.

The simple terpenoid defense is augmented in larvae feeding on more chemically complex hosts. The criocerine clade colonizing the more complex solanaceous hosts is derived and is twice as diverse as the sister taxon that retained the ancestral hosts in the Commelinaceae.

Chemical complexity of the shield defense with respect to targeting and efficacy against a suite of enemies (i.e. does a more complex shield afford protection against a broader spectrum of enemies?) and its relationship to host specialization and enhanced beetle diversification will be examined to test the predator-free space hypothesis.

01-151

GENETIC VARIABILITY IN MONO- AND OLIGOPHAGOUS CHRYSOMELID BEETLES AT VARIANCE WITH THE NICHE-WIDTH VARIATION HYPOTHESIS.

P. Verdyck

Department of Entomology, Royal Belgian Institute of Natural Sciences, Brussels, Belgium

The niche-width variation hypothesis (Van Valen, 1965) predicts a positive correlation between niche breadth and genetic variability. A group of animals ideally suited for testing the hypothesis is found in the phytophagous insects, in which the niche is mainly determined by the number of hostplant species they live on. In this study we compare genetic variability between mono- and oligophagous *Phyllotreta* species (Coleoptera : Chrysomelidae).

In total 36 populations belonging to 10 different *Phyllotreta* species were analysed for 10 loci using allozyme electrophoresis. Genetic variability was studied using four different criteria : average number of alleles per locus, % of loci polymorphic, observed heterozygosity and expected heterozygosity under Hardy-Weinberg conditions. For each of the measures a Mann-Whitney U test was used to check for significant differences between mono- and oligophagous species. For all the genetic variability measures used, monophagous species show a significantly higher genetic variability compared to the polyphagous species. This is at variance with the niche-width variation hypothesis. Two alternative explanations are possible, the first concerning the limited availability of hostplants in monophagous *Phyllotreta* species, the second concerning the relation between oligophagous species and agricultural crops.

Van Valen, L. 1965 *Am.Nat.* 99 : 377-390.

01-152

HOST PLANT SELECTION OF PHYLLOTRETA SPECIES.
THE CASE OF PHYLLOTRETA VITTULA (REDT.)

K. Vig

Department of Natural History, Savaria Museum,
Szombathely, Hungary

Nearly all species of Phyllotreta feed on crucifers or on the plants of related genera of Resedaceae and Capparaceae. The one known exception is Phyllotreta vittula (Redt.) which feeds on grasses and cereals but, however, accepts various crucifers too. Feeding responses of adults were evaluated by means of leaf disc test. Significant differences were found between responses to eight plants of Gramineae and five crucifer plants. Strong preference of grasses was detected. The origin of this preference provides material for evolutionary studies on the host plant selection not only of Phyllotreta species, but phytophagous insects as well. Further studies are needed to clarify the biochemical background of the host plant selection of Phyllotreta vittula (Redt.).

01-154

HOST PLANTS AND THE DIVERSIFICATION OF
NEOTROPICAL TORTOISE BEETLES (COLEOPTERA:
CHRYSEMELIDAE: HISPINAE)

D. Windsor, H. Barrios

Smithsonian Tropical Research Institute, Balboa-Ancon, Panama

Phylogenetic relationships among tribes and genera of Neotropical tortoise beetles ("cassidoid Hispinae", sensu Borowiec) are examined using a cladistic analysis of 85 morphological and behavioral characters. Modern host plant associations, mite associations, habitat preferences and antipredator defenses are used to infer historical aspects of diversification in these leaf-feeding beetles.

01-153

DISTRIBUTION PATTERNS OF CHRYSEMELID BEETLES IN
CENTRAL AFRICAN FORESTS

Thomas Wagner

Zoologisches Forschungsinstitut und Museum Alexander Koenig,
Adenauerallee 160, D-53113 Bonn, Germany

In several types of forests in Central Africa, the arthropod fauna of selected tree species was investigated using insecticidal fogging technique. In a gallery forest in East Rwanda, on eight trees of Teclea nobilis (Rutaceae), Chrysomelids reached 42% of all beetle specimens. Especially a few species of Alticinae were highly abundant, and most of them found on all trees. In a mountain rain forest in West Rwanda, on nine trees of Carapa grandiflora (Meliaceae) Chrysomelids, predominantly Galerucinae, were much less abundant and the frequency of the species was lower. In a semi-deciduous forest in North-West Uganda 64 trees assigned to four species (Cynometra alexandri (Caesalpiniaceae), Rinorea ardisiifolia (Violaceae), Trichilia rubescens (Meliaceae), and Teclea nobilis) were fogged. Eumolpinae formed the bulk of Chrysomelids. The diversity of leaf-beetles was relatively equal on the different tree species in primary as well as in secondary forest, but differs stronger between these two forest types.

01-155

REDUCTIONS AND NEW INVENTIONS DOMINATE
OOGENESIS OF STREPSIPTERA

J. Büning

Zoological Institute 1, University of Erlangen, Erlangen, Germany

The endoparasitic life of strepsipterans, especially of larviform females, reduces to great extent external and internal organs. Light and electron microscopic investigation of ovaries confirm this general feature:

1) Somatic tissues of ovaries like outer envelope, the ovary ligament, the tunica externa of ovarioles, the terminal filament, somatic apical cells, prefollicular cells, the pedicel and the lateral oviduct are reduced totally. 2) A previtellogenic growth phase of oocytes is absent. Growth of euplasm is shifted into the phase of cluster mitoses, before morphological differentiation of oocytes becomes apparent. 3) Nurse cells remain diploid and their cell membranes degenerate during onset of vitellogenesis. 4) Vitellogenesis is reduced, vitellin and fat vacuoles contribute to only 50% of the final volume of the egg. 5) Chorionogenesis is reduced and produces a very thin chorion.

However, some features of normal development remain and allow to consider the type of ovary as strongly deviated, but nevertheless, polytrophic meroistic: 1) Germ cells undergo synchronized, incomplete divisions which follow the 2ⁿ rule: one sibling cell gets all old intercellular bridges, the other none. 2) During the division program, all cystocytes form a rosette with a polyfusome. 3) Only one cell of each cluster will be determined as oocyte, all others serve as nurse cells. 4) Each cluster is surrounded by some somatic cells, serving as follicle cells.

New inventions are 1) Fission of clusters during the phase of cluster mitoses; thus, the amount of oocytes raises tremendously. 2) Protection of the germinal vesicle, while nurse cell nuclei will degenerate in the same cytoplasm.

Supported by DFG grant to J.B

01-156

SPERM ULTRASTRUCTURE IN STREPSIPTERA.

M. Carcupino¹, J. Kathirithamby², M. Mazzini¹.

1)Department of Environmental Sciences, University of Tuscia, Viterbo, Italy. 2) Department of Zoology, University of Oxford, Oxford U.K.

In the last few years, the fine structure of the spermatozoon in five species of Strepsiptera, namely *Xenos moutoni*, *X. vesparium* (Stylopidae), *Elenchus tenuicornis* and *E. japonicus* (Elenchidae) and *Halictophagus chilensis* (Halictophagidae) has been examined.

The spermatozoon of all species studied so far is a filiform cell in which the common two parts, sperm head and sperm tail, are recognizable. The sperm head consists of a monolayered acrosome resting on an elongated nucleus which contains an eccentric portion of uncondensed chromatin, except in the sperm of *X. vesparum*. The sperm tail shows a 9+9+2 axoneme flanked by two mitochondrial derivatives. The connecting piece between the head and the tail is characterized by a bilocular head-tail junction.

In spite of this general organization, the spermatozoon ultrastructure of Strepsiptera has taxonomic value showing features which can be considered as generic or specie-specific. The spermatozoon of the two species of Stylopidae has some peculiar characters such as, a brush-like glycocalyx, U-shaped mitochondrial derivatives, while, sock-shaped mitochondrial derivatives are typical of the two species of Elenchidae examined. In addition, the bilobate acrosome of *X. moutoni*, the very long nucleus without the eccentric portion of uncondensed chromatin as well as the U-shaped mitochondrial derivatives without paracrystalline material of *X. vesparum*, may be considered as specie-specific characters.

01-158

LITTLE BUGS THAT LIVE IN SMALLER BUGS AND SO AD INFINITUM
J. Kathirithamby

Department of Zoology, University of Oxford, Oxford, U.K.

Intercellular procaryotes in mycetocytes, follicular cells and mature eggs have been described in a wide variety of insects and here the presence of *Wolbachia*-like organisms in five species of Strepsiptera is presented. This is the first report of the presence of micro-organisms in Strepsiptera. *Wolbachia* has been recorded in the hosts of Strepsiptera, namely Hymenoptera, Diptera, Orthoptera, Homoptera and Hemiptera.

These intracellular associations have major consequences for both bacteria and host, and in this study three organisms are involved: bacteria, host (strepsipteran), and superhost (host of strepsipteran). Cytoplasmically inherited micro-organisms are responsible for a number of reproductive disorders in insects and other arthropods. In Strepsiptera the micro-organisms are present in both sexes during the larval stages, but only in the neotenic female and not the male adult or pupa. The micro-organisms are mainly present in the germ cells/oocytes/eggs in the female, which indicates that the micro-organisms might be maternally transmitted. In the larval stages of the male the micro-organisms are present in the gut region.

In one system of Strepsiptera studied so far - the Delphacidae and their strepsipteran parasite *Elenchus*, the evidence indicates that there might be horizontal transmission.

01-157

SYSTEMATICS OF NORTH AMERICAN STREPSIPTERA, WITH NOTES ON THE BIOLOGY OF *CAENOCHOLAX FENYESI*

J.L. Cook, S.B. Vinson and R.E. Gold

Department of Entomology, Texas A&M University, College Station, TX, U.S.A.

Systematics of North American Strepsiptera reviewed for the first time since Bohart's revision in 1941. Bohart synonymized ten *Xenos* species into two currently recognized species. Evidence is presented that one or more of these species are valid and should not have been synonymized. The genus *Stichotrema* is reported from the United States for the first time. A female and triungulin of *Caenocholax fenyesi* Pierce are described. This is the first record of a female in this genus. Females have been described for only ten percent of known species of Myrmecolacidae.

The biology of *C. fenyesi* and the relationship to its known host, *Solenopsis invicta*, are discussed. The distribution of *C. fenyesi* suggests that *S. invicta* is not its only host and this relationship is possibly the result of a recent host switch in the United States. Stylopization levels are very low in colonies of *S. invicta* in the United States. This may be a result of the proposed recent host switch or the scarcity of its female host. A behavior change resulting from stylopization is documented. A behavior change occurs in *S. invicta* in late stages of strepsipteran development, causing abnormal behavior, including a loss of normal social behavior.

01-159

FACTORS AFFECTING THE REPRODUCTIVE POTENTIAL IN STREPSIPTERA

Y. Maeta

Laboratory of Insect Management, Faculty of Life & Environmental Science, Shimane University, Matsue 690, Japan

In phoretic insects, the successful life cycle is maintained depending on the probability of the first instar larvae which can attain to the proper hosts. They are well known to produce enormous number of eggs throughout their long life span. Strepsiptera has the highest reproductive potential in Insecta except some social insects such as termites, etc. It is not exaggerated to say that female stylopids are ovipositional machine.

The egg complement (total number of eggs produced in a maternal body) greatly differs among the species of Strepsiptera, maximum was found in *Strichotrema dallatorreanum* (750,000 eggs) and minimum in *Triozocera macrosotyti* (984 eggs). The difference of egg complements in Strepsiptera might be arisen from both the external-factors (life type of hosts, etc.) and the internal-factors (species and size of hosts, sex of hosts, number of stylopids parasitized on a single host, etc.). The author analyzed factors to determine the egg complement in various Japanese species of the following genera, *Triozocera* and *Blissoxenos* (Corioxenidae); *Halictophagus* (Halictophagidae); *Elenchus* (Elenchidae); *Stichotrema* (Myrmecolacidae); *Pseudoxenos*, *Xenos*, *Paraxenos*, *Halictoxenos* and *Stylops* (Stylopidae). The results were generally concluded as follows, irrespective of their phylogenetic relation: 1) Egg complement was larger in those species of which hosts were gregariously inhabiting in a very limited area or conspicuously visiting flowers than that in those species of which hosts are weakly having above two traits. 2) Egg complement was reduced largely by the parasitization on small-sized hosts and male hosts, as well as by polyparasitism as compared with that obtained from the parasitization on large-sized hosts and female hosts, as well as by monoparasitism.

01-160

THE FIRST INSTAR LARVAE OF THE STREPSIPTERA

H. Pohl

Institut für Zoologie, Technische Hochschule, Darmstadt, Germany

Current investigations with scanning electron microscopy techniques (SEM) include first instar larvae of all until now known families of the Strepsiptera, except Callipharixenidae and Bohartillidae. Semi thin sections of two taxa were examined with light microscopy.

The prognathus head is flat on its ventral, convex on its dorsal side. In ventral view head appendages are visible. They are the maxillae and the labium, each bearing paired palps. In several taxa the labial and maxillary palps are almost reduced. Antennae are absent. The fusion of lateral and ventral margins of the maxillae and labium with ventral margins of the head capsule produces a preoral cavity. This cavity contains the mandibles and, at its caudal side the primary or inner mouth opening. The secondary or outer one is at the apex of the front end of the head. A tentorium is present. In lateral view 2–6 stemmata are visible on each side. The so called “Antennenfelder” (“antenna areas”), are paired sensory pits, which are not present in all taxa. In the apomorphic ones they are reduced to very small pits. A basic pattern of setae is varied in the several families.

The legs consist of coxa, trochanterofemur, tibia, and tarsus. The tarsi of the first two pairs of legs are mostly modified into suction pads, the hind ones are rod shaped. The intercoxal sternites are very variable.

The abdomen is 10-segmented, with two long movable caudal setae. These are homologous to cerci. The plesiomorphic ones, characterized by fused terminal segments, can jump. The apomorphic ones, with free terminal segments lost this capability.

Evolutionary trends that are visible in the first instars are discussed.

01-162

NOVEL MORPHOLOGICAL CHARACTERS AND THEIR IMPACT ON CURCULIONOID CLASSIFICATION

Christopher H. C. Lyal

Department of Entomology, The Natural History Museum, Cromwell Road, London SW7 5BD, England.

One of the areas of classification of the Curculionoidea which is exciting most interest is in the ‘higher’ weevils, particularly among those subfamilies of Curculionidae which might be sister-group to the Scolytinae. Setting aside disputes over ranking of the subfamilies/tribes concerned, there are few data which enable cladistic resolution of this part of the Curculionidae. The stridulatory mechanisms employed by weevils, and the presence and structure of specialised organs along the anapleural suture, ‘sclerolepidia’ both shed light on the classificatory problems in question, as well as being potentially valuable in other areas of weevil classification.

01-161

FROM MOLECULES TO EMBRYOS: INSIGHTS ON THE PHYLOGENY AND EVOLUTION OF THE STREPSIPTERA.

M. F. Whiting.

Department of Entomology, American Museum of Natural History, New York, NY USA.

Phylogenetic relationships among the holometabolous insect orders were inferred from cladistic analysis of nucleotide sequences of 18S ribosomal DNA (83 exemplars), 28S rDNA (52 exemplars) and morphological data (176 characters). Twenty insect outgroups, all holometabolous insect orders, and six strepsipteran species were included in this study

Cladistic analysis supports a sister-group relationship between Strepsiptera and Diptera (=Halteria). This relationship is well-supported, as indicated by large Bremer support values, large branch lengths, and a lack of sensitivity to the parameters used in phylogenetic reconstruction. Long-branch attraction does not appear to influence this result because the strepsipteran-dipteran branch lengths and sequence divergences are comparable to other well-supported monophyletic groups included in the analysis.

Homeotic transformation of strepsipteran thoraces is suggested as a hypothesis to account for the presence of halteres on different thoracic segments in Diptera and Strepsiptera. The progress of studies underway to determine the pattern of homeotic gene expression in strepsipteran embryos is presented.

01-163

SOLVING THE RIDDLE: COMBINING LIFE-HISTORY ANALYSIS AND MORPHOLOGICAL COMPARISON IN WEEVIL PHYLOGENETICS

S. vdM. Louw

Department of Zoology & Entomology, University of the Orange Free State, 9300 Bloemfontein, South Africa

Albeit that the phytophagous feeding habit of weevils (Coleoptera: Curculionoidea) is in many instances manipulated for bio-control practices against invasive alien plants and the pollination of beneficial plants, it is the magnitude of their destruction of crops and other cultivated plants that label them as one of the most economically important insect groups. Despite the fact that the higher classification of the weevils has now been sorted out, the group is still rife with many unresolved phylogenetic “grey-areas” on the lower taxonomic levels. Many regional and a few world revisions of certain weevil groups have been cladistically researched, but all in all the current knowledge of weevil faunistic relationships on the generic-specific level across continents is still in disarray. It is now necessary, as the next phase in the weevil classification saga, that this be addressed on an inter-continental basis. This paper discusses the value of considering bio-ecological traits, i.e. life-history studies and host-plant associations in conjunction with basic alpha taxonomic morphological comparison to determine certain weevil relationships and ultimately reach phylogenetic solutions. Female genitalic morphology of the Brachycerinae (Curculionidae), host associations of the Urodontinae (Anthribidae) and life-history analysis of the Somatodini, Entimini, Microcerini, Brachycerini and Rhytirhinini (Curculionidae: Brachycerinae) serve to demonstrate the point.

01-164

THE GENUS *PODAPION* RILEY, 1883 IN THE OLD WORLD: A NEW SPECIES AND BIOGEOGRAPHICAL IMPLICATIONS (COLEOPTERA: APIONIDAE: APIONINAE)

M. A. Alonso-Zarazaga

Departamento de Biodiversidad y Biología Evolutiva, Museo Nacional de Ciencias Naturales, CSIC, Madrid, Spain

The discovery of a new species of the genus *Podapion* Riley, 1883 in the mountains of Central Spain poses a very interesting biogeographical problem, already aroused with the discovery that the species described originally as *Magdalis mariae* Formánek, 1911, belongs to this genus too (Korotyaev, 1993). The generic description is amended, the new species *P. baenai* is described and figured and a key to the three known species is given.

Two different hypothesis on the phylogenetic history and the zoogeography of the species involved are presented. The first scenario shows a hypothetical common ancestor of the genus living in both Western and Eastern North America and Europe (age: Jurassic to Middle Cretaceous: not later than 95 MY), whose populations became split by the opening of the North Atlantic Ocean and began to diverge both genetically and morphologically. The American population split up again into two populations (western and eastern) because of the severe cooling of climate during the Oligocene and Miocene, and the formation of the dry pasture belt across Middle North America, while the European population suffered harsh climatic conditions during Pleistocene glaciations and retired into Balcanic and Iberian refugia, speciating into the relictic *P. mariae* and *P. baenai*.

The second hypothesis differs only in that the supposed ancestor was present only in Euramerica (Late Cretaceous) and that the Eastern American population invaded Western America after the drying of the Mid-Continental Seaway in the Early Tertiary.

01-166

THE WORLD WEEVIL DATABASE PROJECT
(COLEOPTERA: CURCULIONOIDEA)

J. Rheinheimer

Merziger Str. 24, D 67063 Ludwigshafen, Germany

Information concerning biology, ecology and systematics of larger insect groups is tremendous and widely scattered in the literature. Comprehensive up to date monographs on a worldwide scale are therefore rare or non-existing for many taxa. This makes it difficult even for the specialist to obtain relevant information needed for identification, biological, ecological or biocontrol work.

For this reason an efficient bilingual database system has been developed to handle pictures and text. The software can be used for any taxon. Additions made by different researchers can be combined for regular updates. Various types of lists can be printed or exported.

So far more than 27000 species and genera and 7000 synonyms of Curculionoidea have been included covering the fauna of the Americas, Australia and parts of Europe and Asia. Contained are distribution, host plants (where available), pest status, biological control potential and systematic status. These data are connected to a literature database with 5500 publications listed. Currently 700 full colour pictures illustrate typical representatives of common genera, biotopes and details for identification.

The phylogenetic arrangement of taxa on a worldwide scale has been tried in spite of sometimes contradictory evidence from literature. As much work will still be needed here, the database system has been devised to allow quick modifications.

Future perspectives include the completion of the data for the group studied on a worldwide scale. Another important goal is the assembly of determination keys to be used with the database.

01-165

EXTERNAL MALE SEXUAL CHARACTERS IN THE APIONIDAE (COLEOPTERA, CURCULIONOIDEA) AND THEIR PROBLEMATIC USE FOR PHYLOGENETIC ANALYSES

M. Wanat

Museum of Natural History, Wroclaw University, Poland

Apart from the differences in rostrum shape, almost universal among Apionidae and being an evident female adaptation to the kind of plant, place and way of oviposition, male structures facilitating a firm grip on the female during copulation are main characters responsible for sexual dimorphism in this family. At least 19 major types of modifications can be recognised, which apparently approximates the number of "technically" possible solutions. The most common are modified tibial apices or (never simultaneously) undersides of basal tarsal segments, but such characters can be found also on coxae, femora, metasternum, abdominal ventrites, and even on antennae or aedeagus (examples illustrated). These characters are generally much more popular and diverse in apionids than in other weevil families, which may result from their very convex body and closely situated coxae.

Although diagnostically invaluable, such characters should be, however, cautiously used for cladistic analysis. Being not typical epigamic characters, with few exceptions (mucrones in *Trichapion* and *Apiotherium* complexes, specialised femoral areas in *Fallapion*) they do not undergo sexual selection (in Darwinian sense). For several reasons such structures are commonly homoplasious:

- a) a high selection pressure favouring appearance of any character of this kind, as directly influencing successful gene transfer of its possessor;
- b) morphological simplicity; they are easy to appear;
- c) functional limitations cause numerous repetitions of the same idea;
- d) uniform body shape in apionids leads to similar solutions;
- e) further complication or evolutionary change is unnecessary (unless female body shape changes considerably).

01-167

PHYLOGENETIC STUDIES ON INDIAN ZYGOPINAE WITH PARTICULAR REFERENCE TO THE STRUCTURE OF EXTERNAL GENITALIA (CURCULIONIDAE: COLEOPTERA)

D. KUMAR

Department of Zoology, Govt. College for Girls, Sector 42, Chandigarh, India.

The members of subfamily Zygopinae mainly include stem borers and attack many forest and crop plantations. The various characters of taxonomic importance have been taken into account for clear understanding of disputed-related species.

Besides thorough sampling, identification and description of new and old taxa, a particular stress has been laid on the structure of genitalia as means of divergence and phylogenetic relationship within the taxa of the subfamily and its status vis-a-vis other subfamilies. The structure of genitalia in the studied species shows that it conforms to basic pattern characteristic of the family Curculionidae in general. It has been observed that the condition of endophallic armature in male, and shape and size of spermatheca in female show variations of phylogenetic significance. The details of the structure of phylogenetic importance will be presented.

01-168

PHYLOGENY OF GENUS *Sitona* Germar, 1817 (COLEOPTERA, CURCULIONIDAE).

A.J. Velázquez de Castro
Departamento de Biología Animal I (Entomología). Facultad de Biología. Universidad Complutense. Madrid. Spain.

A phylogenetic study of the genus *Sitona* was made to test the present classification of this group, which includes three subgenera, one of them, the nominotypical subgenus comprises also several species-group (Sectio) as established by Reitter in 1903. New characters were studied, from male and female genitalia, including internal sac, mouth parts, proventriculus and metendosternite. A matrix was made including new and previously used characters to construct a cladogram. Results show that:
Subgenus *Charagmus* Sconheir, 1826 is well defined by several apomorphies.
Subgenus *Coelositona* González, 1971, previously considered monospecific, must include more species.
Subgenus *Sitona* Germar, 1817 is polyphyletic, some of the species are to be included in *Coelositona*, others must form a new subgenus and only the rest must remain in this subgenus. Only part of the groups defined by Reitter are supported by synapomorphies.
The new classification of *Sitona* shows consistence with recent data on phylogeny of Leguminosae based on analysis of chloroplast genome.

01-170

BARK BEETLE COEXISTENCE IN LEAFSTALKS: ECOLOGICAL SUCCESS IN A NUTRIENT-POOR HABITAT.

B. Jordal, L. Kirkendall, H. Brueland and B. C. Nygård

Institute of Zoology, University of Bergen, Norway

A guild of bark and ambrosia beetles, longhorn beetles and zygopine weevils inhabits dead leafstalks of neotropical *Cecropia* species. In Costa Rica, of scolytids we found 11 specialist (*Scolytodes*) species and 14 generalists (6 genera); we also recorded 9 zypogine species and 2 cerambycids breeding in *Cecropia* petioles.

Our research has focused primarily upon the most common group, the scolytids. Fecundities of leafstalk scolytids are among the lowest for any animal; nevertheless, host specific species are very successful, and a mixture of host-specific and generalist species coexist in *Cecropia* patches. The taxonomy and biogeography of these beetles are presented, along with ecological and behavioral data. The leafstalk guild is proposed as a model system for studying ecology and evolution in patchy tropical habitats.

01-169

HOST AND REFUGE PLANTS OF COLEOPTERA CURCULIONOIDEA

E. Colonnelli, G. Osella¹
Via Nicolò Piccinino 15, Rome, Italy - 1 Dipartimento di Scienze Ambientali, Università de L'Aquila, L'Aquila, Italy

Knowledge of host plants of Curculionoidea is of paramount importance. Many taxonomists have apparently not given the right emphasis to it in the past. Refuge plants are here intended as those used by a species as feeding resource, mainly of adults, when usual hosts are not available. Efforts to find out host and refuge plants of Curculionoidea are notably important for taxonomy, evolution, applied entomology, and ecology. Most probably oligophagous weevils predators of epigeal parts of herbaceous plants, particularly annuals, are more subject to selection pressure. Multivoltine species should be forced to use additional hosts to survive when unfavourable conditions arise. Shifting from the usual host to another can be supposed relatively easier in them than in root or wood feeders, which have also longer life as a rule. Can shiftings of adults from a plant to another bring to an evolutionary event? Although this is presently not supported by experimental data on short-term period, it is possibly of considerable weight in a long-term one. It seems very important that scientists note relationships of any kind between weevils and plants, both in the larval and adult stage. This would lead to evidenciate sibling species, to discover different ways of life of adults and larvae, and to differentiate monophagous or oligophagous species from related presumable polyphagous ones. Since many weevils play a remarkable role as pests of cultivated plants or as biocontrol agents, investigation about their host and refuge plants may be a linking point between taxonomists and applied entomologists.

01-171

WHAT MAKES "COMMON" SCOLYTIDS COMMON?

L. R. Kirkendall and K. H. Thunes
Institute of Zoology, University of Bergen, Norway

"Commonness" is discussed, for neotropical bark and ambrosia beetles. Successful tropical scolytids tend to be (a) both widespread and abundant, locally and regionally; (b) inbred, through regular brother-sister mating; (c) fungus-farming or breeding in twigs and seeds; and (d) host generalists. Common species are also sometimes "pests" in agriculture or forestry. Patterns in commonness are compared, for Costa Rican scolytids in primary, secondary, and planted forests, for certain "life styles", and for continuous vs. patchy habitats, and implications for conservation and forestry discussed. The presumed high levels of homozygosity in widespread and abundant tropical scolytids seems paradoxical in light of ("Red Queen") theories emphasizing the importance of genetic variability for competing in biotically complex environments.

01-172

PHYLOGENY AND EVOLUTION OF PARTHENOGENESIS IN THE GENUS *ARAMIGUS* HORN (COLEOPTERA: CURCULIONIDAE): A STUDY INTEGRATING MOLECULAR AND MORPHOLOGICAL DATA

B. B. Normark¹, A. A. Lanteri²

¹. Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, USA. ². Departamento Científico de Entomología, Museo de La Plata, La Plata, Argentina.

Aramigus Horn, which includes a number of parthenogenetic lineages, has been the subject of 2 recent phylogenetic studies, one using morphological characters and one using mitochondrial DNA (mtDNA). In the present study we integrate these two approaches.

We analyzed 39 terminal units (TU's) of *Aramigus* from which mtDNA and/or morphological data were available, and selected 32 morphological characters (21 informative) and 792 base pairs of mtDNA. Analysis of the morphological data left many relationships unresolved, especially within the *A. tessellatus* species complex. Analysis of the molecular data provided a better resolution. The strict consensus of all mtDNA and morphological MP trees was virtually unresolved.

We also conducted parsimony analyses for the 34 TU's from which both mtDNA and morphological data were available (M + M TU's) and we obtained 2 MP trees. One of these trees was completely congruent with one of the 14 MP mtDNA trees. Both MP trees showed a single topology for the *A. tessellatus* complex and implied 3-4 origins of parthenogenesis within the complex. When all 39 TU's were considered, there were 5 MP trees, differing only in the placement of the *biseriatus* morphotype of *A. tessellatus*. These 5 trees were all congruent with one of the 2MP trees for 34 TU's and implied 3-5 origins of parthenogenesis within the *A. tessellatus* complex. We interpret the single tree that was found by both the mtDNA and combined analyses as the best-corroborated estimate of maternal-lineage genealogy for *Aramigus*.

01-173

TRICHOGRAMMA TAXONOMY WORKSHOP: TOWARD A STABLE NOMENCLATURE FOR THE SPECIES OF TRICHOGRAMMA (HYMENOPTERA: TRICHOGRAMMATIDAE)

B. Pintureau, J. D. Pinto¹

I.N.S.A., UA INRA 227, Biologie 406, 20 avenue A. Einstein, F-69621 Villeurbanne, France -¹ Department of Entomology, University of California, Riverside, CA USA

Species of the genus *Trichogramma* are among the most widely used biological control agents in the world. Unfortunately, optimum utilization of these insect egg parasites has often been compromised by disagreement over the identity of some of the most common and important species. For example, there has been no unanimity among taxonomists as to the definition of such frequently studied species as *Trichogramma evanescens* Westwood, *T. euproctidis* (Girault), *T. cacoeciae* Marchal, and *T. brasiliense* (Ashmead). Most of the controversy is due to the absence or inadequacy of type material. The purpose of this workshop is to clearly identify the most important sources of disagreement and to recommend solutions that will insure nomenclatural stability. Workshop participants will include several specialists currently active in the taxonomy of the genus.

01-174

HOFFER-FLIES (DIPTERA: SYRPHIDAE) OF UZBEKISTAN
D. B. Daminova

Institut of Zoology and Parasitology, Tashkent,
Uzbekistan

One hundred feventy eight species of Syrphidae from 34 genera are known in Uzbekistan. The greatest amount of species occurs in mountain zone (115 species, or 89.8%). Fifty five species (42.9%) are known from the foot-hills zone. Twelve species (9.3%) are known in desert zone and 33 species (25.0%) - in the tugai zone of rivers. Fifty one species (39.8%) occurs environment which is under anthropogenic pressure. Forty seven species (39.0%) have aphidophagous larvae. Abundance, period of activity, number of generation, puculiarities of feeding, hibernation, and natural enemies of aphidophagous Syrphidae are discussed. Some new methods of artifical culturing of aphidophagous species are also discussed.

01-176

SYSTEMATIC REVIEW OF THE AFRICAN GENERA
PSAMMOTHERMA, *ANTENNOTILLA* AND *CTENOCERAEA*
(MUTILLIDAE, HYMENOPTERA), WITH REMARKS ON THE
SUBTRIBE SMICROMYRMINA

A. Četković, G. Nonveiller¹

Institute of Zoology, Department of Biology, University of Belgrade, Belgrade,
Yugoslavia; 1 -- Nušićeva 2a, Zemun, Yugoslavia

Three genera of African mutillids, *Psammotherma* Latreille, 1805, *Antennotilla* Bischoff, 1920 and *Ctenoceraea* Nonveiller, 1993, are unique within the whole family for having a peculiarly modified antennal flagellomeres (all taxa known from male sex only).

In the course of the extensive revisionary studies on the Afro-tropical fauna, and particularly in connection with the discovery of *Ctenoceraea*, the examination of the type material resulted in revision of both older taxa, with significant redefinition of the concept of original *Antennotilla*. This primarily monotypical genus (*A. phoebe* Péringuey) should be broadened to include *Psammotherma cyanochroa* André, but also several other species (most of them apparently new) showing various degrees of antennal modifications, as different states of the same morphological trend (with *A. cyanochroa* having the most advanced and rather unusual one). The definite limit of this genus is still difficult to determine, since it involves the revision of a number of species, currently recognizable only as members of the large "genus" *Smicromyrme* sensu lato. The revised genus *Psammotherma* is morphologically rather homogeneous, comprising only 4 species, and *Ctenoceraea* is currently monotypical. Their antennal modifications are of two distinct forms, but both can be described as pectinate (the rare antennal type within Hymenoptera); no morphologically intermediate states have been recorded within the Mutillidae.

All the examined taxa belong to the *Smicromyrme*-group of genera (in Africa comprising also *Corytilla* Arnold, *Pseudocephalotilla* Bischoff, *Sulcotilla* Bischoff and only tentatively *Guineomutilla* Suarez, as well as some other female-based undescribed genera), which probably constitutes the most primitive section of the large and diverse subtribe Smicromyrmina (sensu Brothers, 1975). However, each of them represents an independent phylogenetic lineage within the group: *Ctenoceraea* being the most closely related to *Corytilla*, and two others to different subgroups of heterogeneous African "genus" *Smicromyrme* s.l. The true *Smicromyrme* Thomson is probably absent from the tropical Africa.

01-175

PHYLOGENETIC RELATIONSHIPS AMONG THE GENERA OF THE
SUBTRIBE GYMNOLEURINA (COLEOPTERA SCARABAEIDAE
SCARABAEINAE): PRELIMINARY RESULTS.

M. Luzzatto, E. Barbero, C. Palestini

Dipartimento di Biologia Animale, Università di Torino, Torino,
Italy.

The last important study of the subtribe Gymnoleurina was carried out by André Janssens (1940). The Belgian entomologist, considering external morphological characters only, enlisted 91 species and grouped them into four main genera: *Paragymnoleurus* Shipp, *Garreia* Janssens, *Allogymnoleurus* Janssens, and *Gymnoleurus* Illiger. A few new species have been described in recent years.

According to Janssens, Gymnoleurina have to be considered a homogeneous taxon. Species are distributed in Africa and Asia, reaching the islands of the Malaysian archipelago, Sumatra, Java, Borneo, and Philippines. Only a few species are known from southern Europe.

At this stage of our research - within the framework of the phylogenetic revision of the whole subfamily Scarabaeinae - we took into account 22 species belonging to the four generally accepted genera.

We considered 33 characters obtained from external morphology, epipharynx, male and female genitalia. On the basis of these characters we carried out a phylogenetic analysis, using different computer packages (PAUP, MacClade, and PHYLIP).

Characters were considered unordered, and trees unrooted, since a sufficiently reliable outgroup seems not to be available without a precise phylogenetic hypothesis concerning the whole subfamily.

Data hitherto processed produced several trees which show a quite good differentiation into natural groups, thus essentially confirming, with some poor rearrangements, the monophyly of the genera stated in current literature.

01-177

SYSTEMATICS, CLADISTICS AND BIOGEOGRAPHY OF *ENTOMODERES*
SOLIER, 1836 (COLEOPTERA: TENEBRIONIDAE: NYCTELIINI)

G. E. Flores and S. Roig-Juñent

IADIZA, Instituto Argentino de Investigaciones de las
Zonas Áridas, C.C. 507, 5500 Mendoza, Argentina

Entomoderes comprises nine species that occur in South America, southern parallel 17 and are insects endemics to dry areas in central and northern Argentina and southern Bolivia, principally in Monte and Chaco formations. This genus is a monophyletic group, defined traditionally by the lateral expansions of pronotum. The genus is revised, providing redescrptions and illustrations of its species based on the external morphology and male and female genitalia, a key for identifying them, and distributional maps. Analysis of material from northern Argentina revealed a new species that is described. The cladistics analysis was based on 30 characters, and the polarity of them was determined using the genus *Pilobalia* Burmeister. Characters with more than one apomorphic state or not comparable with the outgroup were treated as nonadditive. Using the program Pee-Wee only one cladogram with best fit was obtained. The analysis shows that eleven new characters constitute synapomorphies of *Entomoderes*. The cladogram obtained shows two basal groups, first the sister species *E. erebi* and *E. cellulosus*, and a second monophyletic group constituted by the remain species, both groups supported by structures of pronotum and elytra. Only three characters show parallel or reversal evolution. Information on geographical distribution was used along the tree to analyze vicariant events. Three main areas of endemism could be determined for *Entomoderes* species: Chaco (2 species), southern Monte (2 species), and northern Monte (4 species). One species (*E. draco*) is widespread. The only vicariant event, that is shows by others taxa of Coleoptera (*Cnemalobus*, Carabidae; *Enoplopactus*, Curculionidae) is the separation of northern Monte with Chaco-southern Monte. These areas are separated by mountain chains in Salta, Tucumán, Catamarca and La Rioja provinces (Argentina).

01-178

EVOLUTIONAL PATTERN OF PSYLLID MALE REPRODUCTIVE SYSTEM(HOMOPTERA:PSYLLOIDES)

H. C. Park, I. D. Hodkinson¹, D. Hollis³

Department of Biology, Kyungpook National University, Taegu, Korea

¹School of Biological & Earth Sciences, Liverpool John Moore University, Liverpool, England²Department of Entomology, British Museum Natural History, London, England

The follicle number of male testes of psyllid was two in mode, which has 76% in the frequency, distributes worldwide, occur from the all families of this group. The numeric variation of follicle was one to twelve, and one follicle type comes from the Gondwanan region and the family Spondyliaspidae and Aphalaridae. Four follicle type is popular in the Palearctic and Oriental continent, and the genera Psylla, Eritriozia, and Cyamophila etc.

01-180

A SYSTEMATIC STUDY OF THE MESOCHORINAE(HYMENOPTERA : ICHNEUMONIDAE) FROM THE EASTERN PALEARCTIC REGION

Jong-Wook, Lee, Kyong-In, Suh & Jin-Yeoul, Cha

Department of Biology, Yeungnam University, Kyong-san 712-749, Korea

Taxonomic, morphometric, phenetic and cladistic analyses were performed using the subfamily Mesochorinae which collected from Eastern palearctic region and the following results were obtained.

As a result of taxonomic study, a total of 5 genera, 70 species was confirmed in the Eastern palearctic Mesochorinae. Among them, four species of *Astiphromma* and four species of *Mesochorus* are new ones. In addition, six species (*A. confusum*, *A. varipes*, *M. confusus*, *M. fuscicornis*, *M. rubranotatus*, *M. uniformis*) are new to Eastern palearctic regional fauna.

In order to clarify the interspecific variation of *Astiphromma jezoense*, a morphometric analysis was performed for seven populations using PCA (principle component analysis) and discriminant analysis. As a result of PCA, 25 quantitative characters are grouped into four factors. The characteristics on legs are especially important components both in male and in female. Morphometric analysis indicate that considerable morphological gap is correlated with geographical habitat.

In the phenetic analysis, clustering patterns which obtained from different methods using different numbers and characters represent the degree of interspecific morphological similarity. The results provide information to preparing useful key for the Eastern palearctic Mesochorinae.

A single parsimonious cladogram was obtained from cladistic analysis. The genus *Cidaphus* was the basal clade among five genera. Four other genera were branched in the order of *Astiphromma*, *Mesochorus*, *Stictopisthus* and *Plectochorus*. Among them, two genera *Stictopisthus* and *Plectochorus* form a sister group.

01-179

TAXONOMY AND PHYLOGENY OF THE SUBFAMILY TRYPHONINAE (HYMENOPTERA : ICHNEUMONIDAE)

Jong-Wook, Lee, Jin-Yeoul, Cha & Kyong-In, Suh

Department of Biology, Yeungnam University, Kyong-san, 712-749, Korea

For the taxonomic and phylogenetic studies of the subfamily Tryphoninae (Hymenoptera : Ichneumonidae), specimens were collected from March of 1988 to September of 1995 in the southern part of Korean peninsula. Specimens were also obtained from various museums and laboratories both in Korea and in other countries. This research utilized about 1,000 domestic specimens and 3,010 foreign specimens including 10 specimens from North Korea.

Four tribes, 23 genera and 72 species a total is distributed in Korean peninsula including previously unrecorded eight genera and 24 species.

In order to get a desirable results from morphometric analysis, both PCA and discriminant analyses were performed. Morphometric analysis indicate that length of lateral carina of scutellum, width of face, width of clypeus, length of 2rm + 3rm and Length of Cul between Cua and 1mCu(fore wing) are important factors to classifying the subgenera. It could overcome the problems following subgeneric classification if these characters were incorporated into subgeneric classification system.

The cluster and discriminant analyses suggest that the Townes(1969) and Townes et al.(1992)'s systems are well fit for the classification of Tryphoninae. Cladistic analysis indicate that the Tryphoninae is a polyphyletic group and do not fit to the basic concept of natural classification because of its complex classification system. Tribes Sphintini and Ankylophonini, due to its host specificity, can be seen the results of convergent evolution.

According to zoogeographic studies, large numbers of species originating from the palearctic region and a large percentage of endemic species, I can assume that the Korean Tryphoninae crossed over from northern hemisphere.

The fossils were found at the Cretaceous amber located at the Siberia peninsula, Taimyr. I think it to be the dispersion center. The world-wide distribution of the Tryphoninae seems to coincide with the continental movement.

01-181

PHYLOGENY AND EVOLUTION OF THE STAPHYLINID TRIBE SCAPHISOMATINI (COLEOPTERA)

I. Löbl, Muséum d'histoire naturelle, 1211 Geneva 6

R. Leschen, Michigan State University, East Lansing, MI 48824, USA

Leschen and Löbl (1995) examined the phylogenetic relationships of the fungus feeding staphylinid subfamily Scaphidiinae (consisting of the tribes Cypariini, Scaphiini, Scaphidiini and Scaphisomatini). In their study, however, Scaphisomatini was treated superficially and was represented in the data matrix by two terminal taxa. We conducted a preliminary cladistic study of Scaphisomatini (which includes about 35 described genera) by including two genera from each of the subtribes (Heteroscapina, Baeoceridiina, Baeocerina, Scaphisomatina, and Toxidiina). This analysis, based on 11 terminal taxa (including a generalized outgroup) and 34 characters, resulted in three parsimonious reconstructions of relationships. Each of these show that all subtribes are polyphyletic with the exception of Baeoceridiina which in two trees are monophyletic and sister taxon of Scaphisoma (Scaphisomatina). These data suggest the current classification is unsatisfactory and must be changed to reflect natural groupings. Our results are interesting because most members of Baeoceridiina are associated with Old World termites suggesting that the evolution of social insect inquilineism may have evolved one time in the subfamily.

01-182

A TAXONOMIC STUDY OF THE JAPANESE SPECIES OF THE GENUS *FARISTENIA* (LEPIDOPTERA, GELECHIIDAE).

Tatsuya Ueda

Entomological Laboratory, College of Agriculture, Osaka Prefecture University, Sakai, Osaka 593, Japan

The genus *Faristenia* was proposed by Ponomarenko in 1991 for the Russian species and she described seven new species. Park (1993) revised the genus with descriptions of three new species and redescription of five known species from Korea. Ponomarenko (1991) stated that the genus *Faristenia* is related to the genera *Hypatima* and *Dactylethrella* and Park (1993) placed the genus between them. In Japan five species belonging to the genus are recorded fragmentarily by Park (1993) and Ueda (1995), however, revisional study of the genus has never been done. After examination of Japanese *Faristenia*, I reached the following conclusions:

- 1). Ten species of the genus occur in Japan and some of them must be described as the new to science.
- 2). The monophyly of the genus is supported by the following synapomorphies: the presence of hair pencils at the basal portion of the cell on the hindwing in the male; the tegumen with inflated basal half in the male genitalia; the coiled ductus ejaculatorius in the male genitalia; the coiled ductus bursae in the female genitalia.
- 3). The short gnathos of the genera *Faristenia*, *Dendrophilia* and *Capidentalia* are considered to be apomorphic condition shared by these genera in the subfamily Chelariinae.

01-184

SYSTEMATIC AND DISTRIBUTIONAL STUDIES OF ASIAN *ANDRENA* (HYMENOPTERA, ANDRENIDAE)

O. TADAUCHI, H.-I. XU

Entomological Laboratory, Faculty of Agriculture, Kyushu University, Fukuoka, Japan

After Smith (1869) described *Andrena halictoides* from Japan, many species of the genus *Andrena* have been discovered and described. We have started to make a survey of this group in China mainland since 1993 and also have started to study materials collected from Japan, China, Korea, Formosa and Maritime Districts of Russia. We have described new species and have determined systematic positions of described species. In the present study we show outline of systematic and distributional studies of Asian *Andrena* with special references to principal subgenera, such as *Andrena* s. str., *Hoplendrena*, *Holendrena*, *Simandrena*, *Micrandrena*, etc.

01-183

THE EVOLUTION OF EGG CHARACTERS IN SOME TRUE BUGS (HEMIPTERA: HETEROPTERA: PENTATOMOIDEA)

M. Javahery

Lyman Entomological Museum & Research Laboratory, Campus Macdonald of McGill University, Ste. Anne De Bellevue, Quebec H9X 3V9 Canada

The evolution of egg characters in Pentatomoidea are traced from the fundamental characters that have true phylogenetic value. These characters have been separated from those that are temporary adaptations to specific environments.

The phylogeny of 23 genera of Pentatomoidea, based on embryogenesis, embryonic orientation, characteristics of the chorion, the number and size of the micropyle, location and thickness of the "T"-or-"Y"-shaped egg-burster, mechanisms of hatching, colour, and egg form shows, the genera *Elasmucha* and *Sehirus* as the probable outgroups.

Based on the above characters, the superfamily is divided into two groups: (1) Acanthosomatidae, Cydnidae, and Thyreocoridae; and (2) Pentatomidae and Scutelleridae. The first group, particularly Acanthosomatidae and Cydnidae, are ancient and primitive families.

The three forms of narrowed rounded ends, spherical, and cylindrical shell in the superfamily have evolved independently, and along different pathways from an ovoid ancestral egg.

01-185

AN ELECTROPHORETIC CHARACTERIZATION OF THE ITALIAN SPECIES OF *SIGARA* S. STR. (HETEROPTERA: CORIXIDAE)

Di Giovanni M.V., Rizzotti Vlach M.¹, Giangiuliani G., Goretti E., Veronesi F.²

Istituto di Zoologia, Facoltà di Scienze MM. FF. NN., via Elce di Sotto, 06123 Perugia, Italy - ¹ via Villa Cozza, 16, 37131 Verona, Italy - ² Istituto di Miglioramento Genetico Vegetale, Facoltà di Agraria, Borgo XX Giugno, 72, 06121 Perugia, Italy.

Some years ago, individuals belonging to the genus *Sigara* (subg. *Sigara* s. str.) (Heteroptera: Corixidae) were founded in Central Italy (Di Giovanni et al., 1984). These individuals seem to represent another species as regard to the similar species *S. dorsalis* (Leach) and *S. striata* (Linnaeus). The taxon, still named *Sigara* sp. is different from the other especially for the parameres morphology, size of the strigil and shape of the eight urotergite.

The objective of the present study is to investigate the biochemical differences and to describe the genetic structure of the different Italian populations of *S. striata* (La Muta Lake - Trentino A. Adige) *S. dorsalis*, (Belfiore - Veneto) *Sigara* sp. (Tresa stream - Umbria; Zittola swamp - Molise) using electrophoretic techniques. Alleles were distinguished by means of horizontal starch electrophoresis of homogenized specimens. Genetic differences were measured using Nei's genetic distance (D) (Nei, 1978) and illustrated in a dendrogram constructed by the unweighted pair-group method using arithmetical averages (UPGMA) (Sneath & Sokal, 1973). The biochemical differences strengthen morphological observations confirming the presence of three different allopatric species of *Sigara* in Italy.

01-186

IDENTIFICATION OF SOME *EMPOASCA* SPECIES BY MEANS OF ELECTROPHORESIS AND SCANNING ELECTRON MICROSCOPY

S. Demichelis, A. Manino, A. Patetta

DI.VA.P.R.A. - Entomologia e Zoologia applicate all'Ambiente "Carlo Vidano", Università di Torino, Grugliasco, Italy

The genus *Empoasca* Walsh is an economically important group of phytophagous leafhoppers. In Piedmont three species, *E. decipiens* Paoli, *E. solani* (Curtis) and *E. vitis* (Goethe), have been recognised and their life history and pest status are well known.

Empoasca males are classified by means of the analysis of genitalia, while females cannot be identified with certainty from their morphological characteristics. As it is desirable to identify the species also using the female sex, other features by means of electrophoresis and scanning electron microscopy have been searched.

Tetrazolium oxidase or superoxide dismutase (TO or SOD) and glucose-6 phosphate dehydrogenase (G-6PDH) enzyme systems proved to be a reliable tool for classifying the three *Empoasca* species.

Also the analysis of the ovipositor showed some useful characteristics for the specific identification. The valvulae dissected from the females used for electrophoresis have been observed and each species specific character has been associated with electrophoretic data.

01-187

MORPHOLOGICAL ELEMENTS FOR A KEY TO SUBGENERA OF THE GENUS *BOMBUS* LATREILLE S.L. REPRESENTED IN ITALY (HYMENOPTERA APOIDEA).G. Bolchi, F. Intoppa¹, M. G. Piazza.¹

Istituto di Entomologia agraria, Università degli Studi, Milano, Italy - ¹ Istituto Sperimentale per la Zoologia agraria, Sezione Apicoltura, Roma, Italy

According to a list drawn up on the basis of the literature, examination of museum material and specimens captured for study purposes, there are 33 Italian species of the *Bombus* Latreille s.l. divided amongst 13 subgenera.

Of these subgenera the morphological characteristics of queen and worker heads are described, with definition of the variability and diagnostic value. The elements studied concern: the ratio of length and breadth of the head itself; the direction of the longitudinal axis of the eyes; forehead puncture; dorsal furrow of the temples; dimension, shape and puncture of the clypeus; proportions of the malar space; the position of the ocelli; dimensions of the antennal segments; the structure of the superior labrum; the structure of the mandible.

The characteristics listed, derived from the descriptions and dichotomic keys of various Authors, have been objectively compared with examples of each species, thereby permitting confirmation or correction.

Here these characteristics are set out in synoptic tables and illustrated with SEM photographs.

01-188

IDERATUS THOMSON, 1864 (COLEOPTERA, CERAMBYCIDAE, CERAMBYCINAE): REDESCRIPTION AND TAXONOMIC POSITION.

D.S. Napp

Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brasil.

Ideratus Thomson, 1864 was proposed for a single species, *I. cyanipennis* Thomson, 1864, from Colombia, and placed near *Callichromopsis* Chevrolat, within the Subtribe Callichromitae, Division Callichromitae Verae, far from the Compsocerini Thomson, 1864 (THOMSON, 1864). LACORDAIRE (1869) included *Callichromopsis* in Compsocerini but did not mention *Ideratus*. After the original description, the only mention to the genus was that of AURIVILLIUS (1912) who included it in Compsocerini. Therefore, *Ideratus* remained almost unknown up to now. The only known representative of *I. cyanipennis* is the type-specimen, a female.

The genus and the species are redescribed and illustrated based on the study of the holotype. The taxonomic position of *Ideratus* in relation to predominantly Neotropical tribes with finely faceted eyes is discussed. It was found that the genus is not a Compsocerini, and also shows no affinities with genera of other Neotropical tribes. So it is removed from Compsocerini and until further studies are possible, considered as in Incertae sedis.

01-189

A NEW SPECIES OF *AZYA* MULSANT FROM BRAZIL (COLEOPTERA, COCCINELLIDAE, COCCIDULINAE) FEEDING *PULVINARIA PARANAENSIS* HEMPEL, 1929 (HOMOPTERA, COCCIDAE) ON *ILEX PARAGUARIENSIS* ST.HIL. (AQUIFOLIACEAE)L.M.Almeida, R.C.Z.de Carvalho¹

Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brazil - ¹ Secretaria de Estado da Agricultura e do Abastecimento do Paraná, Centro de Diagnóstico Marcos Enrietti, Curitiba, Paraná, Brazil.

The genus *Azya* Mulsant has thirteen Neotropical species. Most of them have potential importance for biological control and have been introduced in other regions of the world. A new species from Bituruna and Cruz Machado, Parana State, was found feeding voraciously on *Pulvinaria paranensis* Hempel, 1929 from *Ilex paraguariensis* St.Hil. an important crop of southern Brazil. A detailed morphological study of the male and female genitalia is presented and illustrated. This new taxon is included into the existing key to species.

01-190

PHENETIC ANALYSIS OF BRAZILIAN SPECIES OF *AMBLYCERUS* THUNBERG, 1815 (COLEOPTERA:BRUCHIDAE).

C.S.Ribeiro-Costa¹

¹Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Brasil.

A detailed morphological study of Brazilian species of *Amblycerus* Thunberg, 1815 resulted in the definition of 83 characters, mainly external, from which 34 were quantitative and 49 qualitative. The phenetic relationship among the 56 OTU's was performed using both the Cluster and Principal Component Analyses. The results obtained by these two complementary technics showed two large groups, suggesting the existence of two taxa at the generic level; one of them was considered new. The Cluster Analysis, regarded as the most appropriate technique to reproduce distances between close neighbors, made possible the definition of 22 species groups with 1 to 8 species each.

01-192

STUDIES IN THE SYSTEMATICS AND BIOLOGY OF THE EASTERN PALAEARCTIC MORDELLID BEETLES (COLEOPTERA: MORDELLIDAE)

Vladimir K. Odnosum

I.I. Schmalhausen Institute of Zoology, National Academy of Sciences of Ukraine, UA252601 Kiev, Ukraine

By far, the mordellid beetles were poorly examined in the Eastern Palearctic. In 1975-1995, over 7,000 specimens were collected by sweeping and reared by the author. Numerous materials from the most important collections, including primary type specimens, were examined. This work was resulted in the revised list of taxa occurring in this area. The further studies of reared materials allow to identify several species of the genera *Tomoxia*, *Hoshihananomia*, *Variimorda*, *Mordella*, *Mordellistena* et al. from larvae.

There are significant affinities in larval morphology and habitats between several species forming groups those include both closely related and non-related species with similar biology; they are recognised as the morphofunctional groups, showing numerous cases of homoplastic characters. They appear independently due to general direction of morphofunctional specialisation in different lineages of Mordellidae. Further, the comparative morphological study of wing structures gives a unique possibility to understand the variability of the wing venation and to hypothesise the ways of their specialisation. Life habits of the Mordellidae are broadly reviewed in the presentation.

01-191

A PHYLLOGENETIC ANALYSIS OF THE *EVOPLOTUS* GROUP (HETEROPTERA, PENTATOMIDAE, PENTATOMINI)

J. Grazia

Departamento de Zoologia, Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brasil.

The *Evoplutus* group includes three neotropical genera: *Evoplutus* Amyot & Serville, *Pseudevoplutus* Ruckes and a new genus described by Grazia & Becker (in press). The monotypic genus *Evoplutus* was revised by Grazia et al. 1993; a comparison of morphological characters, including the genitalia, between this genus and *Pseudevoplutus sensu* Ruckes was presented. Grazia et al. 1994 based on detailed studies of the genitalia of both sexes proposed the breakdown of *Pseudevoplutus*. Besides the type species *P. paradoxus* Ruckes, 1958, three new species were added: *P. costalimai* Grazia et al., 1994, *P. peruvianus* Grazia et al., 1994 and *P. vittatus* Grazia et al., 1994. The remaining three species described in *Pseudevoplutus* (*P. longicornis* Ruckes, 1959, *P. casei* Thomas, 1980, and *P. mexicanus* Brailovsky & Barrera, 1982) were transferred to a new genus in which were also described two new species, one from Costa Rica and another from Venezuela (Grazia & Becker, in press). In this paper a table showing the morphological relationships between *Pseudevoplutus* and the new genus was included. Within the family Pentatomidae, just a few papers treated the relationships among genera on modern phylogenetic basis. In the article, the analysis was based in 45 characters, which polarization was obtained by comparison with the outgroup (*Mormidea* Dallas and *Arvelius* Spinola). The cladogram obtained, using HENNIG86 supported the monophyly of the group.

01-193

ON THE IMPORTANCE OF SENSILLA IN THE INTERPRETATION OF WING VEIN REDUCTION IN APHIDIINES (HYMENOPTERA BRACONIDAE)

D.Mancini, E.Tremblay

Dipartimento di Entomologia e Zoologia Agraria, Università di Napoli "Federico II", Portici (NA), Italy

Aphidiines show a variety of wing venations which, starting from a braconoid type (*Ephedrus* Haliday), reach strong simplification (e.g. *Diaeretiella* Stary', *Trioxys* Haliday). Morphological, embryological and ethological data support the idea that, in this group, wing vein reduction increases with the degree of adaptation to parasitoidism. The process of fading and obliteration of venation leads to disappearance of closed cells in the distal part of the wing. In some species of the genus *Aphidius* Nees, the pigmentation of the distal tracts of some veins involved in the process of fainting is variable and causes problems in species discrimination and genus characterization. In these cases, the presence-absence of presumable placoid sensilla, which characterize definite tracts of veins can help in evaluating the degree of their reduction. The closely related parasitoids *Aphidius salicis* Haliday and *Aphidius aquilus* Mackauer can show convergences in degree of fainting of the intermedian+median and interrational veins. Nevertheless, the presence of at least one sensillum at the point where these two veins meet is distinctive of *Aphidius salicis* Haliday in which evidently this point still preserves its function. In *Aphidius aquilus* Mackauer instead, these sensilla and, presumably, the corresponding nerval termination leading to them have irreversibly disappeared. In fact *A. aquilus* is usually reported as having *Diaeretiella*-like reduction of veins. A comparative examination of several other genera of Aphidiines (*Praon* Haliday, *Lysiphlebus* Foerster, *Lipolexis* Foerster, *Monoctonia* Stary') showing different degrees of wing vein reduction has been carried out. This study confirmed the close association of wing veins with these presumed sensorial structures.

01-194

AN IDENTIFICATION EXPERT SYSTEM FOR TORTRICINAE (LEPIDOPTERA) IN CHINA BY COMPUTER IMAGE ANALYSIS OF VENATION

Jing-dong Liu You-qiao Liu¹

Entomological Laboratory, University of Osaka prefecture, Sakai, Osaka, 593, Japan.
¹Institute of Zoology, Academia Sinica, 19 Zhongguancun Road, Haidian, Beijing 100080, China.

The authors have stored into a computer the male and female venations of more than 250 species of tortricids in China. Anyone who wants to identify a chinese tortricid, just needs to draw a figure of its venation, input it into the computer and go through the three steps developed by the authors: 1. Localization of vien point by two-center method; 2. Model modification method; 3. Dissimilarity sequence analysis. Then, he will obtain a correct species name with an accuracy over 95%.

Besides, the authors have also stored into computer the morphological discriptions, life-history, distributions and figures of adult, male and female genitalia of these 250 species, so they can be easily called out for further checking and ensure the success up to 100%.

01-195

PHYLOGENETIC ANALYSES OF THE FAMILIES OF SHORT-TONGUED BEES (HYMENOPTERA: APIFORMES)

B. A. Alexander and C. D. Michener, Snow Entomological Museum, University of Kansas, Lawrence, Kansas, U.S.A.

Phylogenetic analyses of short-tongued bees were made using adult morphological characters of species representing 48 genera of short-tongued bees, 9 genera of long-tongued bees, and 8 genera of wasps in the superfamily Apoidea. Two series of analyses compared the phylogenetic implications of competing hypotheses of character evolution for the glossa. In each series, the effects of various character weighting schemes were compared.

The monophyly of bees is strongly supported. Short-tongued bee families found to be monophyletic in this study are Andrenidae (including Oxaeinae), Halictidae, Stenotritidae (represented in this study by only one species), and probably Colletidae. Melittidae are clearly paraphyletic, and include the short-tongued bees most closely related to long-tongued bees. The Melittidae are subdivided into three families, the Meganomiidae, Dasypodidae, and Melittidae proper. Several conflicting hypotheses of relationships among the families of short-tongued bees are supported in the various analyses, and are highly sensitive to character weighting and assumptions about polarity or ordering of transformation series for a handful of glossal characters.

01-196

PHYLOGENETIC ANALYSIS OF THE FAMILY GROUPS WITHIN THE INFRAORDER PENTATOMOMORPHA (HETEROPTERA)

T. J. Henry

Systematic Entomology Laboratory, Plant Sciences Institute, ARS, USDA, c/o National Museum of Natural History, Washington, D. C., USA

Fifty-seven characters are used to analyze cladistically 34 family group taxa in the Pentatomomorpha. The six superfamilies Aradoidea, Coreoidea, Idiostoloidea, Lygaeoidea, Pentatomoidea, and Pyrrhocoroidea are recognized. New superfamily combinations include the transfer of the Henicocorinae to Idiostoloidea, the Piesmatoidea to Lygaeoidea, and the lygaeid subfamily Psammidae to Piesmatidae. The family Lygaeidae (*sensu lato*) is shown to be paraphyletic and is separated into ten monophyletic family groups. The analysis is performed using both HENNIG86 and PAUP. Character distributions and results using weighted and unweighted data are discussed. A key is offered to facilitate recognition of the superfamilies and a revised classification of the infraorders and their subordinate taxa is proposed.

01-197

PHYLOGENY OF LARVAE AND ADULTS IN W-PALAEARCTIC ONTHOPHAGINI (COL., SCARABAEOIDEA): A TEST OF TAXONOMIC CONGRUENCE.

Fermín Martín-Piera

Dpto. de Biodiversidad y Biología Evolutiva. Museo Nacional de Ciencias Naturales (C.S.I.C.). Madrid, ESPAÑA.

Character congruence is a measure of classifications stability. Since phylogenies are not equally probable, however, not all character sets are adequate bases for inferences on organic evolution.

In order to test the consistency of phylogenies and stability of present classifications of the W-Palaearctic Onthophagini, a test of taxonomic congruence among cladograms showing phylogenetic relationships of adults and larvae was carried out. Twenty five adults characters (external morphology and male/female genitalia), and 23 larval characters were polarized. Adults of 31 species and larvae of 19 species, belonging to all Onthophagini's subgenera of the W-Palaearctic Region, were studied.

Phylogenetic trees were calculated running "Hennig86" and "PAUP" packages. Consensus trees and dissimilarity measures (Partitions, Symmetric Difference -SD-, Strict Joint Assertions -SJA-) among tree profiles were obtained by using the "COMPONENT" package.

Results indicated that SD and SJA measures for triplets among phylogenies inferred from adults and larvae range from 0.355 to 0.544 (mean=0.468), and from 0.269 to 0.477 (mean=0.377), respectively. For quartets, SD and SJA measures range from 0.540 to 0.652 (mean=0.597), and from 0.344 to 0.487 (mean=0.416). Comparisons between Nelson consensus trees of adults and larvae, show quite similar figures for all dissimilarity measures.

Differences in the number of studied taxa (adults of 31 species and larvae of 19 species) show not bias on tree dissimilarity measures.

A brief discussion on the possible causes of this moderate taxonomic incongruence between phylogenies inferred from adults and larvae is presented, however, more questions than answers still remain.

01-198

TAXONOMY AND BIOLOGY OF JAPANESE ADELIDAE (LEPIDOPTERA)

Toshiya Hirowatari

Entomological Laboratory, College of Agriculture,
Osaka Prefecture University, Sakai, Osaka, 593 Japan

The family Adelidae of Japan comprises 3 genera, i.e., *Adela*, *Nemophora*, *Nematopogon*. The family has been fragmentarily studied and the arrangement was made by Moriuti (1982) checking up 25 species from Japan. However, no revisional work has been made since Matsumura (1932) listed Japanese species. Recently Hirowatari (1995) added two new *Nemophora* species to the fauna.

As a result of tentative arrangement, at least 31 species were recognized in Japanese Adelidae, including 5 new species and 1 unrecorded one.

Though the adelid species is relatively abundant in Japan, life history of the almost species has been unknown except only two species, *Nemophora raddei* (Rebel) and *N. albi antennella* Issiki. In order to provoke attention, possible host plants of some species are provided mainly based on the author's observation.

In addition, daily activity patterns of some adelid moths are discussed in the light of evolution of their precopulatory behavior.

01-200

STAPHYLINIFORMIA (COLEOPTERA): A MONOPHYLETIC GROUP?
M. Hansen, Entomological Department, Zoological Museum,
Copenhagen, Denmark

A close relationship between the superfamilies Hydrophiloidea, Histeroidea (sometimes included in the former) and Staphylinoidea has long been recognized. The three groups are collectively referred to as Staphyliniformia. The phylogenetic status of this large series of polyphagan Coleoptera has been reanalysed on the basis of the distribution of approximately 120 adult and larval characters in 30 staphyliniform subgroups and 7 representatives of more-or-less closely related groups of beetles.

The analysis confirms the current concepts of Hydrophiloidea, Histeroidea and Staphylinoidea and strongly supports the hypothesis that the family Hydraenidae belongs to Staphylinoidea rather than to Hydrophiloidea as often assumed. But the assumption that the three superfamilies constitute a monophyletic "Staphyliniformia" is doubtful. Rather, it appears that the Scarabaeoidea, which are often considered closely related to (but not part of) "Staphyliniformia", share several derived features with Hydrophiloidea and Histeroidea, suggesting that they may be the sister group of these two superfamilies. Staphylinoidea should then be considered as the sister group of Scarabaeoidea, Hydrophiloidea and Histeroidea. Characters defining these groups and supporting hypothesis about their relationships are discussed.

01-199

SEARCHING FOR NEW SYSTEMATIC CHARACTERS IN PALAEARCTIC PACHYDEMINAE (COL., SCARABAEOIDEA)

Isabel Sanmartín & Fermín Martín-Piera

Dpto. de Biodiversidad y Biología Evolutiva. Museo Nacional de Ciencias Naturales (C.S.I.C.). Madrid, ESPAÑA.

Studies on systematics of Pachydeminae have shown an unstable taxonomy. Such instability arises from two closely related facts: i) difficulties in establishing variability patterns (inter or intraspecific) for each character; and ii) many species are poorly represented in the collections, being often limited to the typical series.

This methodological problem is attacked in this work by reviewing the taxonomic goodness of usual characters (mostly external morphology) and by considering new ones (male genitalia). An identification of plesiomorphies and apomorphies has been attempted in all cases. Preliminary results on molecular characters (allozyme electrophoresis) have been obtained too. Until now, 6 genera and 93 species have been studied. In particular, the entire group of genera inhabiting the W-Palaearctic area (except for three monospecific genera) has been analyzed. The average taxonomic sample was 51% species/genus ranging from 30% (*Tanyproctus*) to 100% (*Ceramida*). In all, 24 external characters and 19 concerning male genitalia (genital segment, tegmen and endophallus) are discussed. The results are the following:

i) Male genitalia provides new, useful taxonomic characters and good hypothesis of homology, character states being better defined than in external morphology. Mosaicism in character states is more often found when codifying external morphology.

ii) There are more generic apomorphies (33) than genera to be systematized (14), thus allowing easy and unequivocal identification. The degree of character polymorphism, however, varies among genera determining different species diversity and taxonomical complexity, the greater the polymorphism, the easier the taxonomy.

iii) Allozyme electrophoresis of two populations belonging to different species shows genetic differences congruent with morphological and genitalia homologies.

01-201

PHYLOGENETIC ANALYSIS OF THE NORTH-TEMPERATE SUBGENERA OF *LASIOGLOSSUM* (HYMENOPTERA: HALICTIDAE) USING NUCLEOTIDE SEQUENCE DATA.

B.N. Danforth

Department of Entomology, Cornell University, Ithaca, NY USA

The bee family Halictidae includes over 5000 species worldwide. Within the halictid genus *Lasioglossum* there are roughly 1000 species worldwide. Social behavior in *Lasioglossum* is highly variable among species and ranges from species in which females nest solitarily to species with highly complex forms of social behavior, involving sterile workers, morphologically differentiated queens and workers, and overlap of generations. The high degree of variability in social behavior among the species of *Lasioglossum* makes this group a model system for investigating the origins (and possibly losses) of social behavior in insects. While the monophyly of *Lasioglossum* sensu lato is supported by a number of morphological characters, such as reduced distal wing veins in females and a ventrally directed retrorse lobe in males, the relationships among the 18 currently recognized subgenera of *Lasioglossum* is unresolved. *Paralictus* almost certainly makes *Dialictus* paraphyletic, *Paralictus* + *Dialictus* likely arise from within *Evyllaes*, and *Lasioglossum* sensu stricto may be paraphyletic with respect to *Dialictus* + *Evyllaes*. In order to resolve the relationships within *Lasioglossum*, I have begun generating a preliminary data set based on approximately 1000 bps of Elongation Factor 1- α , a nuclear gene that has a number of desirable traits for higher-level phylogenetic analysis, including an unbiased nucleotide composition, a slow rate of nucleotide substitution, and a low level of homoplasy in phylogenetic analysis. In this talk I will present a preliminary phylogeny for the north-temperate subgenera, including *Lasioglossum* sensu stricto, *Dialictus*, *Evyllaes*, *Sphecodogastra*, *Paralictus* and *Hemihalictus*. Australian, African and Asian subgenera will be added later as more specimens become available.

01-202

THE EVOLUTION OF HABITAT USE AND DIET IN THE SCARABAEOIDEA: A PHYLOGENETIC APPROACH

C.H. Scholtz, S.L. Chown

Department of Zoology & Entomology, University of Pretoria, Pretoria, South Africa

The evolution of habitat use and of diet in the Scarabaeoidea is objectively assessed using character optimization based on a phylogenetic analysis of the superfamily. The ancestral habitat was clearly soil; larval food was microbial- (mainly fungus-) enriched humus; adult food was fungi. The evolution of the major clades is supported by the fossil record. The first major evolutionary event was after the Triassic mass extinction (200 MY) with radiation of the families currently considered to be "primitive" in the Jurassic (180-160 MY). The second major radiation was after the Cretaceous-Tertiary mass extinction (65 MY) when the taxa considered to be "higher" scarabaeoids diversified. The primitive clade is far less diverse than the more modern one. Extinction of taxa in the older clade made way for the diversification of the more modern scarabaeoid groups which was facilitated by the opening of two "new" adaptive zones in the form of the angiosperms and artiodactyl dung. The same themes in the evolution of habitat use and diet are repeatedly played out in both major clades, despite the differences in the floras and faunas of the Mesozoic and the Cenozoic. The phylogenetic tree appears balanced, with respect both to its topology and the ecological characters that are mapped onto it since the clades are virtually mirror images of each other (i.e., similar patterns of habitat use and diet have evolved in the post-Triassic, Mesozoic clade, and the post-Cretaceous, Cenozoic one).

01-204

STUDIES IN THE SYSTEMATICS AND BIOLOGY OF THE EASTERN PALAEARCTIC MORDELLID BEETLES (COLEOPTERA: MORDELLIDAE)

Vladimir K. Odnosum

I.I. Schmalhausen Institute of Zoology, National Academy of Sciences of Ukraine, UA252601 Kiev, Ukraine

By far, the mordellid beetles were poorly examined in the Eastern Palearctic. In 1975-1995, over 7,000 specimens were collected by sweeping and reared by the author. Numerous materials from the most important collections, including primary type specimens, were examined. This work resulted in the revised list of taxa occurring in this area. The further studies of reared materials allow to identify several species of the genera *Tomoxia*, *Hoshihananomia*, *Variimorda*, *Mordella*, *Mordellistena* et al. from larvae.

There are significant affinities in larval morphology and habitats between several species forming groups those include both closely related and non-related species with similar biology; they are recognised as the morphofunctional groups, showing numerous cases of homoplastic characters. They appear independently due to general direction of morphofunctional specialisation in different lineages of Mordellidae. Further, the comparative morphological study of wing structures gives a unique possibility to understand the variability of the wing venation and to hypothesise the ways of their specialisation. Life habits of the Mordellidae are broadly reviewed in the presentation.

01-203

THREE NEW ASIAN GENERA OF FIRE-COLORED BEETLES (COLEOPTERA:PYROCHROIDAE:PYROCHROINAE)

D.K. Young

Department of Entomology, University of Wisconsin, Madison, Wisconsin, USA

When present, cranial pits in adult male pyrochroines may be located behind the eyes, as in *Schizotus*, or between the eyes. In the latter, the pit may consist of a single, shallow impression--as in the European *Pyrochroa* and Asian *Eupyrochroa*--or pits may be well developed and paired as in the North American *Neopyrochroa* and the Asian *Pseudopyrochroa*. **New Genus "A,"** is required for *Pseudopyrochroa sumatrensis* (Pic) (Indonesia, Malaysia-Sabah) + *P. nigripennis* Pic (peninsular Malaysia) + *P. atricolor* Pic (peninsular Malaysia). In this unique assemblage, cranial pits are completely lacking, and the parameres of the male genitalia are very abruptly and widely separated distally.

The monophyly of *Pseudopyrochroa* + **New Genus "B"** may be hypothesized by synapomorphies associated with the external male genitalia. In both taxa, the dorsolateral apices of the parameres are bilaterally toothed, with each tooth projecting basally. The apex of the penis is also provided with a dorsomesal, basally recurved hook. **New Genus "B"** is required for the Vietnamese *Pseudopyrochroa binhana* Pic and several related species presently assigned to *Pseudodendroides*. The structure of the male genitalia precludes placement of these species in *Pseudodendroides*. In *Pseudodendroides* the parameres of the male genitalia are widely separated, distally. This character represents a probable synapomorphy also exhibited by *Neopyrochroa* and **New Genus "C"** (based upon an undescribed species from the Darjeeling District of India).

01-205

SYSTEMATICS OF THE AUSTRALIAN NASUTITERMITINAE (ISOPTERA: TERMITIDAE)

L.R. Müller

CSIRO Division of Entomology, Canberra, Australia

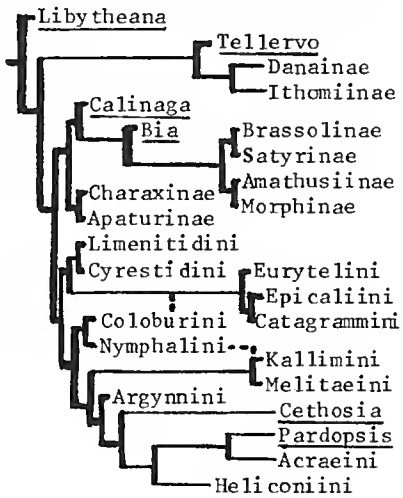

The named species of Australian Nasutitermitinae are currently placed in six genera. The majority of species are distributed between the genera *Nasutitermes* (17 species), and *Tumulitermes* (17 species). This division is unsatisfactory in that different castes of some species may be placed in different genera when considered alone.

A study of external morphology, patterns of mandibular dentition and gut structure indicates that the 34 species belong to at least four genera. This study also reveals that the group is particularly diverse in Australia's arid region, with approximately 40 species awaiting description.

01-206

SYSTEMATICS AND PHYLOGENY OF NYMPHALID BUTTERFLIES (SENSU LATU) BASED ON JUVENILES, WITH AN EXPERIMENTAL STUDY OF THE EVOLUTION OF HOST PLANT PREFERENCE
André Victor Lucci Freitas and Keith S. Brown Jr.
Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, Campinas, São Paulo, Brazil

Nymphalid butterflies are cosmopolitan, comprising about 6000 described species, strongly differentiated into at least five groups morphologically recognizable in all stages, with adults further divergent into about twenty additional groups. The relationships among these groups were investigated through 250 characters drawn mostly from immatures, with an emphasis on Neotropical species (74); 20 Old World species, in isolated or closely related groups, were added to further highlight the divisions and associations. *Libytheana* was initially used as an outgroup, with plesiomorphic character states also checked against other butterfly groups; 11 apomorphies then defined the Libytheinae. The matrix was processed with Hennig86, PAUP, and MacClade with the inclusion of an all-0 hypothetical ancestor. The resulting phylogeny (right) was used to investigate the hypothesis that species are more likely to accept foodplants used by members of more basal branches than those used in branches apical to them. The results in general supported this assumption, especially at the tribal level, but also at the subfamilial level for widely used plant families like Urticaceae, Ulmaceae, Violaceae, Moraceae and Fabaceae. Oviposition mistakes by females also gave clues about possible paths for colonization of new hosts.

01-208

A SYSTEM OF THE LASIOCAMPIDAE (LEPIDOPTERA) OF HOLARCTIC FAUNA

Vadim V. Zolotuhin
Department of Zoology, Ulyanovsk State Pedagogical University

A suprageneric system is proposed for the Lasiocampidae of the holarctic fauna. Type-genera are underlined.

01-207

MORPHOLOGY OF THE PROBOSCIS OF BUTTERFLIES (LEPIDOPTERA: RHOPALOCERA)

HW KRENN, HF PAULUS
Institute of Zoology, University of Vienna, Austria

The extremely elongated proboscis of butterflies has been described only in a few species so far. No comprehensive comparison of the morphology of the proboscis exists and there is no attempt to evaluate the features in functional and evolutionary context.

Using light and scanning electron microscopy, the present investigation of approximately 100 species of butterflies compares the proboscis wall and its surface structures, the inflow-slits-forming structures at the tip, and the form and distribution of the different types of sensilla. The evaluation of the transformation series and the polarity of these features allow the reconstruction of the plesiomorphic character state of the proboscis in Papilionoidea. Divergent evolutionary trends led to distinct combinations of features which characterize the probosces of Papilionidae, Pieridae, and Lycaenidae. Special attention is given to the highly divers probosces of Nymphalidae (sensu lato) and their correlations with specialized feeding habits. The systematical relationships of the subfamilies in Nymphalidae are discussed using proboscis features in addition.

These results contribute to systematical considerations on higher taxonomical level and provide the basis for a better understanding of the functional role of the different structures on the proboscis during flower visiting.

01-209

MICROPYLAR STRUCTURE OF THE EGGS OF SOME SOUTH AFRICAN HEPIALOID MOTHS (LEPIDOPTERA: HEPIALIDAE, PROTOTHEORIDAE)

H. Geertsema
Department of Entomology and Nematology, University of Stellenbosch, Stellenbosch, South Africa

The micropylar area situated at the anterior pole of the lepidopteron egg contains a variable number of micropyles permitting the passage of spermatozoa into the egg. The micropylar area forms part of the chorion and due to its variable nature may be of use as a taxonomic character. The number of micropyles may also be a diagnostic feature. Eggs of four species of hepialoid moths were collected in the Western Cape. Scanning electron microscopic studies indicate distinctive and varying structure of the egg surface and micropylar area of Hepialidae and of Prototheoridae. The surface sculpture of the eggs differ, consisting of small hemispherical protuberances in the Hepialidae and barlike blunt spicules in the Prototheoridae. Micropylar areas were distinctive, differing between the two families, being rounded to subtriangular and consisting of an elevated frame with variable radiating ridges in Hepialidae or only an elevated rim in Prototheoridae. The swollen inner margin encircled a smooth area, two or three micropyles situated equidistant under the inner margin of the frame. The number of micropyles were usually two but in many instances eggs with three micropyles were also present. Studies elsewhere indicate that all hepialoid eggs examined so far only possess two micropyles.

01-210

TEMPERATURE-INDUCED POLYPHENISM IN AFRICAN *BICYCLUS* BUTTERFLIES (LEPIDOPTERA: NYMPHALIDAE): ADAPTATION OR GHOST OF THE PAST?

J.C. Roskam, M. Zandee, P.M. Brakefield

Institute of Evolutionary and Ecological Sciences, University of Leiden, The Netherlands

Temperature-induced variation and norms of reaction have been analyzed for wing pattern elements of six *Bicyclus* species using multivariate statistical techniques. A phylogenetic reconstruction based on adaptive plastic wing characters was compared with a cladogram built on 'non-adaptive' characters.

Results demonstrate that:

(1) Different wing pattern characters are under different control: 'exposed' characters of butterflies at rest position are highly sensitive to temperature variation, whereas 'hidden' characters, only visible during active behaviour, are dominated by species differences. In general the sensitivity of the former can be attributed to their proposed function in deflecting predators.

(2) Phylogenetic distances are to some extent reflected in ordination in both PCA- and DFA-space: closely related species remain close in both ordinations. The more distantly related species differ in ordination from a pattern as suggested by a phylogenetic reconstruction. It is argued that the wing pattern variation of these species reflects both adaptive processes and historical relationships.

01-212

THE PHYLOGENY OF BLATTARIA AND MANTODEA BASED ON MALE GENITAL MORPHOLOGY

K.-D. Klaß

Zoologisches Institut der Ludwig-Maximilians-Universität München, Germany

The male genital organs (phallomeres) of Blattaria and Mantodea are very complex structures supplied with many sclerites and muscles. They are always completely asymmetrical. In Isoptera, the third Dictyopteran order, phallomeres are missing.

By a detailed morphological analysis of the sclerites, muscles and formative elements (in- and evaginations of the cuticular surface) a homology concept for the phallomeres of 4 species of Mantodea and 10 species of Blattaria could be elaborated, and a common ground plan of Blattaria and Mantodea could be reconstructed. Asymmetry is homologous in both orders, and the pattern of phallomere morphology is very similar - in gross structure as well as in many details.

In Mantodea the basal dichotomy is between Mantoididae (not Chaeteessidae) and the other families, in Blattaria it is between Blattidae and the other families. The remaining Blattaria are divided into three groups containing: (1) Tryonicinae (previously assigned to Blattidae); (2) Cryptocercidae, Polyphaginae and Lamproblattinae (the latter previously assigned to Blattidae); (3) Blattellidae and Blaberidae.

Within group (3) Blattellidae are paraphyletic with regard to Blaberidae: Anaplectinae are the basal off-shoot, followed by several branches of Plectopterinae, which are a paraphyletic taxon, too. The higher Blattellidae (Blattellinae, Ectobiinae, Nyctiborinae) and Blaberidae together are a monophyletic group. The phallomeres of Blaberidae and "Plectopterinae" are mirror-images of the phallomeres of other Blattellidae. The hypothesis of Bohn 1987 that this is due to a change of left-right-asymmetry - and not parallel evolution - could be affirmed: For example, *Blaberus* (Blaberidae, phallomeres reversed) is nearly identical to *Nyctibora* (Nyctiborinae, phallomeres normally orientated) in phallomere morphology.

01-211

TAXONOMY AND DISTRIBUTION OF THE GENUS *CALLIPTAMUS* AUD.-SERV. (ORTHOPTERA: ACRIDIDAE)

M.G. Sergeev, I.A. Vanjkova¹, A.A. Pokivajlov²
¹Department of General Biology, Novosibirsk State University, Novosibirsk, Russia - ²Laboratory of Insect Ecology, Institute for Systematics and Ecology of Animals SO RAN, Novosibirsk, Russia - ²Institute of Zoology and Parazytology, Tajikistan Academy of Sciences, Dushanbe, Tajikistan

Taxonomic composition of the genus *Calliptamus* was described by Jago (1963). The phenotypic and morphological analyses permit us to restore a generic status of the *Metromerus* group and to discuss a status of some forms [*C. (italicus) reductus*, *C. (barbarus) nanus*, *M. (coelestriensis) hissaricus*].

The generic range occupies the territory from Spain to the Far East and from North Poland to the Arabian Peninsula. The centers of species diversity of this genus can be observed in the western part of its range.

Some species of this genus (*C. italicus*, *C. barbarus*, *C. turanicus*, *C. abbreviatus*) are the abundant forms in the southern steppes, the semi-deserts and the deserts. Their outbreaks were described for the Mediterranean and Saharan-Gobian regions.

We analyzed the range structures and the local population distribution of these species over biogeographical regions, landscapes and their units. This analysis allows us to develop an idea that every part of a range is characterized by a specific type of dynamics and migrations.

01-213

PHYLOGENETIC RELATIONSHIPS AMONG THE GENERA OF THE JAPANESE HELEOMYZIDAE (DIPTERA)

T. Okadome

Entomological Laboratory, Faculty of Agriculture, Meijo University, Tenpaku-ku, Nagoya, Japan

The Japanese family Heleomyzidae consists of 2 subfamilies (9 genera).

A single genus *Suillia* Robineau-Desvoidy belongs to Suilliinae and the other 8 genera, *Aecothea* Haliday, *Eccoptomera* Loew, *Heleomyza* Fallén, *Morpholeria* Garrett, *Orbellia* R.-D., *Schroederella* Enderlein, *Scoliocentra* Loew and *Tephrochlamys* Loew to Heleomyzinae.

Twelve morphological characters were used in the phylogenetic analysis to reconstruct the relationships among Japanese 9 genera of Heleomyzidae.

Suillia (Subfam. Suilliinae) has mostly modified characters and is more specialized than the other 8 genera of Heleomyzidae.

Among Heleomyzinae, *Tephrochlamys* is more specialized than the rest of genera by the characters of dorsocentral bristles and apicoventral bristles on mid tibia. The other 7 genera, are segregated into 2 branches, *Orbellia* and a group of 6 genera. *Orbellia* has more plesiomorphic characters. In 6 genera, *Heleomyza* and *Scoliocentra* has more plesiomorphic characters. *Aecothea* has more specialized than the 3 genera, *Eccoptomera*, *Morpholeria* and *Schroederella*. These 3 genera are divided into *Eccoptomera* and *Morpholeria* + *Schroederella*, by the chaetotaxy of mid femur. This character state is considered to be plesiomorphic in *Eccoptomera*. The latter 2 genera have synapomorphy in this character.

01-214

BIOCHEMICAL SYSTEMATICS OF THE *PHYLLOTRETA TETRASTIGMA* GROUP OF SIBLING SPECIES (COLEOPTERA : CHRYSOMELIDAE).

P. Verdyck¹, T. Backeljau¹, P. Grootaert¹ & J. Hulselmans²

1 Royal Belgian Institute of Natural Sciences, Brussels, Belgium -
2 University of Antwerp (RUCA), Antwerp, Belgium

P. dilatata Thomson, 1866, *P. flexuosa* (Illiger, 1794) *P. ochripes* (Curtis, 1837) and *P. tetrastigma* (Comolli, 1859) are four closely related and morphologically very similar (sibling) species. All prefer humid biotopes, live on aquatic Brassicaceae, but differ in host plant choice.

In total 13 populations representing the four species were analysed using allozyme electrophoresis of 10 variable loci. For pairwise comparison of populations Nei (1978) unbiased genetic distance and Rogers modified genetic distance (Wright, 1978) were calculated. Trees were constructed using UPGMA and Distance-Wagner methods.

P. ochripes is a clearly distinguished species, *P. dilatata* is separated from *P. flexuosa*/*P. tetrastigma* at the level of sibling species, *P. flexuosa* and *P. tetrastigma* are separated at the level of subspecies. Host plant seem to be important in speciation within this group of species. Our results indicate that host plant shifts followed by genetic differentiation probably are the first steps in speciation in the genus *Phyllotreta*.

01-216

A NEW ARRANGEMENT OF THE GENUS *OTIORHYNCHUS* (COLEOPTERA: CURCULIONIDAE)

L. Magnano
Via Ponte Rofiole, 2, Verona, Italy

Otiiorhynchus presently comprises some 1500 species; their number, however, is presumably much greater. The genus is diffused in the whole central and western Palaearctic, ranging eastwards to Altai Mountains, some species are found in northern Afghanistan, northern India and Nepal. Taxonomy of this huge genus is still confused. According to the art. 11 of the Code, names of the "Artengruppen" proposed by Reitter in 1912 and 1913 must be considered subgenera, although writers have hitherto neglected this rule. The present contribution, which applies the rules of the Code about subgenera of *Otiiorhynchus*, is meant as a first step towards a complete rearrangement of the genus. Following the proposal by Arnoldi, published in 1975 and overlooked by subsequent authors, morphology of *Otiiorhynchus* allow it to be divided in three major groups: the first includes those species with 12 or 13 elytral striae (subgenus *Dodecastichus*), the second comprises species with epipleura straight or only faintly curved outwards at the level of hind coxae (almost all species of the current subgenus *Cryphiphorus*, and those of *Arammichnus* and *Tournieria* in broad sense); the third consists of *Otiiorhynchus* with epipleura strongly curved outwards at the level of hind coxae (nearly all species of subgenera *Limatogaster*, *Tyloderes* and *Cirrorrhynchus*, and those of *Dorymerus* and *Oliiorhynchus* in broad sense). The present study does not support *Trogloorhynchus* be maintained separate from *Otiiorhynchus*: species of *Trogloorhynchus* must be placed in various subgenera. Adults of thermophilous species of *Otiiorhynchus* are found in arid zones under stones, mesophilous and relatively oligothermic ones can also be met under stones, mostly in mountain areas; several mostly criophilous species are related with forests, and can be found on trees and shrubs.

01-2015

COMPARISON OF BIOLOGICAL CHARACTERS BETWEEN TWO KARYOTYPES IN THE *CHRYSOLINA AURICHALCEA* (MANNERHEIM) COMPLEX (COLEOPTERA:CHRYSOMELIDAE).

Shizuo FUJIYAMA
Department of biology, Shinshu University, Asahi Matsumoto, 390 Japan

The *Chrysolina aurichalcea* (Mannerheim) complex is distributed widely in the Palaearctic region and in the species complex, six karyotypes have been already reported. In the Japanese Archipelago, two types of them are widely distributed, although five karyotypes have been reported. In spite of large difference (the 31 type: 2n=31.32 fundamental number=52; the 41 type=41,42 f.n.=70) in karyotype between the two, their biological characters are very similar (e.g. morphological characteristic). To analyze their relationship, further comparison of their biological characters between them was conducted from various view points.

The total complemental length of the two types were compared using their hybrid. The one in the 31 type was almost the same or slightly larger than that of the 41 type. Their developmental zero was quite similar (7.2°C and 6.7°C) but thermal constant was significantly larger (c.a. 40 day-degrees) in the 41 type(c.a. 520 day-degrees from first instar to adult). Their daily rhythm in non-reproductive adult stage was rather different. At the boundary area of both types, the habitat segregation was observed with reference to the plant cover. The seasonal cycles of both types around there were nearly the same but the reproductive season of the 41 type was found to be slightly earlier than that of 31 type.

Based on these findings and other recent studies, I discuss their interrelationships among the types and their evolution.

01-217

DIFFERENT ASPECTS OF SEXUAL DIMORPHISM IN THE COLEOPTERA BRENTIDAE

A. Sforzi, L. Bartolozzi
Museo Zoologico "La Specola", Sezione del Museo di Storia Naturale dell'Università degli Studi di Firenze, Italy

In some brentids sexual dimorphism is absent or very slight, such as in most Cyphagoga Kolbe and Trachelizinae Lacordaire, but it is usually not only obvious but occasionally even striking, affecting various parts of the body: the head (rostrum, mandibles, antennae), pronotum, elytra, legs (femora, tibiae, tarsi), and underside (abdominal plate, last abdominal segment).

The rostrum is usually cylindrical and filiform in the females; in the males it is usually longer (*Brentus* F. spp.) and can be either very dilated apically (*Baryrhynchus* Lacordaire, *Paryphobrenthus* Kolbe), saw-toothed laterally (*Stratiorrhina* Pascoe), with a medial upright protuberance (*Hopliterhynchus* Senna) or markedly pubescent (*Lasiiorhynchus barbicornis* F.).

The male mandibles can be very robust (*Estenorhinus* Lacordaire, *Gyalostoma* Kleine), or long and falcate (*Orfilaia* Haedo Rossi). In male *Bolbocranius czikii* (Bolkay) and *B. distortus* (Westwood) the left mandible is extremely long, flat and sinuate, the right one very small. The use of such an unusual structure is unknown.

The antennae are sometimes much longer in the males, as in *Cerobates* subgen. *Jonthocerus* Lacordaire. In this subgenus the eyes of the males cover almost the entire head. In *Allagopus* Gahan the antennal articles are normally shaped in the males but enlarged and modified in the females; it is one of the rare instances in which the female, and not the male, presents strong structural modifications.

The pronotum is long, slender and narrowed in the middle in male *Brentus anchorago* L., shorter and trapezoidal in the females.

In some species the male elytra have long caudal appendages, short or absent in the females (*Ceocephalus* Guérin-Méneville and in *Phocylides* Pascoe).

The legs of the males often have more or less stout spines on the femora, and sometimes also on the protibiae (*Spatherhinus* Power). In *Cormopus* Kolbe the posterior legs are strongly modified, and differ in both sexes.

The male underside usually has a more or less concave abdominal plate, flat in the females, and a differently shaped last abdominal segment.

Both the function of the structures linked to sexual dimorphism and the use of such structures in understanding the phylogenetic relationships among genera and species are far from clear.

01-218

THE SPERM STRUCTURE OF NEMONYCHIDAE AND URODONTIDAE (CURCULIONOIDEA)

R. Dallai, B.A. Afzelius¹, G. Oscella²

Dipartimento di Biologia Evolutiva, Università di Siena, Siena, Italia -
 1 Department of Ultrastructure Research, Wenner-Gren Institut,
 Stockholm University, Stockholm, Sweden - 2 Dipartimento di
 Scienze Ambientali, Università de L'Aquila, L'Aquila, Italia

Nemonychidae and Urodontidae are plesiomorphic families related to Curculionidae (Thompson, 1992, Kuschel, 1995). By using fixative containing tannic acid (Dallai and Afzelius, 1990) their sperm structure reveals features which fit with the general organization of Curculionidae spermatozoa (Burrini *et al.*, 1988). *Nemonyx lepturoides* shows a trilayered axoneme, a cylindrical nucleus with condensed chromatin material, a centriole surrounded by a centriolar adjunct, an axoneme of 9+9+2 type with accessory microtubules made of 16 protofilaments in their wall and with a central dense axis, two equally sized accessory bodies, one of which connected to a large "puff", two mitochondrial derivatives, which are of unequal size and of which the larger one is fully crystallized and prolonged within a posterior nuclear cavity, a dense thin layer beneath the plasma membrane at the tail end. *Urodon rufipes* shows a sperm structure similar to that described for *Nemonyx*. The main difference deals with the shape of the two accessory bodies. Sperm structure indicates that Curculionoidea have a sperm structure that is maintained throughout the whole group with only small variations in some families. It is confirmed that *Neocoenorhinus aequatus* (Rhynchitidae) spermatozoa have acquired a 9+9+0 axoneme.

The sperm model of Curculionoidea shows synapomorphies with that observed in the related superfamily Chrysomeloidea.

01-220

COMPARATIVE MORPHOLOGY OF THE MOUTH PARTS OF THE SUPERFAMILY CURCULIONOIDEA (COLEOPTERA) AND THEIR RELATIONSHIP TO CLASSIFICATION

J. D. Bae, K. Morimoto

Entomological Laboratory, Faculty of Agriculture, Kyushu University,
 Fukuoka, 812-81, Japan

The group of Coleoptera known as the superfamily Curculionoidea or weevils is of world wide distribution and includes some 60,000 described species which are contained in nine well-defined families.

The most obvious character of the Curculionoides is the prolongation of the head into rostrum, of which the functional significance may fundamentally be the adaptation for drilling the oviposition hole. Ting (1936) and Morimoto (1963) clarified the fundamental structures of the mouth organs, but they discussed with one by one for each part by dissection and not on the compound structures in situ.

Present study is intended to observe the complicated mouth organs in the normal position by SEM and partly under the binocular microscope, and to infer their possible mechanisms of feeding and relationship to classification.

01-219

PHYLOGENY AND HIGHER CLASSIFICATION OF THE WEEVILS OF THE SUBFAMILY RAMPHINAE-COMPLEX (COLEOPTERA, CURCULIONIDAE)

H. Kojima, K. Morimoto

Entomological Laboratory, Faculty of Agriculture, Kyushu University,
 Fukuoka, 812-81, Japan

The weevil subfamily Ramphinae-complex includes following tribes (or subfamilies): Anthonomini, Tychiini, Ochyromerini, Ellescini, Demimaeini, Acalyptini, Derelomini, Ramphini, Dinorhopalini, Anoplini, Eugnomini, Lignyodini and Prionomerini. The definitions of these taxa are various among taxonomists by the lack of conspicuous features. Therefore, the complex is one of the most problematical taxa among the Curculionidae. Although the members of the complex are considered to be closely related to each other, their exact phylogenetic relationships have not been inferred yet.

Present study is aimed to propose a new system of the higher classification based on the inferred relationship from the Asian materials.

01-221

THE PALEARCTIC PERITELINI: THE PRESENT KNOWLEDGE (COLEOPTERA, CURCULIONIDAE, POLYDRUSINAE)

H. Pierotti, C. Bellò

Treviso, Italy - 1. Castelfranco Veneto, Italy

The present knowledge concerning *Peritelini* (Coleoptera, Curculionidae, Polydrusinae), on the faunistic and taxonomical point of view as result of a nine years long field researches are synthetically exposed. Totally 30.000 samples were examined (about 18.000 of them collected by the Authors in all west mediterranean countries) and arranged in 11 genera and 200 species (unpublished included). For each genus the comprehensive number of recognized species and for each country, the *Peritelini*'s number till now described, is reported. Biological, ecological, zoogeographical notes and drawings of the endophallic structures are also added.

01-222

PRESENCE OF STREPSIPTERA LARVAE IN POLLEN COLLECTED BY *APIS MELLIFERA* L. (STREPSIPTERA - HYMENOPTERA: APOIDEA).

G. Bolchi, D. P. Locatelli, M. Colombo, M. Spreafico.
Istituto di Entomologia agraria, Università degli Studi, Milano, Italy.

Strepsiptera first instar larvae are dispersed in the environment and often settle on plants and particularly on flowers where they wait for a host to parasitize. So they may be picked up by workers of *Apis mellifera* L. collecting nectar and pollen from the flowers and incorporated in the pollen loads together with the pollen itself. This is what we have discovered through an examination of samples of pollen taken from hives situated in several localities in the central Italian Alps. The samples were taken by means of special traps, which were inspected weekly from mid-April to mid-September over two consecutive years. The samples thereby obtained were subjected to a filth-test using analytical method especially devised for the purpose, which permitted the extraction of the Strepsiptera larvae from the pollen loads. Most of the samples proved to contain these insects, varying in number according to the season, as shown in the tables here presented. In no case did we observe stylopized bees: this would suggest that the presence of Strepsiptera larvae in the pollen loads is merely a casual consequence of the bees' antophilous behaviour.

01-224

MEDITERRANEAN COLEOPTERA CURCULIONOIDEA WITH SOUTHERN AFRICAN AFFINITIES

G. Osella, E. Colonnelli¹, A. Zuppa
Dipartimento di Scienze Ambientali, Università de L'Aquila, L'Aquila, Italy - ¹ via Nicolò Piccinino 15, Rome, Italy

Some Curculionoidea from the Mediterranean, seemingly evolved in this area, show affinities with taxa distributed in Southern Africa. Among these weevils the number of Southern African species is much larger than that of Mediterranean ones. Genera common to both areas are very few, and no native species are distributed in both regions. There is a low number of genera endemic of Mediterranean, and having Southern African affinities: most of them comprise one or few species, while related genera from Southern Africa usually consist of a larger number of species. Whereas Mediterranean weevils with Paleotropical affinities are more commonly found along the southern border of Palaearctic arid belt, their number is very low in the Pannonic-Sarmatian steppic areas. It can be reminded that some of them can be evenly found in Central Asian arid zones, some also ranging to Pakistan. These weevils apparently preserved similar ways of life as those of their supposed afrotropical ancestors. Apterous or brachypterous Mediterranean Curculionoidea having Paleotropical affinities, which are in addition mostly breeding on hypogeous parts of plants, are generally rather different from Southern African ones. This can be explained by an ancient settlement, and supported by their present relict distribution. Species developing on epigeal parts are usually winged, and in fact they are often differentiated only at specific level, this leading to suppose a more recent diffusion. It is worthy of note that all Aglycideridae, Brachyceridae, and Brentinae (sensu Thompson 1992) from Palaearctic have Paleotropical affinities.

01-223

'WEEVIL SEED PREDATORS OF DIPTEROCARPACEAE'

Christopher H. C. Lyal
Department of Entomology, The Natural History Museum, Cromwell Road, London SW7 5BD, England.

Several genera of Curculionoidea (weevils) include species which feed on seeds of the economically and ecologically important tropical trees Dipterocarpaceae. These beetles can destroy up to 100% of the seeds, and may have been the driving force behind the evolution of mast fruiting of the dipterocarps in South-east Asia. The most speciose genus is *Alcidodes* (Coleoptera: Curculionidae), species of which are pre-dispersal seed predators of several dipterocarp genera. Each species is restricted to a single genus of host, although may be found on many species. Conversely, any one host species may support several *Alcidodes* species.

01-225

INFLUENCE OF *STICHOTREMA DALLATORREANUM* HOFENEDER ON PERFORMANCE OF A TETTIGONIID PEST OF OIL PALM, *SEGESTIDEA NOVAEGUINEAE* (BRANCSIK) (ORTHOPTERA:TETTIGONIIDAE).
T.M. Solulu¹, S.J. Simpson², J. Kathirithamby²
PNG Oil Palm Research Association, P.O. Box 97, Kimbe, WNB, Papua New Guinea - ¹ Department of Zoology, University of Oxford, South Parks Road, Oxford, U.K. - ²

1. Possibility of using *Stichotrema* as biocontrol for *Segestidea* sp., major pest of oil palm, *Elaeis guineensis* in Papua New Guinea (PNG). The strepsipteran endoparasite appears to act as an effective agent in mainland PNG but is absent from West New Britain Province.
2. First stage in establishing whether use of *Stichotrema* as biocontrol agent is feasible is to ascertain the impact of *Stichotrema* on host performance.
3. Poster reports results of work correlating various variables, including gut filling, reproductive development, composition and size of the carcass with the numbers of *Stichotrema* present in field caught sexavae.
4. Results suggest that the presence of *Stichotrema* reduces host feeding and reproductive performances.

01-226

IMMATURE STAGES OF BUPRESTIDAE (COLEOPTERA) - our present knowledge and morphological characteristic.

S. Bílý

Department of Entomology, National Museum, Czech Republic.

With respect to the fact that Buprestids are primary as well as secondary pests and also vectors of tracheomycoses, the attention that has been yet paid to larval morphology and biology of Buprestidae can be considered as minimal.

We can estimate the world Buprestid fauna to be about 12000 species but only larvae of 310 species have been described so far (2.6%). Moreover a lot of old descriptions are inapplicable for taxonomical studies. While nearly 50% of Buprestid larvae from Europe have been described, we know only 2 larvae from the Afrotropical region and 22 from the Oriental region.

From the morphological viewpoint we can recognise 4 morphoecological types: Julodis-type, Buprestis-type, Agrilus-type and Trachys-type. On the basis of larval morphology we can see that some groups are quite artificial (e.g. Trachyinae) and they call for a revision.

01-228

THE LARVAL CHARACTERS OF BUPRESTID BEETLES AND THEIR TAXONOMICAL VALUE (COLEOPTERA: BUPRESTIDAE)

M.G. Volkovitsh

Zoological Institute, Russian Academy of Sciences, St. Petersburg, Russia

The application of larval characters in buprestid systematics is considerably limited by the insufficient knowledge of larval stages as well as by the wide-spread opinion that the evolutionary trends do not coincide on the preimaginal and imaginal stages of ontogeny, and that the larval features are mostly adaptive ones.

Comparative morphological examination has revealed the presence of two groups of larval characters: 1) inadaptive, and 2) adaptive. Inadaptive features are basically determined by the common ancestry and remain nearly constant for the main phylogenetic lineages of buprestids. Adaptive characters are closely related to biological specialization and characterize the morpho-ecological forms of buprestid larvae, which may be closely similar in systematically unrelated taxa. Several related morpho-ecological larval forms can be found within the same genus (for example, *Acmaeoderella*); as this takes place the larvae belonging to different morpho-ecological forms within the same genus are often distinguished much more clearly than the larvae from closely related genera, attributed to the same forms. There are no rigid boundaries between both character categories: the morphoclines of adaptive characters allow to elucidate the evolutionary trends and to clarify the relationship level of different taxa.

The necessity of detailed analysis and evaluation of larval characters and the possibilities of their application to buprestid systematics can be illustrated by the example of some larvae from different phylogenetic lineages which are attributed to the same morpho-ecological forms: leaf miners *Paratrachys* (*Polycestinae*) and *Trachys* (*Trachyinae*), as well as *Pterobothris* (*Buprestinae*) and *Agrilus* (*Agrilinae*).

01-227

PHYLOGENETIC ANALYSIS OF THE "PLEASING FUNGUS BEETLES" (EROTYLIDAE) BASED ON LARVAL MORPHOLOGY.

L. V. McHUGH

Department of Entomology, University of Georgia, Athens, Georgia, U.S.A.

A phylogenetic study of the "Pleasing Fungus Beetles" (Coleoptera: Erotylidae) is presented. The analysis includes 44 erotylid species (representing all five subfamilies) and eight species of the closely related families Languriidae and Cryptophagidae.

The 85 characters used in the study are derived entirely from larval morphology. Despite unique problems posed by this data source, the study finds that larvae represent a rich source of information about phylogenetic relationships in Erotylidae.

Implications of the cladogram for the taxonomy of Erotylidae are discussed. Various aspects of erotylid biology are interpreted within the proposed phylogenetic framework, including pupation behavior and fungus host preference.

01-229

TAXONOMY OF "TRILOBITE LARVAE" GENUS *DULITICOLA* MJÖBERG, 1925 (COLEOPTERA:LYCIDAE) FROM SOUTH-EAST ASIA

T. C. Wong

Department of Zoology, National University of Singapore, Republic of Singapore.

"Trilobite larvae" are the neotenous females of a unique group of Lycidae. Extreme sexual dimorphism is exhibited in that the males are typical lycids while the females retain larval features and grow to many times the size of the males.

Of the three described taxa, only one i.e. *Duliticola paradoxa* from Sarawak, described by E. Mjöberg in 1925, is well known. New species from Peninsular Malaysia and southern Thailand have been described recently. A possible synonymy between *Duliticola* and *Platerodrilus* Pic, 1921 will be discussed. A classification system with more emphasis on female characters will be proposed.

01-230

FIRE-COLORED BEETLE LARVAE OF THE WORLD
(COLEOPTERA:PYROCHROIDAE:PYROCHROINAE):
ANATOMICAL AND MICROHABITAT DIVERSITY

D.K. Young

Department of Entomology, University of Wisconsin, Madison,
Wisconsin, USA

Pyrochroine larvae may be characterized by the presence of a well developed mandibular mola on each of the asymmetrical mandibles, a continuous arch of asperities associated with the anterior margin of the ninth abdominal sternite, and paired urogomphal pits between well developed urogomphi at the distal end of the ninth abdominal tergite. The configuration of the urogomphal plate, including the urogomphi, and urogomphal lip and the urogomphal pits, has yielded a number of important taxonomic features for elucidating relationships at and above the species level.

Larvae are typically associated with mesic conditions beneath slightly loosened bark and to some extent within decaying wood of trees. Although they have been observed to exhibit cannibalism under crowded conditions, they are not normally predaceous, and fungi appear to play a significant role in their diet. In North America, and probably elsewhere, species occupy rather specific microhabitats, thereby partitioning the dead log community and presumably minimizing competition.

01-232

A GENUS OF NEOTROPICAL SEPSIDAE WITH NEARCTIC
AFFINITY (DIPTERA, SCHIZOPHORA)

V. C. Silva

Departamento de Ciências Biológicas, Faculdade de Ciências e
Letras da UNESP, Assis, Brazil

A new genus and species of Neotropical Sepsidae (Diptera, Schizophora), were described based on material from Nicaragua (Silva, 1995). The holotype is preserved in the "Museo Entomologico", Leon, Nicaragua. According to the present classification of the family, gave by Steyskal (1987), the new genus has to be included in the subfamily Sepsinae, tribe Sepsini. The genus is characterized by the following apomorphies: abdomen with two constrictions; the hamate surstylus, free from the hypopygium. It runs to Sepsidomorpha Frey in the key of Steyskal (1987) to all genera of Sepsidae known to occur in the Americas. However, it was took the view of Hennig (1949), making Sepsidomorpha synonym of Sepsis Fallén, into account. It is considered here that the features used by Frey (1908) to characterized this genus, namely, the simple male fore femur and the absence of abdominal macrochaetae, are all plesiomorphies. Steyskal (1987) indicated the need of a new genus for the Nearctic species of Sepsidomorpha. The study of the holotypes of the Nearctic species of Sepsidomorpha (S. brunnipes, S. piceipes and S. secunda), described as varieties of S. secunda by Melander & Spuler (1917), confirmed the view that they are congeneric with this new genus. It is the first Neotropical sepsid genus showing a relationship with the Nearctic fauna. The Neotropical region contains six endemic genera but Meroplius Rondani with a worldwide distribution. The new genus described has few representatives in the Neotropical collections in the same way as the Nearctic species, as stated by Steyskal (1987).

NEW SPECIES OF METEORIDEA ASHMEAD (HYMENOPTERA:
BRACONIDAE, METEORIDELINAE) FROM NEOTROPICAL REGION.

A.M. Penteado-Dias

Departamento de Ecologia e Biologia Evolutiva, Universidade Federal de S. Carlos, S. Carlos, SP, Brazil
The genus Meteoridea is known from the Nearctic (2 species), East Palearctic (1 species), Oriental (1 species), Afrotropical (2 species) and Australian (1 species) regions. The species described here are the first record for the subfamily from Neotropical Region and show that the subfamily extends into temperate regions. They are: Meteoridea whartoni, from Brazil and M. achterbergi, from Brazil and Panama. These species differ from the other species in having discoidal cell sessile, first tergite longer than apical width, 2nd cubital cell narrower above than below, 2nd tergite smooth and the head yellow with the stemmaticum black. M. whartoni and M. achterbergi differ each other by body length and wing venation.

01-233

PHYLOGENETICAL RELATIONSHIPS AMONG CARABUS SPECIES
OF THE SUBGENUS PLATYCARABUS MORAWITZ, 1886
(COLEOPTERA: CARABIDAE: CARABINI).

A. Casale, F. Prueser¹, E. Arndt² & D. Mossakowski¹

Università di Sassari, Istituto di Zoologia, Sassari, Italy - ¹Institute of Ecology & Evolutionary Biology, Universität Bremen, Bremen, Germany - ²Zoological Institute, Universität Leipzig, Leipzig, Germany.

Platycarabus Morawitz, 1886, is a highly homogeneous, monophyletic unit among the section "Lobifera" of the genus Carabus Linné, 1758 (in the widest sense), with five species distributed in montane forests and alpine pastures in several massifs of Central and Eastern Europe. The relationships of these species are extremely close, and this fact is demonstrated, besides morphological characters, by the fact that each is able to hybridize with the others in case of syntopy (rare natural hybrids are known from depressus x cychroides, depressus x fabricii, fabricii x creutzeri, creutzeri x irregularis). Nevertheless, the real phylogenetic relationships among Platycarabus species, sometimes hidden by adaptive features in relation to specialized helycophagous diet, have not so far been clarified.

A cladistic analysis of all Platycarabus species has been conducted, based on both adult and larval characters, the polarity of which has been based on outgroup comparisons (Chaetocarabus Thomson, 1875, Hygrocarabus Thomson, 1875, and a Tribax-like, hypothetical outgroup).

Furthermore, a DNA study was carried out using PCR and sequencing the subunit 1 of the mitochondrial NADH gene. The number of variable positions is low due to the very close relationship of the species.

The aim of this paper is to propose realistic hypotheses about zoogeographical and adaptive processes in Platycarabus based on a tree inferred by morphological and molecular data.

01-234

CLADISTIC ANALYSIS OF THE CARABID BEETLE GENUS *AGONUM* BONELLI FOR THE WORLD (COLEOPTERA: CARABIDAE: PLATYNINI)

Liebherr, J.K.

Department of Entomology, Cornell University, Ithaca, NY, USA

The carabid beetle genus *Agonum* Bonelli possesses a collective Holarctic distribution, with limited species diversity also in the rift mountains of eastern Africa and montane regions north of India and southeast Asia. The genus is characterized, among contribal Platynini, by synapomorphies including an unconstricted neck, and a female spermatheca with duct longer than the apical reservoir. Cladistic analysis utilizing the parsimony criterion was conducted for 129 terminals based on 115 potentially synapomorphous morphological characters. Based on the taxon-area cladogram, the genus appears to have radiated after the Eocene opening of the Atlantic Ocean, as all Holarctic relationships are consistent with Beringean vicariance. The major division in the genus sets the European subgenus *Agonum* plus the Holarctic subgenus *Europhilus* as the sister group to clades distributed in Africa, Asia, Europe, and North America. In general, smaller clades are restricted to limited geographic ranges, however strikingly disjunct sister species also occur: e.g., *A. belleri* Hatch from northwestern North America versus *A. ericeti* Panzer from Europe, and *A. gracilipes* Duftschmid from western Palearctic versus *A. placidum* Say from North America. Relationships demonstrated by the cladogram confirm recent synonymical decisions made by J. Schmidt (Germany). A working subgeneric classification is proposed that is contingent upon examination of the as yet unstudied species.

01-235

A PHYLOGENETIC HYPOTHESIS FOR SELECTED GENERA OF PTEROSTICHINE GROUND BEETLES: IMPLICATIONS FOR LARVAL AND ADULT CHARACTER SYSTEMS

K.W.Will

Department of Entomology, Cornell University, Ithaca, NY, USA

Adult external, male and female genitalic, and larval characters were analyzed cladistically using parsimony methodology for exemplars of nine genera of Pterostichini (Coleoptera: Carabidae), including examples of 15 subgenera of *Pterostichus*. The primarily South American genus *Abaris* was also included in this analysis, the only currently recognized genus of Pterostichini in South America for which the larval form has been described. For the three character systems the relative levels of homoplasy and grouping information was compared. Larval characters are useful for resolving generic level relationships, however, larvae remain undiscovered for most pterostichine genera. Analyses that included genera for which larva are unknown resulted in a loss of resolution. Results from this preliminary study, based on genera for which larval descriptions exist, suggest the polarity and level of stability for various adult character systems in pterostichines. This information was then used to interpret characters in problematic taxa such as *Abropus*, *Metius* and several Australian, African and Asian genera. Results of this study suggest Pterostichini, as presently conceived, is a paraphyletic assemblage relative to other tribes considered to be closely related. A broad and rigorous analysis, that includes multiple character systems, is needed to establish monophyly for a revised concept of Pterostichini relative to putative tribes Loxandriini, and Abacetini, Metiini(=Antarctiini).

01-236

NEW CONSIDERATIONS ON SYSTEMATICS OF PROTURA

W. Y. Yin

Shanghai Institute of Entomology, Academia Sinica, Shanghai, China

Recently, the new findings on comparative morphology and spermatology of Protura were shown that the spermatozoa, the pseudoculi, the female external genital organs and the structure of the alimentary canal are all in three major types. These evidences let us reconsidering the conventional taxonomic system of Protura, and a new system was suggested as the following:

01-237

The Systematics of the Scarabaeoidea (Coleoptera)

D. J. Browne & C. H. Scholtz
Department of Zoology & Entomology
University of Pretoria 0002
South Africa

A study was made of the articulation and base of the hindwings of Scarabaeoidea (Polyphaga: Coleoptera). Relationships among all families and all Scarabaeidae subfamilies are examined for the first time. The reconstructed phylogeny shows that the Scarabaeoidea is comprised of three major lineages: a glaresid, passalid and scarabaeid lineage. The glaresid lineage consists of only the Glaresidae. The passalid lineage is comprised of two major lines: a passalid line (containing Passalidae, Lucanidae, Diphylostomatidae, Glaphyridae, Trogidae, Bolboceratidae and Pleocomidae) and a geotrupid line (containing Geotrupidae, Ochodaeidae, Ceratocanthidae and Hybosoridae). The scarabaeid lineage contains those taxa traditionally included within the Scarabaeidae (Aegialiinae, Aulonocneminae, Aphodiinae, Scarabaeinae, Orphninae, Melolonthinae, *Acoma*, Chasmatopterinae, Hopliinae, Onccrinae, Rutelinae, Dynastinae, Trichiinae, Cetoniinae and Valginae). The importance of wing characters in constructing higher-level phylogenies, instead of employing the "total evidence" approach, is highlighted.

01-238

PHYLOGENY AND EVOLUTION OF THE TRIBE SCAPHISOMATINI (COLEOPTERA: STAPHYLINIDAE: SCAPHIDIINAE)

R.A.B. Leschen¹, I. Löbl²
Department of Entomology, Michigan State University, East Lansing, MI USA - 2 Muséum d'Histoire naturelle, Entomologie, Genève, Switzerland

Leschen and Löbl (1995) examined the phylogenetic relationships of the fungus feeding staphylinid subfamily Scaphidiinae (consisting of the tribes Cypariini, Scaphiini, Scaphidiini, and Scaphisomatini). In their study, however, Scaphisomatini was treated superficially and was represented in the data matrix by two terminal taxa. We conducted a preliminary cladistic study of Scaphisomatini (which includes about 35 described genera) by including two genera from each of the subtribes (Heteroscaphina, Baecoceridiina, Baecocerina, Scaphisomatina, and Toxidiina). This analysis, based on 11 terminal taxa (including a generalized outgroup) and 34 characters, resulted in three parsimonious reconstructions of relationships. Each of these show that all subtribes are polyphyletic with the exception of Baecoceridiina which in two trees are monophyletic and sister taxon to *Scaphisoma* (Scaphisomatina). These data suggest the current classification is unsatisfactory and must be changed to reflect natural groupings. Our results are interesting because most members of Baecoceridiina are associated with Old World termites suggesting that the evolution of social insectinquilism may have evolved one time in the subfamily.

01-240

A CATALOGUE OF ORIBATID MITES (ACARIDA, ORIBATIDA) OF THE ARGENTINA REPUBLIC

G. Velis and P. Martinez
Laboratorio de Artrópodos. Fac. Cs. Exactas y Naturales. Univ. Nac. de Mar del Plata
Funes N° 3350 (7600) MAR DEL PLATA. Argentina. FAX (023) 749009

The knowledge of the oribatologic fauna of the Argentina republic starts in the beginnings of the last century, in a disorganized way with general studies. In this way are described more or less 40 species essentially from La Plata, Tierra del Fuego, Antartida and Islas subantarticas. Unfortunately the material is not conserved in a good way or the description are incomplete making unused a great majority of them. A second stage in this study come with Marie Hammer investigations along the Cordillera de los Andes, who collected and described material in Salta, Mendoza and Patagonia (Hammer, 1958, 1962). By the same time (Balogh and Csizsar, 1963) described material collected by Topal in El Bolson (Rio Negro). Between 1966 and 1967 Balogh lead the first expedition Hungara of Zoology of southamericans soils, collecting in our country, in Tanti, Sierras de Cordoba (Balogh and Mahunka, 1968). This second stage increased the knowledge of the oribatid mites in our country, counting more or less 140 species, lots of them knew for the science. In the following decades start the work of local acarologists, still in process, with description of species of Mendoza (Fernandez 1987), and the provincia of Buenos Aires (Baranek, Alzuet, Fernandez) principally. The objective of the present work is to present a list of the species of oribatid mites founded up to the present in our country, knew or not, to be used as a starting point, for future investigations. For this, we took as base the work of Balogh and Balogh of 1988, adding those species that for having being published in magazines of local circulation had not been considered, as those had being described with posteriority to its publication.

01-239

UNCOVERING THE RADIATION OF NEW ZEALAND'S ONYCHOPHORA USING MOLECULAR DATA.

D. Gleeson
Manaaki Whenua- Landcare Research,
Private Bag 92170, Auckland New Zealand.

The Onychophora are an ancient Gondwanic group which have been described as the missing link between arthropods and annelids. In New Zealand, five species of Onychophora, belonging to two genera have been formally described. Four species within the *Peripatoides* genus are endemic, with the oviparous *Ooperipatellus insignis* also found in Victoria, Australia. The genus *Peripatoides* is distinctive from all Australian genera but shares features with two other genera, one from Chile, and the other from New Guinea. Morphological taxonomy has proven difficult with this group as few non-conflicting characters exist. However molecular data in conjunction with further morphological information has indicated that New Zealand supports more species than are currently recognised. This talk presents the phylogenetic relationships within the New Zealand Onychophora based on current molecular data. The biogeographic implications of these relationships will also be discussed.

01-241

PHYLOGENY OF THE GENERA OF THE ALEOCHARINE TRIBE MYLLAENINI AND RELATED GROUPS (COLEOPTERA: STAPHYLINIDAE: ALEOCHARINAE)

J. S. ASHE
University of Kansas Natural History Museum, Lawrence, Kansas, USA

Phylogenetic analysis based on adult morphological characteristics provides strong evidence that the genera of the tribe Myllaenini (5 genera, including 2 previously undescribed ones) as well as several genera currently placed in the Diglottini and Pronomaeini form a monophyletic lineage. This lineage is confirmed to be a very early branch of the "higher aleocharines" with which its members share the presence of a tergal gland that opens on the anterior margin of abdominal tergum VII. The Myllaenini are not closely related to the Gymnusini and Deinopsini as proposed by some; however, the phylogeny provides considerable insight into character evolution among basal lineages of aleocharines.

01-242

A REMARKABLE BRACHYPTEROUS FEMALE OF DILARIDAE
(*DILAR PARTHENOPAEUS* COSTA ?) (NEUROPTERA)R. A. Pantaleoni, A. Letardi¹Institut of Agricultural Entomology, University of Sassari, Italy
¹ ENEA Casaccia, Rome, Italy

In July 1992 one brachypterous female of Dilaridae was found in a pitfall trap placed in holm-oak wood on Lepini Mountains (Latium, central Italy)*. In the same trap, 4 males were collected too. They belong to the taxon *Dilar parthenopaeus* Costa, 1855. Up to now the female of this species was unknown.

This female specimen (about 6 mm long, ovipositor included), is utmostly more massive than male: head, torax and abdomen were shorter and stouter. The three tubercles on vertex are much more developed whereas eyes are smaller than male one's. The flagellum of antennae is 20-segmented. Mouthparts are well developed. Fore wing (about 4 mm long) is clearly convex, unfit for flight, with thickened membrane and simplified venulation, fainted in medial space. Only one black horny spot (nygma) between MA and MP. Pigmentation stronger and sharper than male one's. Hind wing (about 0,5 mm long) is reduced to a small sub-triangular membranous scale with some veins just outlined. Legs are just a little shorter than male one's.

Life history of this species remains completely unknown.

Presence of brachypterous females with short mobility could have remarkable consequences on population biology of Dilaridae with geographic isolate of uncertain taxonomic range. From there, the hypothesis that *Dilar parthenopaeus* s.l. could be a group of sibling species (or subspecies), as recently advanced (U. & H. Aspöck, 1995 - *Dilar duelli* n. sp. - Z. ArbGem.Österr.Entomol.; Principi & Pantaleoni, 1995 - Checklist delle specie della fauna italiana. 62), is further strengthened.

* In the frame of Researches on Forest Entomocoenosis of central Italy, Dip. of Animal and Human Biology, Univ. Roma, Prof. A.Vigna Taglianti & coll.

01-244

THE PHYLOGENETIC TREE OF HOLARCTIC GENERA OF DIAMESINAE AND PRODIAMESINAE

B. Rossaro and M. Framarin

Department of Biology, Section Ecology, University of Milan, Milan, Italy

The phylogenetic tree of the holarctic genera belonging to the subfamilies of Diamesinae and Prodiamesinae (Diptera, Chironomidae) using all 3 metamorphic stages (larvae, pupae and adult males) is revised. The phylogenetic relationships between genera are still uncertain. Homologies of the hypopygial appendages (aedeagal lobes, volsellae) between the 2 subfamilies are not yet established. It is not yet clear whether basal plate and median field sensu Hansen & Cook (1976) described within the Diamesinae are homologous or not to superior and inferior volsella described within the Prodiamesinae. Phylogenetic reconstruction's are based on male adult morphology, pupal morphology is sometimes included to support conclusions based on adult males. Larval morphology is often not considered in phylogenetic studies, even if the larvae of many genera are still described. The importance of female genitalia is a questioned point. At present phylogenetic relationships based on all semaphoronts are recommended. Some questions are here discussed: the relationships between the genera belonging to the 2 subfamilies and the genera *Pseudodiamesa*, *Diamesa* and *Lappodiamesa*. According to Serra Tosio (1967) *Lappodiamesa* and *Diamesa* are more closely related to each other than with *Pseudodiamesa*, the same point is not shared by Saether & Willassen (1988) that describing the larva of *Lappodiamesa* emphasise the affinity between *Lappodiamesa* and *Pseudodiamesa*. In the present study 120 characters from 19 holarctic genera belonging to larvae, pupal exuviae and adult males are considered. As a preliminary approach a numerical taxonomy study has been carried out to reveal the relationships between genera.

01-243

A COMMUNITY PARASITOID WEB: GALLMIDGES (DIPTERA: CECIDOMYIIDAE) ON *SALIX* SPP. (SALICACEAE). I. STRUCTURE OF THE PARASITOID COMMUNITY

J. Amendt

Forschungsinstitut Senckenberg, Frankfurt, Germany

Within the scope of the research-project „Structure and dynamics of phytophagous systems on *Salix* spp.“ the parasitoid community of eight gallmidge species on willow were analyzed. 7 host species belong to the genus *Dasineura*, formerly *Rabdophaga*, and 1 host to the genus *Iteomyia*. The plant galls were collected on about 25 different localities in Germany, Denmark, Swiss and Italy in the season of 1994/95. During that period 25 Chalcidoidea and at least 5 Platygastroidea were reared.

Most of the chalcid parasitoids seems to be idiobiont species (do not permit the host to grow after parasitization) but more examinations could raise the real part of Koinobionts (allow their hosts to continue to feed and develop after parasitization) in the community. 92 % of the chalcid species parasitized just one of the investigated hosts. The genus *Aprostocetus* dominate the community and is represented by 10 species.

The Platygastroidea are Koinobionts. All *Dasineura* spp. are parasitized by them. Their taxonomic situation is difficult but all of them belong to the 3 genera *Platygaster*, *Inostemma* and *Synopeas*.

Further investigations will examine the structure and organization of the different guilds (e.g. leaf-galls versus stem-galls) over at least three years and the response of the parasitoid community to host population dynamics. The final goal is the construction of a quantitative parasitoid web dealing with gall-inducers on *Salix* spp.

01-245

THE PRELARVAE OF ORIBATIDS MITES
(ACARIDA: ORIBATIDA)

G. Velis

Laboratorio de Artropodos. Fac. Cs. Exactas y Naturales. Universidad Nac.de Mar del Plata. Funes N ° 3350 (7600) MAR DEL PLATA. ARGENTINA

The knowledge of the existence of prelarvae in Oribatid mites, date back to 1855, when Nicolet describe them for the first time. Claparede in 1868, and Michel in 1884 and 1888, who drew other prelarvae (under the name of deutovum).

A series of studies commenced in 1938 with the work of Grandjean. The definition of the calyptostase was created (Grandjean, 1938, 1954, 1958, 1962); Van der Hammen, 1963, Lions, 1967, 1968, 1971, 1973). In spite of their importance as far as evolutive and phylogenetic studies are concerned, our knowledge at present is still fragmentary, only works in Argentina the Fernandez et al, 1991 and Velis in press.

Morphological survey was carried out the inferior and superior oribatids mites prelarvae. It was discussed that discordant evolution is consistent with life-span as adaptative strategy. Discussion was also made on character evaluation of prelarvae.

01-246

REVISION AND TRANSFERENCE TO RHOPALOPHORINI (COLEOPTERA, CERAMBYCIDAE, CERAMBYCINAE) OF THE GENERA *COREMIA* A.-SERVILLE, 1834 AND *MEROCOREMIA* MARQUES, 1994.

M.I. MARQUES, D.S. NAPP¹

Instituto de Biociências, Departamento de Biologia/Zoologia, Universidade Federal de Mato Grosso, Cuiabá Mato Grosso, Brasil- ¹ Departamento de Zoologia, Universidade Federal do Paraná, Curitiba Paraná, Brasil.

A detailed morphological comparative study of the species up to now included in the genus *Coremia* together with *Merocoremia* and representatives of Rhopalophorini and Compsocerini showed: 1) significant differences among the present recognized *Coremia* subgenera; 2) the closer affinity of *Merocoremia* and of the subgenera of *Coremia* to the Rhopalophorini genera *Rhopalophora* and *Cosmisoma*, the similarities with *Compsocerus* and allied Compsocerini genera being symplesiomorphies. Thus the present subgenera of *Coremia* are being ranked to the genus status and transferred to Rhopalophorini together with *Merocoremia*. The genera *Coremia* A.-Serville, 1834, *Dirocoremia* Marques, 1994, stat. n., *Thalusia* Thomson, 1864, stat. n., *Lathusia* Zajciw, 1959, stat. n. and *Merocoremia* Marques, 1994 are redescribed including characters of the mouth pieces, endosternites, wing venation, empodium and male and female terminalia. In spite of the differences observed among these genera, a set of apomorphic character states is shared by the here called *Coremia* group and may probably indicate its monophyletic condition within Rhopalophorini. A key to the genera and species is added.

01-248

RECONSIDERATION OF THE SYSTEMATIC POSITION OF FOUR SPECIES OF *CYRTONEURINA* GIGLIO-TOS, 1893 (DIPTERA, MUSCIDAE)

D. Pamplona

Departamento de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brasil

Among the forty-seven species listed in Carvalho et alii 1993, a catalogue of the Muscidae of the neotropical region, the following four species mentioned have a new status. Holotypes, syntypes and specimens compared with the types were examined as part of a study of the whole genus and every morphological character used was taken into account. The new combination *Cyrtoneurina bequaerti* (Aldrich), 1932 is not a *Cyrtoneurina* as it has striking differences, and for instance can be cited: anepimeron well setulose; setae below the lateral bristles of the scutellum absent; dm-cu strongly curved; arista with short hairs; body length more than 7,0 mm. *Cyrtoneurina stellata* Couri, 1892 is actually *Polietina* Schnabl & Dziedzicki, 1911 as it has also remarkable differences with *Cyrtoneurina* for example: gonopod is too big in proportion to the dimension of gonopod; distiphallus is too big; cercal plate has spines, typical of *Polietina*; 3 notopleural bristles; calyptra setulose. *Cyrtoneurina geminata* (Stein), 1904 is not a synonym of *Cyrtoneurina gemina* (wiedemann), 1830 as it has a prosternum bare; R₁ dorsal and ventral surface bare; dm-cu straight; about 14 hairs on arista; midtibia at anteroventral surface without bristle on medium third.

01-247

BIOCHEMICAL SYSTEMATICS OF TINEIDAE (LEPIDOPTERA)

M.A. Cook, L.M. Harwood¹, G.S. Robinson²

International Institute of Entomology (An Institute of CAB International), London, U.K. ¹ Department of Chemistry, University of Reading, U.K. ² Department of Entomology, The Natural History Museum, London, U.K.

Although analysis of DNA has had a profound impact on biosystematics, the potential of other biochemical systems has not been thoroughly investigated. Yet, insect cuticles contain complex mixtures of organic molecules that are potentially useful taxonomic characters. The few studies that there have been of these low-volatility, long-chain organic molecules have highlighted their potential contribution to taxonomy but have left a very incomplete picture of their distribution in the Lepidoptera.

A group of marker compounds were extracted from Tineidae and analysed using Gas Chromatography-Mass Spectrometry (GC-MS). Area normalised chromatogram peaks were used to derive a quantitative measure of marker compounds in individual specimens and statistical analysis used to analyse patterns of their occurrence at individual, species, generic and higher taxonomic levels. These patterns are discussed and assessed against phylogenetic evidence from morphological characters.

01-249

DENSITY-RELATED INTERACTIONS AMONG GALLING INSECTS

Christer Björkman and Weronika Linkowski

Department of Entomology, Swedish University of Agricultural Sciences, P.O. Box 7044, S-750 07 Uppsala, Sweden

Many galling insects seem to have a limited capability to disperse. This often leads to high local densities at different scales, for example, on a plant, a branch or a leaf. In this study we have surveyed how density affects performance of galling insects in six different systems: cecidomyiids on aspen, cynipoids on oak, a cecidomyiid and a tenthrinid on Salix and an adelgid on spruce. Gall size was the performance parameter studied in all systems. In some systems we also studied the effect of density on survival of insects initiating the gall. The plant unit studied in most systems was single leaves, but included in some also larger spatial scales. Our data indicated that, in some systems, there could be a positive effect of density on performance up to a certain point, beyond which the relationship became negative. Preliminary results on the relative strength of intra- and interspecific competitive interactions are also presented. Possible mechanisms behind and consequences of these cooperative and competitive interactions among galling insects are discussed.

01-250

THORACIC SCLERITES: ADDITIONAL INFORMATION CONCERNING THE BASAL EVOLUTION OF DIPTERA (INSECTA)

D.S. Amorim¹, F. Bravo¹, E. Collucci²

Depto. de Biologia, FFCLRP, Universidade de São Paulo, Ribeirão Preto SP, Brazil - 1 Curso de Pós-Graduação em Entomologia, Universidade Federal do Paraná, Curitiba PR, Brazil - 2 Curso de Pós-Graduação em Entomologia, Universidade de São Paulo, Ribeirão Preto SP, Brazil

Thoracic sclerites of different basal families of Diptera were studied. They presented useful information concerning the discussion about the phylogenetic relationships among the basal stems of Diptera. The most helpful feature is the meron, which may be attached to the mid coxa (plesiomorphic) or separated from the coxa, fused in various degrees to the thoracic sclerites (apomorphic). The Tipulomorpha—including Tipulidae and Trichoceridae—and the Bibionomorpha—including Pachyneuridae, Cramptonomyiidae, Anisopodidae, Bibionidae and the Mycetophiliformia—are plesiomorphic for this fusion. A meron fused to the thoracic sclerites is clearly seen in the Ptychopteromorpha, Psychodomorpha (without Trichoceridae and Anisopodidae), Culicomorpha, Axymyiomorpha and Brachycera. This partially agrees with previous phylogenies, especially displacing the Scatopsoidea, Perissomatidae and Axymyiidae from the Bibionomorpha to other stems and in the more basal position of the Bibionomorpha in the phylogeny of the Diptera. Apomorphic modifications exclusive of the Bibionomorpha indicate the possible monophyly of the group. A fusion of the epimeron I with the mesothorax may be a homologous achievement of the Scatopsoidea and the Brachycera, indicating that the "Psychodomorpha" may correspond, as recently suggested, to a merophyletic arrangement.

01-252

CLADISTIC ANALYSIS OF SCIOMYZIDAE FALLÉN, 1820 (DIPTERA)

L. Marinoni

Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brasil

A previous analysis is presented in order to define the phylogenetic relationships among the genera of the family Sciomyzidae which has a worldwide distribution. The monophyly of Sciomyzidae is based on the habit of malacophagy of the larvae.

The analysis was performed using the program Hennig86. Thirty six morphological and one behavioral character were used to analyse the sister-group relationships among fifty genera.

In the analysis using the successive weighting option, six cladograms were obtained. One consensus cladogram is presented.

The subfamilies Salticellinae and Sciomyzinae and the tribes Sciomyzini and Tetanocerini are monophyletic.

01-251

THE PHYLOGENETIC VALUES OF THE DIFFERENT APPROACHES IN THE HOVERFLIES (DIPTERA: SYRPHIDAE) CLASSIFICATION

S. Glumac, A. Vujčić

Institute of Biology, University of Novi Sad, Novi Sad, Yugoslavia

The hoverflies are one of the largest families of the Diptera with more than 5500 already described species. Syrphids are well known for their acrobatic fly and hovering, mimetic coloring and visiting flowers for nectar and pollen. Larvae have extremely diverse feeding habits, with species being saprophages, zoophages and phytophages. This great diversity makes the family very attractive for testing ideas about the evolution of different strategies of development. Many authors deal with problem of hoverflies phylogeny having different approaches in consideration of division and relationship within hoverflies groups. This work concerns the values of different characters used in the hoverflies systematics: adult morphology, especially male genitalia structure, larval morphology, type of larval development, centers of groups origin, etc. We try to emphasize the importance of differences between characters with low and great level of adaptability values.

01-253

THE PHYLOGENETIC POSITION OF THE BAT-FLY FAMILY (DIPTERA: MYSTACINOBIIDAE) FROM NEW ZEALAND.

D. Gleeson

Manaaki Whenua - Landcare Research, Private Bag 92170, Auckland, New Zealand.

A new species of bat-fly, *Mystacinobia zelandica*, was described in 1976 (Holloway, 1976). This fly is flightless with reduced vision and has claws that allows movement over the bat's fur but does not possess mouthparts enabling the piercing of skin. Instead the adults and larvae feed on guano of the New Zealand lesser short-tailed bat *Mystacina tuberculata*. The adults cling to the bat's fur in order to disperse to new roost sites. This species has a level of group sociality not observed in other Diptera including group oviposition, clustering of all stages, mutual grooming, and extension of the male's life-span beyond the reproductive phase to form a sound-producing guard caste.

It is clear that this species does not belong to any blood-feeding Streblidae or Nycteribiidae, nor any other known family of Diptera. Therefore *M. zelandica* exists as the sole representative of its genus and family Mystacinobiidae. Morphological features suggest that this species belongs among the acalypterates with many drosophiloid features hence its current position within the superfamily Drosophiloidea. However, the many novel features which required a new family to be erected have also placed some question as to the phylogenetic position of this family within the Drosophiloidea. Molecular characters have been used to help solve this issue and determine the origin of this distinctive member of New Zealand's unique endemic fauna.

01-254

CLADISTIC ANALYSIS OF SCIOMYZIDAE FALLÉN, 1820 (DIPTERA)

L. Marinoni

Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brasil

A previous analysis is presented in order to define the phylogenetic relationships among the genera of the family Sciomyzidae which has a worldwide distribution. The monophyly of Sciomyzidae is based on the habit of malacophagy of the larvae.

The analysis was performed using the program Hennig86. Thirty six morphological and one behavioral character were used to analyse the sister-group relationships among fifty genera.

In the analysis using the successive weighting option, six cladograms were obtained. One consensus cladogram is presented.

The subfamilies Salticellinae and Sciomyzinae and the tribes Sciomyzini and Tetanocerini are monophyletic.

01-256

BIODIVERSITY AND BIOGEOGRAPHY OF THE UPDATED CHRYSOMELID FAUNA OF BALEARIC ISLANDS (COLEOPTERA)

A. Sacarés¹, J. Gómez-Zurita² and E. Petitpierre²

¹ Museu Balear de Ciències Naturals, Sóller (Balears), Spain.

² Laboratori de Genètica, Facultat de Ciències, Universitat de les Illes Balears, Palma de Mallorca, Spain.

The chrysomelid fauna of the six larger islands of the Balearic archipelago is updated. The biodiversity and similarity between islands are quantitatively measured. A particular emphasis is given to the five endemic species so far recorded.

01-255

A NEW BEETLE (*AFROCUPES FIRMAE*) (PERMOCUPEDIDAE) FROM THE UPPER PALAEOZOIC WHITEHILL FORMATION OF SOUTH AFRICAH. Geertsema, J.A. Van den Heever¹

Department of Entomology and Nematology, University of Stellenbosch, Stellenbosch, South Africa - ¹ Department of Zoology, University of Stellenbosch, Stellenbosch, South Africa

An extensive array of Permian cupedoid beetles is known from Russia and Czechoslovakia. To date only one cupedid beetle, *Moltenocupes townrowi*, from the Triassic Molteno Formation of South Africa and two permocupedid beetles from the Permian Irati Formation of Brazil have been described. Here a further permocupedid beetle, *Afrocupes firmae*, from the Permian Whitehill Formation of South Africa is reported. The Whitehill Formation is the temporal and lithological equivalent of the Irati Formation and the discovery of *A. firmae* provides further proof of the Parana-Karoo Basin linkage. *A. firmae* is the oldest beetle yet found on the African continent. The paucity of fossil insects from the Whitehill Formation is briefly discussed.

01-257

NEW SPECIES OF *CALYCOMYZA*, *JAPANAGROMYZA* AND *GALIOMYZA* (DIPTERA: AGROMYZIDAE) FROM BRAZIL.

Esposito, Maria Cristina. Departamento de Zoologia, Museu Paraense Emílio Goeldi, Belém, PA, Brazil.

Five new species are described from Brazil: *Calycomyza unicampensis* and *Calycomyza genebrensis*, mining leaves of *Ipomoea batatas* (R.) Poir. (Convolvulaceae); *Calycomyza ipomoensis*, mining leaves of *Ipomoea asarifolia* (Desr.) Roemer & Schultes (Convolvulaceae); *Japanagromyza macroptilivora* mining leaves of *Macroptilium latyroides* (L.) Urban. (Fabaceae) and *Galiomyza richardii* mining leaves of *Richardia brasiliensis* Gomez (Rubiaceae). The *Galiomyza* genus is recorded for the first time in Brazil.

The study indicates the importance of a number of characteristics which, alone or in combination, facilitate the identification of agromyzid species. The most important of these are the morphological characters of the male genitalia, larval behaviour (form and location of mines, appearance of the frass and pupation sites) and the plant species attacked.

01-258

A NEW SPECIES OF *RHYACOPHILA* Pictet, 1834 FROM SOUTHERN ITALY (INSECTA TRICHOPTERA: RHYACOPHILIDAE)

G.P. Moretti

Istituto di Zoologia, Facoltà di Scienze MM.FF.NN. Università di Perugia. Italy

Rhyacophila vallei n. sp.

Holotype ♂, allotype ♀: Calabria, Gole del Raganello, Civita, 400 m a.s.l., 29.VII.1993, coll. Pantini, Valle. At the Natural Science Museum of Bergamo. Paratypes 2 ♂, 4 ♀ in Moretti's collection at the Zoology Institute, Perugia University.

Male: antennae, palps, legs pale. Wings yellowish with small brown spots. Length of forewing 10 mm.

Genitalia: dorso-apical lobe of segment 9 long, slightly downturned. Upper body of segment 10 dark. Aedeagus curved and apically hooked. Parameres elongated, bifid at the apex with a preapical tooth. Second segment of gonopods markedly concave with strongly protruding inferior lobe covered with thick dense spines on the apical surface.

It is close to *Rhyacophila tarda* Giudicelli from Corsica.

Female: length of forewing 12 mm. Genitalia: at the proximal part of segment 8 a sclerotized collar with a shallow dorsal and ventral split. Spermathecal sclerite elongated club-shaped. Apex of segment 10 bilobed with two short cerci. Last instar larva: length 12 mm. Pale with dark marbling on the abdominal tergites. Head and pronotum with a few small brown spots. Posterior margin of the pronotum large and black. Gills with four filaments each divided by a constriction. Anal prolegs with sabre-like projection, claw with two small teeth.

The species is named after my friend Dr. M. Valle, esteemed Curator of the Natural Science Museum 'Caffi' of Bergamo.

01-260

A NEW CHARACTERIZATION OF *CYRTONEURINA* GIGLIO-TOS, 1893 (DIPTERA: MUSCIDAE)

D. Pamplona

Departamento de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brasil

In the original description and in the subsequent work, in 1895, Giglio-Tos defined *Cyrtoneurina* with few characters, almost general ones. Other authors that studied this genus, described species and even biological aspects (e.g. Malloch 1925 and Ségué 1937) but it was Snyder 1954 the first author to give a complete definition of *Cyrtoneurina* and to compare it to the related genus. In the present work several characters were used for the diagnosis of the genus and the main ones present in the greater number of the species are: eyes bare or with discrete ciliation among the ommatidia; arista plumose with 9-30 long hairs, with secondary pilosity; Dc 2:4, 2:3; setae below the lateral bristles of the scutellum; prosternum bare, with fine pubescence or setulose; katepimeron bare or setulose; R₁ and R₄₊₅ dorsal and ventral surface setulose; M₁₊₂ not strongly curved towards R₄₊₅; midtibia at posterior surface with two bristles; hindfemur at anteroventral surface with two or three bristles on apical third; hindtibia at anterodorsal surface with one or two bristles; wing spotted or not; angulation on apical half of sternite V present or absent; surstylus bare or setulose, with the tip near or well far from the apex of the cercal plate; eedeagus spines present or absent; ovipositor long or short; epiproct bare or setulose with two bristles; tergites broad or narrow.

01-259

SOME NEW COCCINELLIDS (COL. : COCCINELLIDAE) SPECIES FROM IRAN.

Mossadegh, M.S.; M.R. Bagheri; N. Koochpayehzadeh; S. Moodi and M.M. Montazeri.

Department of Entomology, College of Agriculture, Shahid Chamran University, Ahwaz Iran.

In 1989-1995 during a faunistic survey for coccinellids in 5 provinces (North, Northeast, Central and southwest) of Iran, altogether 61 species belong to 25 genera from 12 tribes and 6 subfamilies were collected and identified. Among the collected coccinellids, 12 species were new records for Iran as follows:

I- Subfamily: Scymninae

a- Tribe-scymnini

- 1- *Scymnus* (*Scymnus*) *inderihensis* (Mulsant)
- 2- *Scymnus* (*Scymnus*) *levaillanti* (Mulsant)
- 3- *Scymnus* (*Pullus*) *argutus* (Mulsant)
- 4- *Nephus* (*Sidis*) *biguttatus* (Mulsant)
- 5- *Nephus* (*Sidis*) *biflammulatus* (Motschulsky)
- 6- *Nephus* *ulbrichi* (Fursch)
- 7- *Diomus*? *rubidus* (Motschulsky)

b- Tribe-Hyperaspini

- 8- *Hyperaspis* *polita* (Weise)
- 9- *H. concolor* (Suffrian)
- 10- *H. duvergeri* (Fursch)

II- Subfamily: Sticholotidinae

Tribe-serangini

- 11- *serangium montazeri* (Fursch) n. sp.

III- Subfamily: Coccidulinae

Tribe-Novini

- 12- *Nephus fenestratus* (sal.)

The coccinellids prey on aphids, spider mites, coccids, and whiteflies.

01-261

PHYLOGENETIC RELATIONSHIPS WITHIN THE CULICOMORPHA INFERRED FROM 18S AND 5.8S RIBOSOMAL DNA SEQUENCES (DIPTERA: NEMATOCERA)

B.R. Miller¹, M.B. Crabtree¹ and H.M. Savage²
¹Virus and Vector Molecular Biology Section, ²Epidemiology and Ecology Section, Arbovirus Diseases Branch, Division of Vector-Borne Infectious Diseases, National Center for Infectious Diseases, Centers for Disease Control and Prevention (CDC), Public Health Service, U.S. Department of Health and Human Services

We examined the evolutionary origins of mosquitoes by sequencing the entire 18S and 5.8S genes in the nuclear, ribosomal gene array of twelve nematoceran taxa. Maximum parsimony analysis and distance analysis with neighbor-joining demonstrated that a phlebotomine sandfly formed the most basal lineage when a tipulid was used as an out-group. Within the Culicimorpha, corethrellids, chabborids and culicids formed a monophyletic group. Phylogenetic relationships among dixids, chironomids, simuliids and ceratopogonids were unresolved although there was weak support for a sister relationship between the dixid and simuliid. Lack of a spacer in the 5.8S gene was an autapomorphic character among the four genera of Culicidae examined in relation to their sister group, the Chaoboridae. Within the Culicidae, Toxorhynchites was the sister group to an Aedes-Culex clade. The genus, Anopheles formed the most basal lineage among the mosquitoes.

01-262

THE ARMATURE IN THE GENITAL ATRIUM AS A MEANS OF DISTINGUISHING THE PHLEBOTOMINE SAND FLY SIBLING SPECIES *LUTZOMYIA CARMELINOI* RYAN ET AL. AND *L. LENTI* MANGABEIRA (DIPTERA: PSYCHODIDAE) OF BRAZIL

R. G. de Queiroz
Universidade Federal do Ceará, Fortaleza, Brazil

Recently, the armature of the membrane of the genital atrium has been successfully employed to distinguish females of close related species of phlebotomine sand flies of the Old World genus *Phlebotomus* (Killick-Kendrick et al., *Ann. Trop. Med. Parasitol.*, **88**, 433-437, 1994; Pesson et al., *Ann. Trop. Med. Parasitol.*, **88**, 539-542, 1994). In the present work, the genital area of several Neotropical sand fly species of the genus *Lutzomyia* was investigated to assess the usefulness of this taxonomic character to differentiate morphologically similar or indistinguishable species. Laboratory-reared (n = 20) and wild specimens (n = 10) of a same species from different places in Brazil, including type-localities, were examined by light microscopy. The shape, size and arrangement of spines of each species were compared to those of other species of the same subgenus or species group. To date, distinctive differences in the genital atrium have been recorded only between two species of the *migonei* group, namely *L. lenti* and *L. carmelinoi*. The genital membrane of the former does not appear to have spines apart from a few which can be seen in the edges of the membrane, whereas that of the latter has many long and conspicuous hair-like spines. These features were consistent and could be easily seen in all specimens examined. Therefore, *L. lenti* and *L. carmelinoi*, which have so far been distinguished with certainty only by differences in the length and shape of the genital filament tips of the males, can now be correctly identified even if only females are available. This character may be useful to distinguish other species of difficult identification. Financial support from WHO/TDR (M8/181/4/Q.21) and NIH (AI 16305-17).

01-264

NEWLY RECORDED SPECIES OF HORSE FLIES (DIPTERA: TABANIDAE) IN FAUNA OF CROATIA

Stjepan Krčmar
Department of Biology, Faculty of Education University in Osijek, L. Jägera 9. 31000 Osijek, Croatia

Faunistic collecting of horse flies and their research in the area of Croatia was carried out in the period from 1992 - 1995. The series of new species: *Haematopota bigoti* (GOBERT, 1881), *Hybomitra ucrainica* (OLSUFJEV, 1952), *Aylotus flavoguttatus* (SZILADY, 1915), *Hybomitra expollicata* (PANDELLE, 1883) and *Tabanus regularis* (JAENICKE, 1866) was recorded for Croatia.

Haematopota bigoti the first time was recorded on location in Petrijevci (CR 05) on the following dates: 02.06.1993 (2♀), 19.06.1993 (2♀), 22.06.1993 (4♀), 08.07.1993 (2♀), 09.07.1993 (9♀), 10.07.1993 (7♀), 29.07.1993 (1♀), 12.08.1993 (3♀), 13.08.1993 (1♀), 09.09.1993 (5♀), 25.09.1993 (2♀), 16.07.1994 (4♀), 23.07.1994 (2♀), 24.09.1994 (5♀), 26.05.1995 (2♀), 11.06.1995 (2♀), and Osijek (CR 24), 21.09.1993 (1♀), Staro Štefanje (XL 37), 08.06.1994 (2♀), Borovik (BR 83) 02.09.1994 (3♀), Borovik (BR 83), 12.09.1994 (3♀), Donja Glavina (XJ 71) 21.06.1995 (5♀), Prološko Blato (XJ 71), 22.06.1995 (5♀), Plesmo (XL 41), 30.06.1995 (1♀), Opuzen (YH 06), 26.07.1995 (1♀). All together there were collected 74 specimens.

Hybomitra ucrainica were caught on location in Petrijevci (CR 05) on the following dates: 27.05.1993 (2♀), 29.05.1993 (4♀), 31.05.1993 (1♀), 02.06.1993 (3♀), 10.07.1993 (1♀), 18.06.1994 (2♀), 02.07.1995 (1♀), and Opuzen (YH 06), 30.05.1995

(2♀). All together there were collected 16 specimens.

Specimens of species *Aylotus flavoguttatus* were collected on the location in Čokadinci (CR 04), 30.07.1994 (1♀), Donja Glavina (XJ 71), 21.06.1995 (1♀), Plesmo (XL 41), 30.06.1995 (1♀), Bokšić Lug (BR 75), 02.07.1994 (2♀). All together there were collected 5 specimens.

Hybomitra expollicata species was collected on the location in Opuzen (YH 06) and Modro Oko (YH 06) on May 30, 1995. Only two specimens were collected.

On a pasture beside the river of Cetina in Omiš (XJ 31) on July 26, 1995 two females of *Tabanus regularis* were collected. All in all there were caught 99 specimens, all of them female.

01-263

WEEVILS (COLEOPTERA: CURCULIONIDAE) FAUNA IN KRAGUJEVAC BASIN (SERBIA)

S. Pesic

Faculty of Science, po. box 60, 34000 Kragujevac, Yugoslavia

Kragujevac basin takes the central position in Serbia. The influences from all cardinal points are present, because there are not extremely high mountains around. This part of Europe has had interesting geological history. All this, including intensive anthropogenous activities in last century, results with interesting flora and fauna.

During investigations from 1987 to 1995, on 25 localities, the 355 species, from 80 genera and 22 subfamilies (including Rhynchitinae, Attelabinae and Apioninae) were collected and determined by author.

The basic conclusion is that human activities are not dramatic changed weevil's fauna in Kragujevac vicinity, but caused new quantitative relationships between and in weevils-settlements in different habitats. The very plastic weevil's fauna, with high adaptability, lives here. Will be interesting and necessary to follow it and in the future.

01-265

CONTRIBUTIONS TO TAXONOMY AND BIOLOGY OF MALAYSIAN SOLDIER FLIES (DIPTERA: STRATIOMYIDAE)

D. Kovac¹, R. Rozkošný²

¹ Forschungsinstitut Senckenberg, Frankfurt a. M., Germany

² Department of Zoology and Ecology, Faculty of Science, Masaryk University, Brno, Czech Republic

About 300 species of Stratiomyidae have been recorded from the Oriental Region. But there are many more species to be described and there is a considerable gap in our knowledge concerning the biology of the Oriental Stratiomyidae, the larval stages and the relationships between the genera.

During an ongoing study at the Ulu Gombak Field Studies Centre, near Kuala Lumpur, the senior author reared 11 species of soldier flies from phytosaprophagous larvae associated with decaying bamboo. Seven additional species were collected from other habitats in Gombak, e. g. deserted bee nests, or during field trips to the Temengor Forest Reserve (West Malaysia) and Poring Hot Springs (Sabah, East Malaysia).

We studied the biology of the soldier flies in some detail (e.g., habitat preference, territoriality) and described five new species: *Odontomyia latitibia* (Stratiomyinae), *Ptecticus brunetti*, *P. flavifemoratus*, *P. malayensis* and *P. proximus* (Sarginae). Descriptions of larvae and new biological data were published for *Camptopteromyia fractipennis* (Pachygasterinae), *Ptecticus longipennis* and *P. malayensis*. Further adult and larval descriptions are being prepared for 5 species of *Ptecticus* and several species from the subfamilies Hermetiinae and Pachygasterinae. The collected material enabled us to prepare identification keys for *Ptecticus* and other genera, helped to delimit more precisely some genera in both the larval and adult stage and markedly extended the present knowledge of the Malaysian Stratiomyidae fauna.

01-266

A TAXONOMIC SYNOPSIS OF THE BETHYLIDAE (HYMENOPTERA: CHRYSIDOIDEA) OF THE ORIENTAL REGION AND THE EASTERN PART OF THE PALAEARCTIC REGION

M. Terayama

Shion Junior College, Hitachi, Ibaraki, Japan

The present status of the classification of the Bethylidae of the Oriental region and the eastern part of the Palaearctic region is briefly reviewed.

Two hundred sixty-four species of 38 genera in 5 subfamilies are listed until 1993: 252 species in the Oriental region and 14 species in the eastern part of the Palaearctic region.

At genus level, 24 genera belonging to the subfamily Epyrinae, 5 genera to the Mesitiinae, 4 to the Pristocerinae, 3 to the Bethylinae, and 1 to the Galodoxinae are recognized. The Oriental region is richest in genus number comparing with other zoogeographical regions.

Kurian (1954) listed 152 species of the Asian Bethylidae. Almost forty years after, by the publication of the check list of Kurian, only 112 species had been added in this fauna. It is safely said that the Asian bethylid fauna has been left unstudied. Current taxonomic works try to revise Japanese Bethylidae. As a result, 72 species of 16 genera are recognized of which 63 species (88%) and 8 genera (50%) are newly recorded. The number of species of bethylid wasps in Asia are estimated more than 2,000, belonging to more than 40 genera of 5 subfamilies.

01-268

SYRPHIDS (DIPTERA, SYRPHIDAE) IN UZBEKISTAN

D.B.Daminova

Department of General and Experimental Entomology, the Institute of Zoology, Tashkent, Uzbekistan

In Uzbekistan, 130 syrphid species comprising 3 subfamilies, 12 tribes and 35 genera have been recorded. Fifty-five species have been first recorded for Uzbekistan. *Heringia senilis* Sack, *Mallota cimbiciformis* L. and *Xylota segnis* L. are first recorded for Central Asia. The most diverse is the fauna of the middle mountains (117 species or 81%). Of this number, 70 species are encountered only in this zone. In the foothills revealed are 55 species (43%); in tugai and deserts 30 species (25%) and 12 species (9%), respectively. In the cultivated landscape 50 species (38%) are recorded. Six biological groups have been distinguished, which are represented mostly by aphidophages (36%) and phytophages (25,4%), and three ecological groups, in which mesophylls constitute 86% of the total fauna. There are twelve zoogeographic groups. Eastern Mediterranean individuals prevail among the Palaearctic immigrants of the syrphids. This is especially notable for the tribe Syrphini. The species endemism constitutes 30,7%. Most endemics are in the genera *Eumeria*, *Merodon*, *Ceriana* and *Chrysotoxum*. Further studies of the mountain regions may increase the number of the syrphids up to 180-200 species.

01-267

ENTOMOFAUNA OF QATAR : ORHOPTERAN INSECT SPECIES

R.M. ABDU

Dept. of Zoology, Faculty of Science, University of Qatar, Doha, State of Qatar Arabian Gulf.

The peninsula of Qatar lies between 50°45'E to 51°40'E longitude and 24°30'N to 26°10'N Latitude, it occupies the Midway between shatt El-Arab and strait of Hormmuz. Systematics sampling of insects was commenced by the author from various biotopes of state of Qatar covering wadis, gardens, farms and plains. The collected insects comprises 23 species in 21 genera belonging to 4 families. Belonging these species: *Anacridium aegyptium* L. *Acrida pellucida* Klug. *Schistocerca gregaria* forsska°L., *Sphingonotus savignyi* Saussur, *Truxalis nasuta* L. *Liogryllus biomaculatus* de Geer, *Gryllotalpa africana*, *Conocephalus conocephalus* Linnaeus and other species.

01-269

THE PROTAPION SCHILSKY SPECIES (APIONIDAE, COLEOPTERA) FROM THE ROMANIAN FAUNA.

I.Pălăgeşiu

Department of Entomology, Banat's University of Agricultural Sciences, Timişoara, Romania.

Findings concerning the distribution of the Protapion Schilsky species in Romania are presented in this paper. We have mentioned the collecting place and date and also the host plants.

In Romanian fauna the Protapion Schilsky species are relatively well represented. On the basis of carried out investigations it presents the common, scarce and new species from Romania.

For the achievement of this study there have been examined the most important entomological collections from Romanian museums, there have been reviewed the references concerning the distribution of these species on the Romanian territory and there also have been used the author's investigations carried out between 1963-1995.

01-270

THE GRASSHOPPERS AND LOCUSTS OF EASTERN AND NORTH-EASTERN AFRICA

N.D.Jago
Natural Resources Institute, Central Avenue,
Chatham Maritime, KENT ME4 4TB England.

The acridid fauna of the region (Ethiopia, Eritrea, Somalia, Uganda, Kenya, Tanzania & Zanzibar) includes an estimated 745 species, of which 95 have been described as new since 1982 or are currently in press. At generic level, 28 taxa have been described as new during the same period out of a total of 246. Many more crypto-species and subspecies may await diagnosis, likely recognition being based on presence or absence of adult diapause and genetic compatability linked to seasonal occurrence. Centres of greatest acridid biodiversity can now be recognised within 17 biogeographical subregions. Those exhibiting volcanic activity in geologically recent times have low levels of species diversity and endemism. Ancient orogenic belts, such as those around the periphery of the Masai steppe, along coastal Kenya and Tanzania and at the foot of the Ruwenzori Mts. are rich in endemics. The subf. Gomphocerinae contains genera which extend from Africa to Saudi Arabia, Iran and India. This blurs the distinction between the African and Indian subregions.

01-272

COMMENTS ON CURRENT RESEARCH ON SHOOT FLY TAXONOMY AND BIOLOGY AND SUGGESTIONS FOR FUTURE RESEARCH (DIPTERA: CYCLORRHAPHA)

J.C. Deeming
Department of Zoology, National Museums & Galleries of Wales, Cardiff CF1 3NP, UK

Shoot flies of a diversity of families, especially Muscidae, Anthomyiidae, Chloropidae and Diopsidae, are injurious to cereal crops and pasture. Pests species occur wherever such crops are grown. Some species appear to be restricted to specific host plants, whereas others are polyphagous. Much traditional taxonomy based upon museum specimens remains to be done. This is legitimate, but has its limitations. It is by rearing from host plants that sexes of the same species can be definitely associated and the range of alternative host plants established. The taxonomy of immature stages must be taken into consideration to corroborate or disprove species concepts. Within the Chloropinae ovoviviparity has been found to be the developmental strategy in several genera, though to what advantage to the fly remains unknown. In *Atherigona* spp. (Muscidae) bacteria and other micro-organisms undoubtedly play an important part in rendering plant material edible. To identify such micro-organisms associated with individual pest species is a prerequisite to understanding their nutrition and might well prove useful in their control.

01-271

CUTICULAR HYDROCARBONS AND SPECIATION IN THE GENUS *GRYLLOTALPA* FROM ISRAEL AND ITALY

M.Broza^①, J.L.Natoh^②, and B.Baccetti^③
^① Dept. of Biology University of Haifa, Oranim, Tivon 36006, Israel
^②Dept. of Entomology & Nematology, University of Florida, Gainesville Fl. 32611 USA ^③ Dept. of Evolutionary Biology, University of Siena, 53100 Siena. Italy

The *Gryllotalpa gryllotalpa* L. group (Gryllotalpidae: Orthoptera) from Europe and the Eastern Mediterranean includes at least 12 sibling species. The different species have been characterized by different number of chromosomes; from 12 in Western and Central Europe up to 19 and 23 on the Eastern Mediterranean. Some of the species have been discriminated by the chromosome numbers only [*G. quindecim*, *G. sedecim*, *G. octodecim* (Baccetti & Capra)]. In the present study we found that the hydrocarbon fraction of the cuticle lipids provided reliable characters for species recognition in this group. Isolated populations of mole crickets with 2N=23 chromosomes (males) are known from two separate and distinct localities: along the shore of the Dead Sea in Israel and along the shore of a crater lake in the Pantellaria Island, south of Sicily, Italy. The latter population was described by Baccetti & Capra as *G. cossyrensis*. Morphologically the crickets are very similar but their hydrocarbon pattern shows that they are distinctly separate species. These two highly isolated and local populations present an impressive convergent response to harsh environmental conditions including hypersaline soil and high temperature along the Dead Sea and living under rocks at the bank of hot thermal water in the crater lake of Pantellaria.

Section 2

Biogeography and Biodiversity

02-002

RELATIONSHIPS BETWEEN MOLECULAR, HABITAT, AND BEHAVIORAL DIVERSITY USING APHIDS AS A PARADIGM

Don C. Peters

Department of Entomology, Oklahoma State University, Stillwater, OK USA

As the ability to sequence and manipulate DNA and related molecules and associated genetic information advances, the distinction between genetic diversity and species diversity becomes obliterated. Parthenogenetic aphids with the potential of annual sexual cycles provide unique models for the study of bio/genetic diversity. Genetic diversity of agricultural insect pests is viewed as a negative; born witness to by the over 500 species which have developed resistance to one or more insecticides.

A recent summary of insects overcoming plant resistant varieties or cultivars listed 9 of 14 as aphid species. Such genetically differentiated insect populations capable of feeding ^{on} genetically differentiated cultivars are often referred to as biotypes. We have accumulated 8 such biotypes of greenbugs in our laboratory. Additional differential crop entries would cause an exponential increase in the possible number of biotypes.

Determining the frequencies of greenbug biotypes in a region is important to the success of plant resistance programs. Using differentiating cultivars is laborious; therefore, we have attempted to use a variety of molecular methods which have proven to be effective in differentiating other insect populations for differentiating aphid biotypes. Our sampling and laboratory breeding results with greenbugs will be compared with results from other aphid programs.

02-001

MAINTENANCE AND GOVERNANCE OF INSECT BIODIVERSITY IN AGROECOSYSTEMS

J.A. Lockwood

Department of Plant, Soil, and Insect Sciences, University of Wyoming, Laramie, WY

A position from which Biodiversity can be understood and defended in principle and in practice is developed. First, although Biodiversity has intrinsic value, this is not sufficient to change human practices. If Biodiversity is to be preserved, it must be understood in terms of conditional values to human interests. Biodiversity is ultimately local, site-specific, and intimately tied to "Place". The concept of Place is an historically vital concept in Western culture which, although marginalized during the Industrial Revolution, is increasingly used in the context of literature, art, popular culture, and science. As human populations increase and we are no longer able to "exploit and move" in agriculture, an emerging understanding of Place appears to be have promise for culturally grounding preservation of Biodiversity. Ultimately, the maintenance and governance of insect Biodiversity is linked to the human condition and perspectives, and the emergent sense of Place may be key to the preservation of species and processes. Given the importance of insects in characterizing the fauna, flora (indirectly), and ecology -- these organisms not only critically define; but even become, "Place". As we come to recognize the essential element of insects in defining the Places which societies and communities value, it will become possible to maintain Biodiversity. Thus, entomologists must engage in research and teaching that provides a foundation for the cultural understanding of insects and their essential role in defining the Places we value.

02-003

INSECT BIODIVERSITY AND THE GEOLOGICAL RECORD: IMPLICATIONS FOR THE MODERN ERA

C.C. Labandeira

Department of Paleobiology, MRC-121, National Museum of Natural History, Smithsonian Institution, Washington, DC, USA 20560

Macroscopic taxic diversity on land is dominated by insects and their interacting partners, vascular plants. Understanding the origin, evolution, and maintenance of this diversity at geological time scales must include extensive examination of the fossil record of insects and especially their interactions with plants. Although compilations of fossil insect diversity have been derived by systematic studies, recent exploration of the paleoecology insect herbivores and their plant hosts have provided new and valuable data. Both approaches address three questions: Approximately when did recognizably modern terrestrial insect diversity originate? How has this diversity been maintained? Have increasing levels of plant defense occurred as a response to insect herbivore pressure?

Winged insects are not known until the Early Pennsylvanian, at 325 Ma. At that time 11 orders of insects were already established and by the Late Pennsylvanian (c. 300 Ma) detritivores, carnivores and, notably, herbivores were present in Euramerican coal-swamp communities that were characterized by considerable partitioning of live and dead food resources. There is strong evidence for a modern-aspect ecosystem of principally insects interacting with plants in intricate ways, including host-specific partitioning of particular plant tissues, and multiple strategies for extracting food, including boring, piercing-and-sucking, galling, external feeding, spore consumption, and probably leaf mining. *Psaronius* tree ferns and *Medullosa* seed ferns harbored the most diverse of these insect herbivore communities. Subsequent diversification of Mesozoic seed plants accelerated ecologic and taxic diversification of insects, and angiosperm dominance did not result in any major insect feeding novelty. The family-level fossil record indicates this diversification was propelled by increasing rates of origination coupled with minimal rates of extinction.

The myriad interactions among modern insects and plants originated as ancient associations in Pennsylvanian coal-swamp forests and in modern insect groups finely partitioning Mesozoic seed plant tissues. During this time, herbivory levels indicate that plant defenses escalated to respond to increasing herbivore pressure. Although modern-aspect insect diversity began around 300 Ma, recent anthropogenic disruption far exceeds that caused by abiotic disruptions of the geologic past.

LANDSCAPE MOSAICS AND INSECT DIVERSITY
M.J. Samways
Invertebrate Conservation Research Centre, Department of
Zoology and Entomology, University of Natal, Pietermaritzburg,
South Africa.

Landscape fragmentation has been a vast unplanned experiment, with insect populations across the world being forced into new geometrical patterns. Yet these patterns are not the same for all species in all areas. Many species do not even see, or respond to, the landscape as we see it. For others, the landscape is variegated rather than fragmented. And for yet others, it does not matter whether the land is trampled by game or by cattle. Then there are others that thrive in a new, exotic plantscape. Conversely, others are devastated by it. So, is there a general paradigm of how insect diversity responds to agricultural and urban fragmentation? This question will be explored here.

BIOGEOGRAPHY, BIOLOGICAL DIVERSITY, AND CONSERVATION OF INSECT FAUNAS AND THEIR HABITATS BY TRADITIONAL PEOPLES IN THE NEOTROPICS

Keith S. Brown Jr.

Departamento de Zoologia, Instituto de Biologia, Universidade Estadual de Campinas, Campinas, São Paulo, Brazil

The distribution patterns of butterfly **endemism** at the species and subspecies levels, **diversity** at genetic, species, and community levels, and **rarity** (concentrations of little-known, scarce, or threatened taxa) were analyzed throughout the Neotropics (over 2000 data-points). Regions of maximum values for these important system qualities do not normally overlap, suggesting that they arise by different mechanisms acting over different time-scales. Ancient vicariance through mountain uplift and water barriers correlates with species endemism, while Pleistocene paleoecology agrees with lower-level differentiation. Unpredictable disturbance produces and maintains high beta-diversity, while complex chance processes in scattered small sites allow erratic survival of primitive and rare species in irreplaceable "paleoenvironments".

These non-coincident distribution patterns make the conservation of all these factors very difficult, especially if only in a predetermined system of official conservation units. In such limited areas, the maintenance of natural system processes such as microevolution, colonization, predator and parasite cycles, diversification, and high beta-diversity is problematic. Their management requires the input of much energy, usually resulting in the irreversible simplification and destructuring of the system and of insect communities.

Studies of low-density "rustic" human communities resident in the Neotropics show that they often maintain or even enhance system diversification processes on their traditional lands, through mild disturbance associated with empirically sustainable natural resource use patterns, attained over long periods of selection on their cultural practices and interactions. In contrast, higher-density, market-directed or exogenous societies rarely demonstrate sustainable use of their natural resources, and often destructure the systems to the point where reduction in diversity becomes irreversible. Thus, true conservation can often be attained by protection of such traditional societies and their resource-use patterns, across the landscape and at all scales of time and space.

02-010

ON THE BIOGEOGRAPHICAL ANDEAN SUBREGION

J. J. Morrone and J. V. Crisci

Laboratorio de Sistemática y Biología Evolutiva (LASBE), Museo de La Plata, Paseo del Bosque, 1900 La Plata, Argentina

The Andean subregion is defined within a biogeographical system of the world, where three biogeographical subregions are recognized (Holarctic, Holotropical, and Austral). South America is divided in two subregions: Andean and Neotropical; the former belongs to the Austral region, whereas the latter belongs to the Neotropical region.

Based on distributional patterns of more than 200 genera, species groups, and species of terrestrial and freshwater Arachnida (Araneae, Opiliones, Pseudoscorpionida, Scorpiones, and Solifugae), Crustacea (Decapoda), and Hexapoda (Coleoptera, Diptera, Homoptera, Hymenoptera, Lepidoptera, Odonata, and Orthoptera), the following five provinces are recognized within the Andean subregion:

- (1) Subantarctic: Austral Andes, from 37° south latitude to Cabo de Hornos, including the archipelago of southern Chile and Argentina.
- (2) Central Chilean: Central Chile between 32° and 37° south latitude.
- (3) Puna: Highlands from southern and central Peru, western Bolivia, northwestern Argentina, and northern Chile, basically over 3000 m altitude.
- (4) Patagonian: Semidesert west of the Austral Andes to the Atlantic coast in Argentina, extending in some places to Chile.
- (5) Paramo: Northern Andes from northern Venezuela, Colombia, and Ecuador, over 3000 m altitude.

The Central Chilean and Subantarctic provinces represent the richest areas in endemic species and taxa with phylogenetic value, thus their high value for biodiversity conservation.

02-009

BIOGEOGRAPHY OF THE MEXICAN TRANSITION ZONE: HYBRID AREAS AND GENERAL AREA CLADOGRAMS

C.J. Marshall, J.K. Liebherr

Department of Entomology, Cornell University, Ithaca, NY, USA

The Mexican Transition Zone contains a biota with diverse historical origins. A diverse endemic biota, existing in the region since the breakup of Pangaea, is complemented by more recent colonization from the north via the Sierra Madre Occidental-Rocky Mountain axis starting in the Oligocene, and from South America via the Panamanian isthmus since the Plio-Pleistocene. Given such a diverse array of biogeographic histories, the search for a general pattern of area relationships as proposed in cladistic biogeography is called into question. Nonetheless, areas of endemism can be defined by mountain system, with many taxa restricted to limited expanses of montane habitat. Using cladistic biogeographic methods, we analyze biogeographic patterns in a diversity of these montane taxa, focusing on Passalidae and Carabidae (Coleoptera), but also including other insects, fish, lizards and plants. Areas of endemism include the Sierra Madre Oriental, S.M. Occidental, southern S.M. Occidental, S.M. del Sur, Sierra Transvolcanica, Chiapas-Guatemala Highlands, Talamancan Cordillera, Arizona Mountains, and Sonoran Desert. We compare estimates of patterns based on members sharing coincident biogeographic tracks to those hypothesized based on data combined from all groups representing all histories. The former analysis may provide better understanding of taxa sharing a similar history, but the latter can serve as a useful tool for identification of areas requiring preservation. By all methods and taking into account the current biosphere network, the region at most risk for massive loss of biodiversity is the Sierra Madre del Sur.

02-011

BIOGEOGRAPHICAL PROCESSES AND SPECIES RICHNESS IN THE NEOTROPICAL INSECT FAUNA

M. Zunino, M.S. Colomba

Istituto di Zoologia, Università di Palermo, Italy

Faunal specific richness of a given biogeographical unit is currently ascribed to two classes of different causes, i.e. environmental heterogeneity and ecological history. Biogeographical relationships history of the implied area is usually invoked as a causal factor contributing to the taxonomical heterogeneity degree of a given biota and - *a fortiori* - of its entomological component. However, analyzing how homologous groups of Insects are represented in different tropical areas, we are allowed to suppose that these relationships could play a relevant role in determining specific richness too. Such hypothesis is discussed by means of the analysis of some Insect groups showing disjunct distribution in Eastern Asia and Tropical America and of possible effects of climatic belts shifting during past geological epochs.

The main basic concepts advanced are : i) specific distribution area, which is not regarded just as a merely spatial attribute of the species itself, but as the portion of geographic space in which the species is present and interacts in a non occasional way with the ecosystem. Consequently, it has ontological properties; and ii) dynamic vicariance, which is thought as a process implying range splitting rather than barriers' arising in a previously occupied area. In this process entire biota, not single species more or less isolated from their synecological context, are affected.

Dynamic vicariance, acting on a highly anisotropic scenario, is capable of provoking not only qualitative changes in the extant entomofaunas composition, but also the increase of their specific richness.

02-012

COLEOPTERA PASSALIDAE OF THE AMERICAS
P. Reyes-Castillo, J.C. Schuster¹
Instituto de Ecología, Xalapa, Veracruz, México - 1
Universidad del Valle de Guatemala, Guatemala, Guatemala.

Distribution of Passalidae species in countries of North America, Mexican Transitional Zone, South of Central America, South America and the Antilles was analyzed. Latitudinal and altitudinal limits related to species distribution in the American Continent were determined. Total species number was assessed for each country, and their distributional extent and degree of endemism in relation to vegetation type and microhabitat were identified.

General and particular dispersal patterns at the tribe, genera and species levels are discussed considering group phylogeny and continental geological history. High species richness and high endemism areas were ascertained, as well as those areas needing further exploration.

02-014

BIODIVERSITY AND DISTRIBUTION OF THE NEOTROPICAL GENUS PSEUDOCHEILA GUERIN, 1839 (COLEOPTERA: CICINDELIDAE).
F.Cassola
WWF-Italy, Rome, Italy.

The genus Pseudocheila was created by Guérin-Méneville for the species Cicindela bipustulata Latreille, 1881, based on material collected by Alexander von Humboldt during his famous expedition to the Nueva Grenada. Seven additional taxa were subsequently described by other authors (Chaudoir, Bates, Dokhtouroff and W.Horn), all of which were later synonymized by W.Horn into bipustulata. Thus the genus Pseudocheila was thought so far to include a single species only (bipustulata) or two species at most (bipustulata and tarsalis Bates, 1869). Surprisingly, a careful revision, based on the study of type and older specimens as well as of large recent material from several sources, made it clear that Pseudocheila, far from being a monotypic genus, comprises no less than 20 different full species (12 of which are being described as new to science), ranging in mountainous areas from Costa Rica south to the Andean slopes of Bolivia. The distribution and the possible origins and mutual relationships of such species are presented and discussed.

02-013

NEW WORLD CARABIDAE (COLEOPTERA) AND FAUNAL CONNECTIONS OF MIDDLE AMERICA
George E. Ball
Department of Biological Sciences, University of Alberta, Edmonton, Alberta, Canada

The native (introduced taxa excluded) carabid fauna of Middle America (including the West Indies) includes the following geographical components: an older one (late Mesozoic- early Tertiary) of indigeneous genera, species groups, and phylogenetically isolated species; and three younger (late Tertiary-Quaternary) elements , regarded as adventive-immigrant, and classified according to source area: South America; North America north of México; and the Old World (Africa, or the warmer parts of the Palaearctic Region). Overall, the immigrant element is predominant, particularly the South American component , as shown by numbers of genera represented in Middle America. Thus, carabid movement in the New World seems to have been principally in a south-north direction, rather than the reverse. This is reflected also in the putatively older, precinctive elements: most of them exhibit southern connections, as well.

02-015

TAXONOMIC AND ECOLOGICAL COMPOSITION OF THE TREEHOPPER (HOMOPTERA: MEMBRACIDAE) COMMUNITIES OF A LOWLAND NEOTROPICAL RAINFOREST
S.H. McKamey, Danish Centre for Tropical Biodiversity and Department of Entomology, Zoologisk Museum, Copenhagen, Denmark
The treehoppers collected by insecticidal fogging of tree canopies in five neighboring forests at Tambopata, Peru, were examined in terms of richness and abundance of species and guilds, which were defined by the degree of aggregation and ant-mutualism. From sampling above 4725m² of forest floor, Tambopata was estimated to have approximately the same treehopper richness (200) as the entire Nearctic. Species complementarity (distinctness) among the five Tambopata forest types was high, varying from 79% to 95%, but this was partly explained by small sample sizes. The Terre Firme forest had the second smallest sample size but had the most species. Guild composition varied significantly among forest types (p < 0.001). However, the incidence of mutualistic treehopper species did not track the incidence of their mutualistic ant 'partners'. The fogged specimens from Tambopata (TA) were compared to the results from classical collecting techniques in lowland rainforest sites of Brazil (BR, 660 km distant), Ecuador (EC, 1550 km distant) and Colombia (1900 km distant). Species complementarity was relatively low: 0.81 TA-BR (≈ 30% of TA species in BR samples); 0.91 TA-EC (10% of TA species in EC samples). Thus, the pooled Tambopata sample was less distinct from the analyzed Brazil sample, 660 km distant, than were most of the forest types within Tambopata. Although the distant samples were obtained by different methods, supraspecific differences among all of them seemed mostly attributable only to the vertical stratification used in each case. An explicit method is proposed to wed phylogeny and ecology in community diversity studies. Convex guilds are historically tied, ecologically similar groups of species that, consequently, may respond similarly to forces affecting patterns of distribution and abundance. This concept thus has relevance to community diversity studies, which describe and interpret these patterns. Examining the distribution and abundance of treehopper convex guilds facilitated biological interpretation of community guild patterns and suggested that Tambopata treehopper community differences were partly due to phylogenetic effects.

02-016

AN APPROACH TO THE KNOWLEDGE OF THE INSECT FAUNA OF MONTE: A PERSPECTIVE.

S. Roig-Juñent, S. Claver, G. Debandi, G. Flores, and A. Marvaldi

Instituto Argentino de Investigaciones de Zonas Áridas (IADIZA), Mendoza, Argentina.

Argentina possesses an extended area occupied by arid lands, which could be grouped in three main arid biomes: Patagonia, Puna, and Monte. Patagonia and Puna are cold steppe, the first of low altitude in the south, and the second in high mountains in the north. The Monte is a warm scrub desert, extended between the Puna and Patagonia, and, floristically, it can be defined as the *Larrea* distribution area, including other Zygophyllaceae as *Bulnesia* and *Plectocarpa*. The Monte is of a particular biogeographical interest because it extends from the neotropical to the antarctic regions. Patagonia and Puna are evolutionarily related, while Monte faunal and floral elements are most closely related to those of Pampa and Chaco. Most of the studies developed in the Monte area deals with vertebrates. Works on Monte insects are increasing, mainly dealing with a particular taxon or a small area, and mostly referred to the northern area of Monte.

The principal objective of this paper is to develop a program in order to increase the knowledge of the Monte insect fauna. It comprises three main points: a) **Biodiversity**: A common idea is that the Monte is a poor Chaco, but nobody has done, particularly for insects, a comparison of species between these two areas. In this paper, a preliminary list of species from Monte is presented and compared with the Chaco area concerning four families of Insects: Formicidae, Chrysomelidae, Curculionidae, and Tenebrionidae. Protected areas of Monte are basically based on landscape, protection of forest or certain species. However, it does not exist a preliminary plan or inventory of insect fauna to create a protected area for insects. b) **Biogeography**: Classically, endemic species or genera defined a natural area. In the Monte no analysis of endemism was ever developed. A preliminary study is developed, plotting on a map the geographical range of species, and then analyzing this information. The analysis of endemism together with phylogenetic studies of several groups will provide the basis to develop the history of the area and its relationships with other areas. c) **Ecology**: Three kind of ecological programs are being developed in the laboratory: a) a soil fauna analysis in different protected areas examining patterns of temporal distribution; b) an exhaustive study of insects associated to *Larrea*; and c) analyses of daily and monthly patterns of activity of leaf-cutting ants. These studies provide information about ecological ranges, insect-plant relationships, species as indicators of environmental changes, and comparison between disturbed and natural areas.

02-017

HABITAT STRUCTURE AND ARTHROPOD DIVERSITY IN ARGENTINE SEMI-ARID CHACO

S.M. Gardner, M.R. Cabido¹, G.R. Valladares²

Centre for Extra-Mural Studies, Birkbeck College, London, UK - 1 IMBIV, Universidad Nacional de Córdoba - CONICET, Córdoba, Argentina - 2 CIEC, Universidad Nacional de Córdoba, Córdoba, Argentina

In this paper we examine the extent to which changes in habitat structure, arising from logging and grazing, influence the diversity of ground-dwelling arthropods in semi-arid Chaco forest. The structure of four forest habitats is assessed from quantitative measurements of plant species diversity, spatial distribution and architectural complexity. Arthropod diversity is assessed according to the abundance of different families and functional groups (e.g. predators, detritivores, herbivores). The data indicate that the physical structure of the habitat, architectural complexity and height profile, exerts the strongest influence on the arthropod community; family diversity was significantly smaller in the structurally simpler habitats. Such habitats also exhibited a significant change in the functional composition of the arthropod community.

02-018

BEE AND PLANT DIVERSITY IN THE SOUTHERN REGION OF THE ATACAMA DESERT OF CHILE

L. Ruz, H. Monzón, R. Villaseñor*, S. Rodríguez

Instituto de Biología, Departamento de Entomología, Universidad Católica de Valparaíso, Chile - *Facultad de Ciencias, Universidad de Playa Ancha, Valparaíso, Chile.

In the arid site South of Copiapó (lat 27° 18' S, long. 70° 25' O), during the blooming season of 1989 and 1991 were found:

1) A desert scrub corresponding to only one community with 6 main species, being *Nolana rostrata* (Nolanaceae) notoriously predominant, followed by *Argylia radiata* (Bignoniaceae) and other less abundant scrub and herbaceous species. 2) The associated bees to this vegetational community belong to 27 species and 6 families. 3) The plant species most preferred by bees, because of their highest diversity, was *Encelia oblongifolia* (Compositae) in 1989, and *Argylia radiata* in 1991. 4) During the latter year a higher diversity and abundance of bees were found, probably due to more favorable climatic conditions because of greater precipitation during winter. 5) The main bee species visiting *Argylia* were: *Leiproctus atacama* (27,42%), *Diadasia nemaglosa* (19,35%) and *L. herrerae* (11,29%). 6) *Encelia* was mainly preferred by: *Centris chilensis* (20,37%), *Megachile saulcyi* (18,52%) and *Mesonychium wagencknechti* (16,67%). Specific pollinators should be expected to be important in habitats like deserts, where their food resources, which they depend upon, are only available for short periods. Among the oligolectic bee species, *Diadasia nemaglosa* was found to be highly specialized on *Argylia*.

02-019

BIODIVERSITY OF THE ANTS (HYMENOPTERA: FORMICIDAE) OF THE VENEZUELAN ANDES.

P. J. Salinas.

Universidad de Los Andes. Mérida. Venezuela.

The Venezuelan Andes have about 250000 km² or near one quarter of the total country land. The altitudinal range vary from 0 m to 5007 m above sea level. There are 15 life zones, from xerophytic areas to nival zones, rain and cloud forests. These conditions favour a high biodiversity both in richness and endemism, especially shown by the ants. There are species from the Caribbean, the Amazonian and the savannahs areas, as well as the typical Andean and Cis-Andean species. The ants in the author collection, other collections and references are catalogued. Up to date there are catalogued around 60 genera, about 120 species determined and more than 120 species to be determined, some genera (*Camponotus*, *Pheidole*, *Solenopsis*, etc.) will give many species. The Ponerinae have 14 genera with 29 species determined and more than 20 to be determined. The Myrmicinae have 28 genera with 70 species determined and more than 40 to be determined. The Pseudomyrmecinae have one genus and more than 15 species to be determined. The Ecitoninae have 5 genera with 19 species determined. The Formicinae have 5 genera with more than 30 species to be determined. The Dolichoderinae have 6 genera with 21 species determined and more than 10 to be determined. Information is given on their geographical distribution in the Neotropical region and in Venezuela. Localities in the Andes are given with the number of samples for each locality. Ecological data such as altitudinal range, habitat, microhabitat, life zones, as well as ethological data such as the occurrence are given. Biogeographical maps are presented.

02-020

BIODIVERSITY OF THE ANTS (HYMENOPTERA: FORMICIDAE) OF TRINIDAD AND TOBAGO. CATALOGUE AND DISTRIBUTION.

P. J. Salinas. *Universidad de Los Andes. Mérida. Venezuela.*

A Catalogue of the ants of Trinidad and Tobago is given, including species in the author's collection as well as other cited in the literature. There are 7 subfamilies with 66 genera and a total of 238 species determined. The Ponerinae have 16 genera with 37 species. The Cerapachyinae have 1 genus with 2 species. The Myrmicinae have 34 genera with 100 species. The Ecitoninae have 3 genera with 14 species. The Pseudomyrmecinae have 1 genus with 18 species. The Formicinae have 5 species with 35 species. The Dolichoderinae have 6 genera with 22 species. The genera with more species are: *Camponotus* (21 species), *Pseudomyrmex* (18 species), *Azteca* (12 species), *Pheidole* (11 species), *Strumigenys* (11 species) and *Trachymyrmex* (10 species). Bibliographic and ecological information on each species is given, such as references to original description, distribution in the Neotropical Region, and in Trinidad and Tobago. For each part of the country, the localities and records number are included. Also ecological data such as altitudinal range, habitat, microhabitat, life zones, as well as other ethological data such as occurrence. Maps of Trinidad and Tobago are given with the localities where the different species have been collected or recorded by other authors. List are given of all the ant species recorded in Trinidad and Tobago. A list of the collection localities is given, including the geographic coordinates and the altitudes of each place.

02-022

DISPERSAL OR VICARIANCE? HISTORICAL BIOGEOGRAPHY OF MARINE WATER STRIDERS (HETEROPTERA, GERROMORPHA) IN THE INDO-PACIFIC

N. Møller Andersen
Zoological Museum, University of Copenhagen, Denmark

More than 120 species of marine water striders (Hemiptera, Gerromorpha), representing three families and ten genera, are distributed throughout the Indo-Pacific region. They live in marine habitats such as mangroves, intertidal coral reef flats, and the sea surface near coral and rocky coasts. Five species of sea skaters, *Halobates* (Gerridae), have colonized the surface of the open ocean. Adult marine water striders are wingless but may disperse along coasts, chains of islands, and possibly across wider stretches of open sea. Although some species of coral bugs, *Halovelgia* (Veliidae), and *Halobates* are widespread, most species of marine water striders have rather restricted distributions. Based upon distributional data for marine water striders, a number of areas of endemism can be delimited within the Indo-Pacific region. Applying the methods of cladistic biogeography, the observed patterns of distribution are sought explained using both dispersal and vicariance hypotheses. The historical biogeography of marine water striders does not support the traditional division of the Indo-Pacific into the Ethiopian, Oriental, and Australian regions. The distributional patterns are more compatible with a set of hierarchical relationships between more restricted areas of endemism.

02-021

GEOLOGICAL HISTORY OF SE ASIA DURING THE LAST 50 MILLION YEARS

Robert Hall
SE Asia Research Group, Department of Geology, Royal Holloway University of London, EGHAM, Surrey TW20 0EX, U.K. (robert.hall@gl.rhnc.ac.uk)

This talk will attempt to describe the geological development of SE Asia and surrounding regions during Cenozoic time. This region is currently very active and since even present-day motions of plates and smaller crustal fragments are not fully understood it should not be surprising that making tectonic reconstructions becomes more difficult as the age of the reconstruction becomes greater. However, the present movements of major plates, such as the Pacific and India-Australia, are well known in relation to Eurasia, and these provide limits. Therefore by working back from the present-day we can make reconstructions, and the resulting interpretations offer a means of identifying important regional events and highlighting key problems. An animated plate tectonic reconstruction of SE Asia for the period 0-50 Ma will be presented to illustrate this approach (available free for a PC or Mac from <http://glsun2.gl.rhnc.ac.uk/seasia/welcome.html>). In this model, the major Cenozoic event in the region was collision of the Australian continent with a Philippine Sea plate island arc at ~25 Ma (end Oligocene) which resulted in major changes in the configuration and character of plate boundaries, and caused effects which propagated westwards through the region. This collision initiated major strike-slip faulting in northern New Guinea and led to the progressive arrival of Australian microcontinental fragments in Sulawesi, providing possible pathways for migration of faunas and floras between Asia and Australia, but also creating new barriers to dispersal. This new model will be discussed and compared to other geological models for the region, for example, those invoking terrane accretion. The animation offers a visual tool for exploring the consequences and validity of alternative interpretations and may be of some help to biogeographers. It is important to appreciate that the model shows the movement of plates and plate fragments which do not necessarily correspond to areas of land and sea. The geological record is a marine record; former land areas and periods of emergence are recorded by negative evidence, and even when there is a rock record it is often difficult to date. Nonetheless, an attempt will be made to indicate the likely distribution of land and sea although at present much of the information required to do this is not easily accessible or not available. Determining the palaeogeography of the region is a major task for the future. Completing this task, and testing the geological models, are problems to be solved for which evidence from all fields of biogeography is vital.

02-023

ASSEMBLING NEW GUINEA - 40 MILLION YEARS OF ISLAND ARC ACCRETION AS INDICATED BY THE DISTRIBUTION OF AQUATIC HETEROPTERA

Dan A. Polhemus, John. T. Polhemus¹,
Smithsonian Institution, Washington, D. C., USA
- ¹. Colorado Entomological Museum, Englewood, Colorado, USA

The island of New Guinea consists of the northern margin of the Australian continental craton that has collided over the past 40 million years with a series of migrating island arcs. Each of these arcs has had a separate tectonic history and carried a correspondingly different biota. Recent faunal surveys and phylogenetic analyses, coupled with evolving tectonic knowledge, have now allowed us to identify elements within the New Guinea aquatic Heteroptera biota that appear to be correlated with particular accreted arc systems. In particular, it appears that many Asian-derived groups arrived via a Papuan Arc in the Eocene, while many other distinctively Melanesian groups evolved on an initially isolated Solomons Arc that appeared in the Oligocene. The understanding of this interrelated tectonic and biotic history has in turn permitted a better comprehension of the complex patterns of faunal fusion and disjunction currently present within the Melanesian region.

02-024

BIOGEOGRAPHIC PATTERNS IN INDO-PACIFIC MIRIDAE (HETEROPTERA)

G. M. Stonedahl

International Institute of Entomology, London, UK
The methods of cladistic biogeography are applied to selected monophyletic groups of Miridae (Heteroptera) in south-east Asia and the tropical Pacific. An overall scheme of area inter-relationships is derived and compared with the results of other studies of aquatic and terrestrial invertebrates. Congruent patterns of distribution in these groups and the recognition of discrete areas of endemism lend support to geological hypotheses concerning the composite origin of the Philippines, Sulawesi, New Guinea, and other complex land masses in the Indo-Pacific region.

02-026

BIODIVERSITY AND BIOGEOGRAPHY OF THE TIGER BEETLES (COLEOPTERA: CICINDELIDAE) OF THE PHILIPPINE ISLANDS.

F. Cassola, R.D. Ward¹

WWF-Italy, Rome, Italy. ¹The Carnegie Museum of Natural History, Pittsburgh, PA USA.

The tiger beetle fauna of the Philippine Islands is reviewed and a total amount of 134 different species is recognized (17 of which are still in need to be described). The great majority of these species (i.e. 114 species, the 85 per cent of the whole fauna) is strictly endemic to the Archipelago, and moreover 6 non-endemic species occur here with endemic subspecies. Thus the Philippines appear to be the sixth richest country in the world (after Indonesia, India, Brazil, Madagascar and Zaire) as for the number of inhabiting species, the fifth richest one (after New Zealand, Madagascar, New Caledonia and Australia) as for the ratio of endemic species, but definitely the second richest country as for the number of endemics (just after Madagascar). In a way, it has to be expected that further specialized research will significantly increase such figures in the future, when more islands, other than Luzon, will be intensively explored. On the other hand, however, the ecological devastation that has now befallen most of these islands is likely to rapidly wipe out unknown forest faunal treasures.

The possible origin of the Philippine tiger beetles and their relationships to Sulawesi, Maluku, Borneo and the Asian mainland are also discussed in a broader biogeographical context.

02-027

BIOGEOGRAPHY OF THE BUTTERFLIES OF SULAWESI
R. De Jong, R-I Vane-Wright (London-United Kingdom)

ABSTRACT NOT RECEIVED

02-028

BIOGEOGRAPHY OF SULAWESI BASED ON THE INSECT FAUNA OF LOTIC HABITATS, WITH SPECIAL REFERENCE TO DRAGONFLIES (ODONATA)

J. van Tol
National Museum of Natural History, Leiden, The Netherlands

The fauna of Sulawesi is characterized by a high percentage of island endemics. The fact that various speciose groups of Borneo do not occur in Sulawesi (e.g. the family Platynemididae of the Odonata) also indicates to a long period of isolation. Groups of closely related species confined to Sulawesi frequently have small distributional ranges, defining areas of endemism. Island endemism and small distributional ranges within Sulawesi provide the tools for two levels of biogeographical studies. First, a reconstruction of the origin of the Sulawesi fauna, and second, a reconstruction of the relationships of the respective areas of endemism within Sulawesi.

Widespread species occurring in Sulawesi are predominantly Oriental. Most island endemics have their presumed sister groups west of Sulawesi, although in some taxa the relationship between the Sulawesi and Philippine fauna is very close. The species of Oriental genera or species groups distributed from the mainland of Southeast Asia to the Papuan region frequently show a sister group relationship between the Sulawesi taxa and those of the area east of Sulawesi.

Long isolation and a turbulent geological history have obviously provided the opportunities for radiation in those groups that reached Sulawesi, e.g. the damselfly families Chlorocyphidae and Platystictidae. Based on phylogenetic relationships and distributions of the (micro)species involved, taxon-area cladograms will be presented. Relationships between areas of endemism based on lotic fauna largely coincide with reconstructions of the island's history based on geological data.

02-030

NOTES ON THE BIODIVERSITY AND BIOGEOGRAPHY OF XANTHOLININI FROM SOUTH-EAST ASIA: AN EXAMPLE OF A GROUP IN EVOLUTION (COLEOPTERA, STAPHYLINIDAE)

A. Bordon
Museo Zoologico de 'La Specola', Sezione del Museo di Storia Naturale dell'Università di Firenze, Florence, Italy

A revision of south-east Asian Xantholinini (Bordon, in preparation) has revealed the exceptional richness of this tribe of Staphylinidae in one of the largest but least studied regions of the world. Until now about 400 species (70% new) belonging to 39 genera (20 new) have been identified; some are pantropical and a few (in contrast to what was believed) are palaearctic (on the western and eastern boundaries); all the others are typical of south-east Asia and/or of the austral region. The genera with the most species are correlated on the one hand to the great biodiversity of the rain forest with many species living under the cortex of trees or in rotting wood and on the other by the Himalayan zone with humicolous, brachypterous, subapterous and microphthalmic species. This vast territory with its multiple environments is characterised by a great biodiversity, as revealed by the abundance of species and scarce number of specimens, by their diversification and specialisation, and by an evolutive convergence less frequent than what is known in other Staphylinidae. The morphological study shows an extraordinary variety in several structures. The sixth visible urite and male genital segment (sometimes with soldered pleura) can be normal, with the known modifications, or extraordinarily metamorphosed; the basal bulb has lateral lobes which can be normally developed, modified, exceptionally complex, atrophied, or absent; the internal sac can be simple, without any evident amature, with tiny sclerotized spines, or with enormous structures which can extend outside the abdomen. Such variety is the consequence not only of the diverse environments but also of an ongoing and complex evolutive process, about which little is known and much has yet to be learned, markedly characterising a tribe which should be provisionally isolated within the Staphylininae but whose taxonomic position should be reviewed in relation to the other tribes to which it is usually linked.

02-029

THE DISTRIBUTION OF APSILOCHOREMA ULMER, 1907 - BIOGEOGRAPHIC EVIDENCE FOR THE MESOZOIC ACCRETION OF A GONDWANIAN MICROCONTINENT TO LAURASIA (TRICHOPTERA: HYDROBIOSIDAE)

W. Mey

Museum für Naturkunde, Humboldt-Universität
Berlin

The genus *Apsilochorema* ULM. contains 42 nominal species. They are distributed over a wide range in continental South Asia, on the Sunda Islands, on the Outer Melanesian Arc and in Australia. The family is one of the most ancestral groups of extant Trichoptera. *Apsilochorema* is the only representative of the family occurring in the Northern Hemisphere. The evidence for a mesozoic immigration is based on the:

- fossil record of the family in Asia from cretaceous amber,
- ancestry of the South Asian species,
- sistergroup relationships on generic level,
- ecological competition with the Holarctic Rhyacophilidae.

02-031

THE IMPACT OF FOREST PLANTATION DEVELOPMENT ON MOTH DIVERSITY IN MALAYSIA.

J. Intachat¹, V.K. Chey², J.D. Holloway³, M.R. Speight⁴
Forest Research Institute Malaysia, 52109 Kuala Lumpur, Malaysia -1 Forest Research Center, P.O. Box 1407, 90008 Sabah, Malaysia -2 International Institute of Entomology, 56 Queen's Gate, London, SW7 5JR, U.K. -3 Department of Zoology, South Parks Road, Oxford University, OX1 3PS, U.K. -4

Tropical forests that are rich in biodiversity and timber resources have been logged indiscriminately in the past. Logging pressure on natural forest can be reduced with the creation of forest plantations. The impact on the geometrid moth diversity resulting from the creation of two different types of plantations, indigenous and fast-growing exotic, were discussed and compared with an advanced regenerating natural forest. Among the four forest plantations that were assessed, the indigenous plantation was found to support a higher geometrid moth diversity as indicated by Williams alpha diversity index. Second highest in geometrid diversity was the fast-growing exotic plantation planted with *Gmelina arborea* Roxb., followed by *Paraserianthes falcataria* (L) I. Nielson and *Acacia mangium* Willd. The implications of the creation of forest plantations were also discussed in the context of biodiversity and conservation.

02-032

GEOGRAPHIC HISTORY OF THE TROGIDAE (COLEOPTERA: SCARABAEOIDEA)

C.H. Scholtz

Department of Zoology & Entomology, University of Pretoria, Pretoria, South Africa

The small, cosmopolitan family Trogidae consists of three genera, *Trox* F., *Omorgus* Erichson and *Polynoncus* Burmeister and about 300 species. *Trox* is restricted to the Holarctic (subgenus *Trox*) and Afrotropical (subgenus *Phoberus* MacLeay) regions; *Polynoncus* occurs only in South America; *Omorgus*, with three subgenera, occurs in the Oriental and Afrotropical regions (*Afromorgus* Scholtz), southern Nearctic, Neotropical and Australasian regions (*Omorgus s. str.*), and South America (the monobasic *Haroldomorgus* Scholtz). Relationships between and within genera have been cladistically inferred by analysis of adult and larval characters.

Cladistic and biogeographic evidence points to a Laurasian origin for *Trox* and a Gondwanan origin for *Omorgus*. The less derived subgenus *Trox* is restricted to the Holarctic while the more derived *Phoberus* has clearly invaded and evolved in Africa, after the break-up of Gondwanaland. The most derived *Afromorgus* species are restricted to the African-Oriental regions while those of subgenus *Omorgus* are widespread in southern North America, South America and Australia, pointing to a typical Eocene radiation between South America and Australia and a much more recent invasion of North America from South America. *Polynoncus* and *Omorgus* (*Haroldomorgus*) are South American endemics.

02-034

CLIMATO-ECOLOGICAL ZONATION OF GONDWANALAND

S.Endrödy-Younga. Transvaal Museum, Pretoria, South Africa

It has become evident that extant organisms often indicate past land connections between parts of the South Continents. Such distribution patterns are termed Gondwana-type. The frequency and level of phylogenetic relations between separated taxa already helped to determine the sequence of continental break-up. Ecological data provided by those taxa are, however, seldom evaluated.

The size and position of Gondwanaland implies the existence of climato-ecological zonation of the mega-continent. Such zones must have existed between the extremes of oceanic and continental, as well as between cool-temperate and tropical zones.

Depending on the level of conservatism to their native habitats, a range of taxa appear to inhabit the same climato-ecological areas on the separated continents even at present. Examples will be presented from different families of Coleoptera that are indicators of climato-ecological zonation of Gondwanaland. The continuity of former will be shown between South America (Antarctis) New Zealand and Australia, and between Africa and its sister continents and land-masses.

02-033

THE BIOGEOGRAPHY OF WEEVILS ON SOUTHERN OCEAN ISLANDS

S.L. Chown & C.H. Scholtz

Department of Zoology & Entomology, University of Pretoria, Pretoria, South Africa

The *Ectemnorhinus*-group of weevils is a monophyletic unit within the Brachycerinae (*sensu* Kuschel), endemic to the South Indian Ocean Province Islands of the sub-Antarctic region, i.e. the Prince Edward Islands, Crozet and Kerguelen archipelagos, and Heard and McDonald Islands. Phylogenetic analysis has demonstrated that the adelphotaxa for the *Ectemnorhinus*-group are the genera *Heterexis* Broun and *Oclandius* Blanchard which occur on the Auckland and Campbell Islands. It is suggested that the weevil faunas of the Crozet and Kerguelen archipelagos were derived following vicariance with East Antarctica and via Antarctica, New Zealand and its associated islands. Sub-Antarctic chironomid taxa show similar relationships, suggesting that the faunas of the South Indian Ocean Province Islands were derived partly from New Zealand. The weevil faunas of the New Zealand sub-Antarctic islands have close relationships with those of New Zealand, and likewise the Falklands fauna, and that of Gough and Tristan da Cunha, appear to be derived from those of South America. Curiously, weevils are absent on both South Georgia and Macquarie Islands. The weevil faunas on all of the sub-Antarctic islands appear to have been affected dramatically by Neogene climatic fluctuations. In the *Ectemnorhinus*-group this can be seen most clearly in a switch from angiosperm to cryptogam feeding, and reduced species richness in the basal, angiosperm-feeding taxa. The cryptogam-feeding genus *Bothrometopus* diversified during glacial periods when angiosperms were absent from the islands. The biogeographic patterns shown by sub-Antarctic weevils argue for a more comprehensive re-assessment of the biogeography of southern ocean islands.

02-035

FLYING THE SOUTHERN HEMISPHERE

Peter S. Cranston

CSIRO Division of Entomology, Box 1700, ACT 2601, Australia

The pioneering work of Lars Brundin in developing an explicit biogeographical method that reconciled the histories of biota and earth (phylogenetics and geology) of the cool temperate southern hemisphere remains very influential. Brundin recovered the orderly pattern of geological fragmentation of a pre-Jurassic Gondwanan supercontinent from the current distributions of certain midges (Chironomidae: Diptera).

Additional southern African-Australian chironomid associations confirm and expand the proposed biogeographical relationships. Elsewhere amongst the Diptera, comparable austral patterns are apparent (although sometimes differing in the relationships inferred for New Zealand) within the Trichoceridae, Tipulidae, Dixidae, Simuliidae, Thaumaleidae, Perissomatidae, several families of Mycetophiloidea, and in the Brachycera in at least the Pelecorhynchidae, Tabanidae and Rhagionidae. Entomologists increasing are comfortable with these ancient vicariant patterns and the ages they imply. However, we may be blinded to alternative faunal linkages between more tropical areas (some of which are no longer "austral" in that they are north of the equator). Patterns of faunal association between northern Australian insects and those of "Asia" were recognized early, and interpreted as due to recent dispersal from Asia (i.e. post-Miocene austro-Asian contact). Increasing evidence from the Chironomidae demonstrates concerted patterns of intra-generic faunal connections between central Africa, Madagascar, southern India and Sri Lanka, parts of south-east Asia and northern Australia. This pattern - Croizat's Indian Ocean baseline - requires no invocation of dispersal as an explainer but is an alternative (warm/eurythermic) vicariant Gondwanan pattern.

This evidence suggests that systematic studies that are restricted to a single region, lacking a wider biogeographical framework, or interpreted within only one austral vicariant pattern, may be deficient.

02-036

THE SYSTEMATICS AND BIOGEOGRAPHY OF THE AUSTROMIRINI (HETEROPTERA: MIRIDAE: ORTHOTYLINAE)
G. CASSIS (1) and A. ASQUITH (2)
1 - Australian Museum, Sydney, Australia; 2 - U.S. Fish and Wildlife Service, Honolulu, Hawaii, USA

The Austromirini are defined as a monophyletic tribe of the mirid subfamily Orthotylinae (Heteroptera: Miridae) on the basis of characters of the mesothoracic pleura and the genitalia. The tribe contains 36 genera and is found in all Australian states and territories, New Guinea and Hawaii. Australia is the centre of diversity where 34 genera occur, one of which also occurs in New Guinea. Two Hawaiian endemic genera are assigned to the tribe for the first time. A phylogenetic scheme for the genera has been developed and the biogeographic patterns within Australia will be outlined. The area relationships within Australia will be discussed in terms of current models such as Cracraft (1991). The biogeographic disjunction of the Austromirini between Australia + New Guinea and Hawaii will also be discussed in relation to Pacific Basin biogeography and determining the origins of the Hawaiian mirid fauna (Asquith, 1995)

02-038

PHYLOGENETIC RELATIONSHIPS AND CLADISTIC TEST OF THE EVOLUTIONARY CORRELATION BETWEEN OVIPOSITOR STRUCTURE AND OVIPOSITION HABITS OF *SCOTUSSA* AND *LEIOTETTIX* (ORTHOPTERA: ACRIDIDAE)

M.M. Cigliano, R.A. Ronderos¹, W.P. Kemp²

Departamento Entomología, Museo de La Plata, Argentina. 1 Deceased.
2. United States Department of Agriculture, Agricultural Research Service, Rangeland Insect Laboratory, Bozeman, Montana, USA.

A cladistic analysis of the South American grasshopper genera *Scotussa* and *Leiotettix* was performed to test the monophyly of these genera. Characters from the external morphology, male genitalia and female ovipositor were used in the analysis. The association between the structural change that occurred in the ovipositor valves of *Scotussa* and the functional change of the oviposition habits were tested. Information on oviposition habits and geographic distribution was then mapped on the cladogram, to determine the transformation sequence for performance and shift in the environment. Results confirmed the monophyly of *Leiotettix* and *Scotussa*. They also support the hypothesis of association between the structural change that occurred in the ovipositor valves of *Scotussa* with the functional change in the oviposition habits. However, this association did not seem to be correlated with the adaptive radiation in the genus.

02-037

THRIPS ON THE GREAT SOUTHERN ARK

Laurence A. Mound

Department of Entomology, CSIRO, Canberra, Australia.

Australia, the Great Southern Ark, presumably carried with it a considerable fauna of Thysanoptera when it first separated, 60-40my BP, from the southern continent. Most of this fauna may not have survived subsequent periods of aridity, as the continent moved north through 20 degrees of latitude to its present position. The modern thrips fauna is not well-known, less than half of the presumed 1000 species having been described. Two genera in the basal clade of the Order are evident relicts, associated with Proteaceae in the moister regions of the South West. One, *Dorythrips*, is shared with western South America, and the other, *Cranothrips*, with South Africa. One genus in the most derived clade, *Pseudanaphothrips*, is presumed to be the sister-genus of the largest Neotropical genus, *Frankliniella*. But most of the thrips fauna, like the flora on which it is dependant, appears to be autochthonous and is particularly associated with the eremaeon zone. In contrast, recent field work in northern Australia has produced considerable numbers of species with distributions to the North to India and Taiwan. Presumably these faunal elements postdate the Miocene collision of the Australian plate with the Sunda arc, and result from the wind systems that now blow South from Indonesia in the early months of each year. The effect of this on the concept of an 'Australian fauna' will be discussed.

02-039

CLADISTIC BIOGEOGRAPHY OF ASILOID FLIES (DIPTERA: ASILOIDEA) ON GONDWANALAND FRAGMENTS

D.K Yeates, M.E. Irwin¹

Department of Entomology, The University of Queensland, Brisbane, Queensland 4072, Australia - 1 Department of Natural Resources and Environmental Sciences, University of Illinois, 1101 W. Peabody, Urbana IL 61801 USA

Flies of the family Apioceridae have a disjunct distribution, occurring on each of the southern continents of Australia, South America, Africa and in North America. A cladistic analysis based on 77 features of adult morphology revealed that the Apioceridae as currently conceived is paraphyletic. The subfamily Megascelinae, including the genera *Megascelus* Philippi, *Tongamyia* Stuckenberg and *Neorhaphiomidas* Norris, was transferred to the Mydidae to maintain a monophyletic taxonomy. The genus *Apiocera* Westwood is composed of four monophyletic subgenera, one in each disjunct area of distribution. The relationships of the subgenera of *Apiocera* and the genera of the Megascelinae are examined in relation to the vicariance of Pangaea and the breakup of Gondwanaland.

02-040

THE AUSTRALIAN MOTH FAMILY ANTHELIDAE (LEPIDOPTERA : BOMBYCOIDEA) - COMMENTS ON BIODIVERSITY, BIOGEOGRAPHY, AND PHYLOGENY

K. D. Fahey

Department of Crop Sciences, Faculty of Agriculture,
University of Sydney, Sydney NSW Australia 2006.

The Anthelidae is a family of about eighty described species of medium to large moths, whose distribution is restricted to Australia and New Guinea. Eight genera are recognised from mainland Australia, and four of these are also found in Tasmania. Only one of these eight Australian genera is found in New Guinea, where there is a ninth genus, which is not found either in Tasmania or on the Australian mainland. The Anthelidae belong to two distinct subfamilies: the Anthelinae, with about seventy five described species in seven genera; and the Munychryiinae, with three species in two genera.

To fully appreciate the biodiversity of the Anthelidae, it is necessary not only to look at the phylogeny of the nine genera. One genus, (*Anthela*), includes the majority of the described species, (sixty), and most of these belong to one of several clearly recognisable species groups. The present distribution of these species groups, and speciation within the groups, is often linked to that of their host-plant genus or family. That, in turn, is the result of the climatic and geological history of the continent of Australia.

Several tentative scenarios of both the biogeography and phylogeny of the family Anthelidae are suggested. Its inclusion here, within the Superfamily Bombycoidea (rather than its separation from the Bombycoidea, and inclusion, with the Lasiocampidae, as the Superfamily Lasiocampoidea), is at present fully justified. Many more years work, will probably be required to fully clarify the biogeography and phylogeny of the family Anthelidae.

02-041

ARE INSECTS AS DIVERSE AS THE PLANTS IN THE CAPE FLORISTIC REGION?

J.H. Giliomee

Department of Entomology and Nematology, University of Stellenbosch, Stellenbosch, South Africa.

The Cape Floristic Region is characterized by high plant species diversity (more than 8500 species on 90 000 square km) and a remarkable degree of endemism (69 percent for species). As regards the fauna, the mammals and birds are comparatively species poor with a few endemics while the reptiles and amphibians are species rich with many endemics. This information is not available for the insects because of inadequate comparative sampling, and lack of knowledge about the identity and distribution of species. However, by comparing the number of species in certain well-known groups, such as grasshoppers, butterflies, ants and gall insects from specific areas with those of other regions, it is concluded that the insect diversity is not particularly high. The same appears to be true for the degree of endemism, except in specific taxa. It is speculated that this is probably the result of the low nutrient status of the soil, the sclerophyllous nature of the vegetation, the low levels of detritus on the soil surface and frequent fires.

02-042

PATTERNS OF INSECT DIVERSITY IN AUSTRALIA'S TROPICAL MONTANE RAINFORESTS AND THEIR USE FOR CONSERVATION ASSESSMENT

G.B. Monteith

Queensland Museum, Brisbane, Queensland, Australia.

The Wet Tropics Zone of Australia is a belt of rainforested mountains about 450km long and 70km wide running from 16° to 19° S along the coast of north Queensland between Cooktown and Townsville. The mountains themselves are geologically old (mostly Mesozoic granites) and, by Australian standards, comparatively high. Some exceed 1600m, making them the second highest mountains in Australia. Their montane zones support many relict organisms which date from the gondwanan connection of Australia with Antarctica. Among insects these include many "tropical" occurrences of taxa otherwise occurring only in southern temperate environments, e.g. migadopine carabids, myerslopiine leafhoppers and peloridiid moss bugs. The region has the richest flora and fauna in Australia and was made a World Heritage Area in 1988.

An intensive survey of several target taxa of forest floor insects has been carried out over the last 15 years. The taxa chosen were those with a high proportion of flightless species which would more strongly reflect the historic patterns of distribution. These taxa were the carabid beetles, the adeliine and coelometopine tenebrionid beetles and the aradid bugs.

Fifteen thousand specimens of 265 species of these taxa were collected from more than 350 localities using pitfall traps, intercept traps, litter extraction, pyrethrum spraying and day/night hand collecting. Mapping and analysis of the distribution records showed that many species have very restricted distributions and that the fauna of different mountain massifs varies radically, both quantitatively and qualitatively. Certain massifs proved preeminent as refugia and centres of diversity. Using the collection data, which had been collected uniformly across the region, a Rare and Restricted Index was calculated for each species. This Index ranged from 1 to 20 and comprised components from five aspects of the data, viz. number of specimens collected, number of times encountered, number of localities encountered, number of sub-zones encountered, and altitudinal restriction. Thus species known from a single specimen from high altitude achieve a score of 20 while those collected many times at many localities at all altitudes score close to zero.

Calculating means or sums of the Indices of all the species on each of 39 individual mountain massifs of the region allows the massifs to be ranked in terms of the relative size, endemism and rarity of their insect faunas. This gives a simple tool to assist decisions regarding the conservation management of different parts of the Wet Tropics World Heritage Area.

02-043

BIODIVERSITY ASSESSMENT USING LEPIDOPTERA — SELF INTEREST OR COLLECTIVE INTEREST?

R.I. Vane-Wright

Biogeography & Conservation Laboratory, Department of Entomology,
The Natural History Museum, London SW7 5BD, UK

At a conservative estimate, there are about 250,000 species of Lepidoptera living today. Their conservation on an individual, species-by-species basis is not a practical option, so the fate of all but a few (other than those favoured, or not threatened by human activities) will depend on the selection and maintenance of suitable habitats. Networks of conservation areas, even when they are planned with a representation goal in mind, are normally based on the analysis of vertebrate distribution patterns, or on vegetation or land classifications. There is, however, no compelling empirical evidence or theoretical reason to expect that networks based on vertebrate data, or other, more remote biodiversity surrogates, will be fully effective, or maximally efficient for the conservation of Lepidoptera (or any other non-focal taxon). Lepidoptera may need action plans in their own right. Alternatively, they may have potential to act as surrogates for other, less well-known elements of biodiversity, through analysis at species or higher-taxon level, or as part of a suite of focal taxa for biodiversity assessment by summation. Finally, they may also help to identify areas of endemism, a largely untested approach to conservation evaluation. The talk will be illustrated with examples of research currently in progress, mainly drawn from work on Papilionoidea and Bombycoidea being carried out at the Biogeography and Conservation Laboratory of The Natural History Museum, London.

Biodiversity of Lepidoptera: background and application. R. de Jong & M. Scoble

02-044

LEPIDOPTERA AS AN 'UMBRELLA GROUP' FOR INSECT CONSERVATION.

T.R. New
School of Zoology, La Trobe University, Bundoora, Victoria, Australia.
Much of the development of insect conservation has directly involved studies on butterfly species or subspecies, or has been stimulated by these. Butterflies have thereby become the most important 'flagship' group of insects in practical conservation. Species-level focussing may be impracticable for more diverse groups, including many moths. The ecological complexities collectively, manifest by Lepidoptera, together with increasing taxonomic tangibility of many groups and the ease of sampling them, can be used to promote the worth of butterflies and moths as an umbrella group, capitalising on existing public and official sympathy and extending appreciation of insect diversity and ecological values. Opportunities for broad promotion of insect conservation in many parts of the world using Lepidoptera are explored and discussed.

02-046

BIOLOGICAL COLLECTIONS AND BIODIVERSITY
STUDIES OF LEPIDOPTERA
S. Nielsen (Canberra-Australia)

ABSTRACT NOT RECEIVED

02-045

USING TAXONOMIC DATA IN BIODIVERSITY STUDIES ON THE LEPIDOPTERA
M J Scoble
Department of Entomology, The Natural History Museum, London, U.K.

The Lepidoptera, particularly butterflies and large moths, are well represented in insect collections. Basic taxonomic details in digital form now exist for a substantial portion of the Macrolepidoptera.

A taxonomic database of the Geometridae is substantially complete. The mechanics of this project show that it is perfectly possible to produce life-lists of large insect taxa within a relatively short period of time. Such information has been requested frequently by the biological community - particularly in recent years.

Details of the geometrid database will be presented, and use of the information in studies of species richness explained.

02-047

INVASIONS OF LEPIDOPTERA AND THEIR EFFECT ON BIODIVERSITY.
D.J.L. Agassiz
CAB International Institute of Entomology, London, UK

Invasions are defined and distinguished from migration and artificial introductions. Data are presented on lepidoptera which have successfully invaded the British Isles during the last 100 years. Further data quantify extinctions, and the last sightings of species which have not been recorded for over 25 years.

Many extinctions can be attributed to changes in land use and other factors, rather than to competition with other species of lepidoptera. Examples from plants and mammals show tht invasive species do affect native populations. Data from British lepidoptera are examined to explore whether there is any such link, however indirect, and how invasions relate to indices of diversity.

02-048

EVALUATING THE EFFICIENCY OF TARGET TAXA IN BIODIVERSITY ESTIMATION: MYCALESINE BUTTERFLIES IN MADAGASCAR.

D.C. Lees¹, C. Kremen²

Biogeography and Conservation Laboratory, Department of Entomology, Natural History Museum, London, U.K. - 1
Wildlife Conservation Society, Ampasapito, Antananarivo 101, Madagascar -2

Madagascar is a global biodiversity hotspot. Its biodiversity is poorly known, and only 6% of its remaining primary forest is protected; even this protected forest is threatened by a spectrum of human-related causes. For efficiency in survey work and conservation strategy, it would be useful if we could estimate biodiversity patterns from knowledge of a well studied group. In the U.K. at least, local hotspots do not always coincide. In Madagascar, however, the primary rainforest biome (mostly still contiguous except at lower elevations) provides a more promising test. Because surviving rainforest organisms there share a common evolutionary theatre and ecological play, there is a much better chance that diversity patterns may show congruence—especially when the target group has undergone an extensive local adaptive radiation, as has happened in one subtribe of satyrine butterflies, the Mycalesina. As a result of recent work on this group, species definitions, phylogenetic relationships and distributions are now better understood than for most other Madagascan invertebrates. To assess the potential of the target taxon approach, patterns for mycalesines are compared with those for other well known rainforest taxa.

02-050

PHYLOGENY OF THE OLD WORLD YPONOMEUTIDAE S.STR. (LEPIDOPTERA). A TOOL FOR THE FORMULATION OF SCENARIOS OF SPECIATION

Sandrine A. Ulenberg & Zlata S. Gershenson¹

Institute for Systematics and Population Biology (Dept. of Entomology, Zoological Museum Amsterdam), University of Amsterdam, The Netherlands - 1 Institute of Zoology, National Academy of Sciences of the Ukraine, Kiev, Ukraine

The morphology of the *circa* 200 Old World species of the moth family Yponomeutidae has been investigated. The relationships within the Yponomeutidae have been worked out on basis of cladistical analyses of the morphological differentiation among the species. Previous hypotheses concerning relationships among the Yponomeutidae are reviewed and new hypotheses will be presented.

Special reference will be made to the genus *Yponomeuta* Latreille. This palaearctic genus has been studied as a model system for the evolution of insect-plant associations and speciation in phytophagous insects since the early seventies.

Scenario's for processes of speciation within the genus *Yponomeuta* are obtained by superposing characters that might act as isolating mechanisms such as geographical distribution, host plant association and sex pheromone communication onto the independently derived estimate of the phylogenetic relationships among the species.

The scenarios are formulated along with the sequences of character changes dictated by the cladograms presented here. Simultaneously, the restrictions to the processes imposed by the cladograms will be discussed.

02-049

BUTTERFLIES AND PLANTS: A PHYLOGENETIC STUDY

N. Janz, S. Nylin

Department of Zoology - Stockholm University -106 91 Stockholm, Sweden

A database on host plant records from 437 ingroup taxa has been used to test a number of hypotheses on the interaction between butterflies and their host plants using phylogenetic methods. Previous studies suggest that the patterns of association in most insect-plant interactions are more shaped by colonizations, host shifts, and specialization than by cospeciation. Consequently, in this paper we have focused explicitly on the mechanisms behind host shifts and changes in host range.

The ancestral host plant appears to be located within a highly derived Rosid clade, which includes Fabaceae, Urticales, and Rosaceae. Host shifts have been more common between closely related plants than between more distantly related plants. Plant growth form turned out to be an even more conservative aspect of the interaction between butterflies and their host plants than plant phylogeny. However, this is largely explained by a higher probability of major host shifts while feeding on trees than on other growth forms. There was also a strong association between tree-feeding and a large host range, but no support at all for the view of specialization as an evolutionary "dead end". Instead, most lineages appear to have undergone repeated instances of polyphagy, followed by re-specialization. These three last results together suggest a possible general pathway for host shifts, via a polyphagous state on trees.

02-051

SYSTEMATICS AND BIOGEOGRAPHY OF AFRICAN MACARIINI (LEPIDOPTERA: GEOMETRIDAE: ENNOMINAE)

M. Krüger

Lepidoptera Department, Transvaal Museum, Pretoria, Republic of South Africa

Revision of the macariine fauna of Africa, Madagascar and Arabia resulted in major changes to the global taxonomy of the group on generic and tribal levels.

A total of 264 species, 93 of which are described as new, are recognized. These species are distributed very unevenly over 15 genera, eight of which are new to science.

Following cladistic analysis of macariine genera on a worldwide basis, a subdivision of the study group into two subtribes, Platypeplina and Macariina, is proposed.

Within the larger genera, numerous monophyletic species-groups are present, many of which exhibit associations with one of the major biomes. It is hypothesized that the two largest genera, *Itame* Hübner and *Chiasmia* Hübner, have speciated extensively in the savanna biome of Africa during the Cenozoic, as their derived species-groups are almost entirely confined to savanna habitats today, whereas many of the less derived groups occur in the older forest biome. The 'modern' species-groups of both genera are also completely absent from Madagascar, which has been separated from the African continent since the late Mesozoic. Based on present-day distributions and phylogenetic information, evidence is presented for a post-Gondwanan origin of Macariini in the Afrotropical region.

02-052

NOTES ON THE CLASSIFICATION OF AMERICAN INCHWORM MOTHS IN THE SUBFAMILY STERRHINAE (LEPIDOPTERA, GEOMETRIDAE).
 Charles V. Covell Jr.
 Department of Biology, University of Louisville, Louisville, KY USA

The smallest inchworm moths are members of the worldwide subfamily Sterrhinae, and comprise more than 2,378 species in 100 genera. Nearly 1,000 species representing 6 tribes have been described from the Americas.
 Because of their polymorphism and the geographic interests of previous workers, much synonymy and confusion exist. While the status of the 103 North American species has been updated, most of the vast neotropical fauna remains to be worked out. Some genera, such as those of the diurnal tribe Cylopodini seem out of place as currently classified in the subfamily.
 The author comments on the current status of classification and proposes a program to elucidate the true status of these moths by collaboration with workers in Central and South American countries such as Costa Rica (through INBio) and Ecuador.

02-054

R.C.L. PERKINS AND THE FAUNA HAWAIIENSIS: WHAT LONGTERM DATA CAN TELL US ABOUT HAWAIIAN DIVERSITY
 J.K. Liebherr, D.A. Polhemus¹
 Department of Entomology, Cornell University, Ithaca, NY, USA -
¹ Department of Biological Sciences, Bernice Pauahi Bishop Museum, Honolulu, HI USA

From 1893 to 1897, R.C.L. Perkins conducted a faunal survey of Hawaiian animals that formed the basis for the Fauna Hawaiiensis. This survey, conducted by a single individual who kept substantial field records, and who noted specific sites that can be revisited today, resulted in taxonomic material that provides a valuable basis for comparison 100 years later. In addition, Perkins' notes can be tied to specimen voucher lots, making biological phenomena such as relative abundance, phenology, way of life, and habitat type discernible from his collections. We first focus on the immense impact introduced animals and plants have wreaked on native Hawaiian ecosystems over the past 100 years and more; a fact lamented even by Perkins. We then compare diversity estimates derivable from Perkins' collections with those made during later decades using two model groups; *Megalagrion* damselflies (Odonata) and platynine carabid beetles (Coleoptera). Both groups have been extensively surveyed on all islands in the 1990's, with many of Perkins' collecting sites revisited. Profiles of relative abundance for relatively undeveloped Molokai deviate little from the 1890's to present, indicating that in protected montane areas, populations of native damselflies and carabids have not been impacted by biotic change or habitat destruction. A single potential extinction, the terrestrial breeding *Megalagrion molokaiense* (Perkins), may have been compromised by ants. Conversely, on highly developed Oahu, many rarer taxa, and one previously common carabid, *Colpocaccus tantalus* (Blackburn), have not been observed during the present decade.

02-053

A PRELIMINARY ANALYSIS OF THE PHYLOGENY OF THE POLYOMMATINI (*Polyommatus* GROUP OF GENERA, SENSU ELIOT)
 Emilio Balletto
 Dipartimento di Biologia Animale, University of Torino, Italy
 The Polyommatini represent a rather homogeneous assemblage of genera, easily enough definable by the presence of a transversally split tergal sclerite (pseudotergum) in the male genitalia and of an extrovertible appendage (henia), in the female sex. Ideally, females take an active role in copulation, by seizing the highly reduced and barely protruding male's suprazonal part of penis by their external genital opening, placed on the tip of the henia. Other additional characters are represented, in the male sex, by a double, digitate, uncus accompanied by a pair of falx-shaped subunci, a U-shaped futura inferior (furca) and fusiform valvae. Males, moreover, normally have battledore shaped androconial scales. Not all these characters, however, are recognizable in all species and particularly some of the apparently least advanced genera may lack one or more of them. Conversely, at least in another non-Polyommatine genus such as *Lampides*, females have a non-extrovertible henia, whereas males do not show any trace of a pseudotergum. This genus is provisionally assumed to represent the sister group of the Polyommatini. Within the main Polyommatine lineage, however, specialization does not proceed linearly towards the acquisition of the most advanced genital structures and many of these acquisitions may well have been developed more than once, in different sub-lineages. In the present paper I will develop a preliminary phylogenetic analysis based on 67 mostly genitalic characters as observed in 42 genus-group taxa. A group of South and Central American genera appear to include the most primitive taxa of the Polyommatine lineage, which might have spread into the Holarctic realm only in comparatively recent times. Some of these more advanced genera may have, in turn, re-invaded South America.

02-055

RADIATION AND PHYLOGENY OF TETRAGNATHID SPIDERS (ARANEAE) IN HAWAII
 R.G. Gillespie
 Center for Conservation Research and Training, University of Hawaii, Honolulu, HI, USA.
 A large radiation of *Tetragnatha* endemic to Hawaii has been recently uncovered, which were previously known only from descriptions of 9 species, described on the basis of specimens collected in the 1890's by R.C.L. Perkins. Over the last few years an additional 19 species of Hawaiian *Tetragnatha* have been described and » 50 new taxa have been collected. This species radiation spans a huge spectrum of colors, shapes, sizes, ecological affinities, and behaviors, but form closely related lineages within the genus *Tetragnatha* based on palpal morphology, cheliceral structure, mating behavior, and molecular data. Many are web-building, with structural modifications of the abdomen that allow concealment within specific microhabitats. Some species have modifications of the cheliceral armature, apparently to allow specialization on specific prey types. However, several groups have abandoned the characteristic web-building behavior of the genus. For example, one entire clade of 16 species, has abandoned web building, with the concomitant development of long spines along the legs and adoption of a vagile, cursorial predatory strategy. In this paper I discuss patterns of speciation in the lineage, their relationship to habitat specialization, and the possible number and source of colonizations involved in the species radiation.

02-056

SYSTEMATICS AND EVOLUTION OF HAWAIIAN FULGOROIDEA (HEMIPTERA)

M. Asche

Institut für Systematische Zoologie, Museum für Naturkunde, Humboldt-Universität Berlin,
Berlin, Germany

With ca. 230 endemic species, the phytophagous Fulgoroidea or planthoppers are among the most significant elements of the native Hawaiian fauna. As predominantly mono- or oligophagous insects they play an important role in nearly all Hawaiian ecosystems. Species of only 2 out of worldwide 18 planthopper families have successfully colonized and subsequently radiated in Hawaii. Based on collections mainly made by Perkins, Kirkaldy, Muir, Giffard, and Swezey, more than 95 % of these species were discovered and described in the first two decades of this century. Recent inventories on all islands and especially studies on the intraspecific communication of selected planthoppers (e.g., cavernicolous taxa of the family Cixiidae) have revealed a much higher degree of diversity leading to an estimate of a total of 350-400 species. However, the taxonomy of this group still reflects the standard of the early century. Currently, on the basis of comparative morphology only few Hawaiian planthopper genera can be regarded as monophyletic, while others are evidently polyphyletic, including *Nesosydne*, the largest genus of Delphacidae in the Pacific which is also reported from areas outside of Hawaii (e.g., Marquesas, Society, and Galápagos Islands). While in Cixiidae apparently 2 independent primary colonizations of yet uncertain origin of the ancestral species have occurred, at least 5 primary invasions equally from an unknown source can be estimated for the Delphacidae. However, as long as the systematics of the Hawaiian planthoppers is not yet based on a phylogenetic analysis, any conclusions on biogeography and evolutionary history of this group may be rather tentative. A modern biosystematic study of the native Hawaiian planthoppers at all biological levels is proposed and will include morphological and molecular systematics, behavioral ecology, and population genetics; the latter especially in populations of cavernicolous taxa and those presumably co-evolved or co-evolving with certain hostplants or plant communities (e.g., a group of ca. 10 apparently closely related morphospecies of *Nesosydne* s. str. with *Acacia* kōa).

02-057

HAWAIIAN PSEUDOCOCCIDAE (HEMIPTERA), A GROUP THAT PERKINS MISSED.

J. W. Beardsley.

1026 Oak Dale Lane, Arcadia CA 91006, USA.

Among the 16 or so recognized families of Coccoidea, only Pseudococcidae and the small, specialized Halimococcidae are represented in the endemic Hawaiian fauna. Why other large coccoid families failed to establish there is unknown. The endemic Pseudococcidae of Hawaii presently include 31 described species in 13 genera. Ten genera are endemic. Around 40 undescribed endemic mealybug species belonging to both described and undescribed genera also are known. Perkins apparently collected no endemic mealybugs. Kirkaldy in *Fauna Hawaiiensis* listed the "Family Coccidae" (= Coccoidea) as absent from the endemic Hawaiian fauna. At least 5 or 6, possibly more, prehistoric colonizations of Hawaii by mealybugs were required to produce the existing fauna. Most of the endemic genera are so highly specialized that their relationships to extra-Hawaiian forms are obscure. However, some endemic species of *Pseudococcus* appear to be closely related to species in Australia and Pacific islands. This conclusion is based primarily on similarities in male genitalia; secondarily on female morphology. Endemic Hawaiian mealybugs are often cryptic, occupying habitats such as plant galls, rolled leaves, under bark and leaf sheaths of grasses. Those which occupy more exposed locations on foliage or twigs usually are cryptically colored or armed with large spines. These specialized habitats and morphologies appear to have evolved in response to pressure from predators.

02-058

THE PHYLOGENETIC ECOLOGY AND BIOGEOGRAPHY
OF HAWAIIAN *MEGALAGRION* DAMSELFLIES -
A CASE STUDY IN EVOLUTION

Dan A. Polhemus

Smithsonian Institution, Washington, D. C., USA

The damselfly genus *Megalagrion* as currently interpreted contains 28 species and subspecies, all endemic to Hawaii. An analysis of external morphological characters in both males and females has permitted a reconstruction of the phylogeny of this group, and the delimitation of major clades within it. This analysis clearly indicates that the presently existent clades within *Megalagrion* were established by at least the time the island of Kauai came into existence approximately 5 million years ago, and that members of these clades have moved sequentially down the chain as newer islands were created. Members of these clades also possess distinctive ecological preferences that are retained as new islands are colonized. These phylogenetically linked ecological traits are useful in a conservation context by allowing the prediction of ecological preferences in species for which this information is currently unknown.

02-059

THE HAWAIIAN DROSOPHILIDAE: A MOLECULAR
PERSPECTIVE.

R. DeSalle, Department of Entomology, American Museum of Natural History, New York, NY 10024.

There are probably over one thousand species of Drosophilidae distributed in two subgenera in the family that are endemic to the Hawaiian archipelago. The ecological, morphological and behavioral divergence of several of the species groups of Hawaiian Drosophilidae is well documented. In addition, the classical chromosomal analyses of Carson and his colleagues lends a genetic perspective to our understanding of the radiation. More recent molecular analyses can also contribute to our understanding of the group as this talk will demonstrate. Three major areas where molecules have contributed to our understanding of this interesting radiation will be discussed. All are related to a better understanding of phylogeny in the group. The first concerns species level phylogenetic analysis to better understand the biogeographic relationships of these organisms. Molecular phylogenies can be used to examine the patterns of interisland colonization and to give us some idea of the trends involved in the biogeography of the group. Another biogeographic problem that can be addressed using molecular analysis concerns the founding of the entire group on the archipelago. Using molecules as a source of characters a higher level phylogeny of Hawaiian taxa and continental taxa can address this question. The second area that this talk will address is the issue of ecological and morphological radiation. Higher level phylogenies can be used to understand patterns of cladogenesis in the group and to examine the correlation of morphological and ecological change in the group. The final area that molecular analysis can be of use is in the diagnosis of species. Using molecular characters the problem of species designation of *Drosophila silvestris* and *Drosophila heteroneura* on the Big Island of Hawaii will be examined.

02-060

ADAPTIVE RADIATION IN THE HAWAIIAN DROSOPHILA:
ECOLOGICAL AND REPRODUCTIVE CHARACTER ANALYSES

E.M. Craddock, M.P. Kambyssellis¹
Division of Natural Sciences, Purchase College,
State University of New York, Purchase, NY USA-
¹ Department of Biology, New York University,
New York, NY USA

The entomologist R.C.L. Perkins pioneered observations of the breeding site ecology of the endemic Hawaiian Drosophilidae, a renowned group of flies that has undergone explosive speciation and adaptive radiation into a wide variety of breeding niches. Females of the various species groups and subgroups oviposit their eggs in fungi, decaying flowers, fruits, leaves, stems, bark, tree fluxes, or even spiders' eggs, in a few cases. Varied selective forces in these alternative niches have molded female reproductive characters and strategies into diverse outcomes; some species mature and oviposit only one egg at a time, whereas others oviposit hundreds.

Recent molecular phylogenies of Hawaiian drosophilid species based on nuclear and mitochondrial DNA sequences permit phylogenetic tracing of the evolutionary shifts in female behavioral and morphological aspects of reproduction, and reconstruction of the history of the remarkable adaptive radiation of this fauna. Phylogenetic character analyses to be presented focus on aspects of female ovipositional choice, and ovarian, ovipositor and egg chorion morphology. The correlations among behavioral, morphological and ecological traits, and adaptive aspects of character evolution in the Hawaiian drosophilid fauna will be analyzed.

02-062

PHYLOGEOGRAPHY OF PLANTHOPPERS
(HEMIPTERA) AND TEPHRITIDS (DIPTERA) ON THE
SILVERSWORD ALLIANCE: PARALLEL SPECIATION
OR CO-EVOLUTION?

G.K. Roderick

Center for Conservation Research and Training, University
of Hawaii, Honolulu, HI 96822 USA.

Insect species in several lineages feed exclusively on plant species in the Hawaiian silversword alliance (Asteraceae). These lineages include species of delphacid (*Nesosydne*) planthoppers and tephritid (*Trupanea*) flies. For both lineages, phylogenies based on molecular data, are presented for insect species collected from plant species within the Hawaiian silversword alliance. The patterns of radiation for the insects are compared to that generated for their host plants in the alliance, also based on molecular data (from B. G. Baldwin and R.H. Robichaux 1995). Co-speciation is found to be significant between planthoppers and their hosts, but less so for tephritids. I also examined the role that hybridization between members of the Hawaiian silversword may play in the diversification of plant feeding insects. Host plant hybridization may create "resource sinks," such that insect species from both parental plant species are found on hybrids, or alternatively, the hybrids may serve as "bridges," by which insects of one parental plant species move to hybrids and then onto new hosts. These hypotheses are explored by examining the relationships of insect species found on hybrid and parental plant species.

02-061

THE HAWAIIAN DROSOPHILIDAE: WHERE DO WE
GO FROM HERE?

K.Y. Kaneshiro

Center for Conservation Research & Training, University of Hawaii,
Honolulu, Hawaii, USA 96822

More than three decades of research on the evolutionary biology of Hawaiian Drosophilidae have made significant contributions to the understanding of evolutionary processes on islands. While the first ten years of the project involved field studies to determine the extent of the biodiversity of this group, the last 20 years have focused on unravelling genetic mechanisms of speciation primarily on one group of species, the picture-winged species group. Detailed morphological, cytological, biochemical, developmental, and molecular studies have been conducted on this group of about 100 species by more than 50 researchers from the U.S. and abroad.

We are just beginning to investigate the biosystematics of the other groups in the Hawaiian Drosophilidae. Detailed morphological analyses of the modified mouthparts and modified tarsus groups are in the early stages; ecological, developmental, and molecular studies of these groups are also proposed. While the picture-winged species have provided excellent subjects for evolutionary studies, the remaining species in this remarkable fauna will provide important insights into the evolution of some of the bizarre secondary sexual structures observed in dipteran species. Scanning micrographs will show the elaborate development of these structures and their possible sensory role in the courtship displays of the males.

02-063

DISPERSAL AND VICARIANCE IN HAWAIIAN PLATYNINE
CARABID BEETLES (COLEOPTERA)

J.K. Liebherr

Department of Entomology, Cornell University, Ithaca, NY, USA

The Hawaiian Islands support a substantial native carabid beetle fauna, with 129 of the approximately 300 native species comprising a monophyletic radiation within Tribe Platynini. Overall, 125 of these 129 species are single island endemics; all 24 species from Kauai, 33 of 34 species from Oahu, 17 of 21 from Molokai, 3 of 5 from Lanai, 13 of 17 from West Maui, 31 of 35 from Haleakala, and 4 of 6 from Big Island. Cladistic analysis of the 129 native species plus 41 outgroup taxa, based on 204 morphological characters, indicates that island colonization within the chain is almost completely progressive, with the origin of the fauna on Kauai. Outgroup area relationships are somewhat ambiguous, with the Australian *Notagonum submetallicum* White patristically closest to the Hawaiian radiation. Extensive endemism on the separate volcanoes comprising Maui Nui allows comparison of vicariant patterns among Molokai, West Maui and Haleakala. Five resolvable three-species triplets occupy the three islands; three exhibit a Molokai-West Maui sister relationship, and two support West Maui and Haleakala as most closely related. Four other species are widespread across the three islands. These patterns are analyzed in light of elevational range of known habitat, relative abundance, phylogeny, and way of life. Elevational range and relative abundance correlate best with the type of vicariant pattern observed, whereas way of life correlates best with presence or absence of speciation. The colonization of Big Island is presented as a model of previous island colonizations. The six Hawaii species are derived from at least five colonization events, three involving winged progenitors, two involving vestigially winged progenitors, and all from a source on adjacent Maui Nui.

02-064

INSECTS IN A CHANGING WORLD.

F. Kozár

Plant Protection Institute, Hungarian Academy of Sciences, H-1525
Budapest P.O.Box 102, Hungary

I. Distribution. Significant northward movement of several southern insect species was observed in the last years in different parts of Europe, by average speed of 20-50 km/year. In some cases by "jumping dispersion", insects could reach 700 km in a very short time. In a lesser extent some species showed south east extension of their distribution. What could be explained by the relatively cold summers, observed in this region in the years with mild winters.

II. Population dynamics. New outbreaks of thermophilous insects were observed in different countries, such as *Dociostaurus maroccanus* in Hungary. The new outbreaks of *Ceratitis capitata*, *Helicoverpa armigera* in South Europe, were followed by northward migrations of these pests in Europe.

III. New introductions. In Europe several important new introduced pest species were observed, such as *Diabrotica virgifera virgifera* in Serbia, two *Ragoletis* species in Italy and Switzerland, etc.

IV. Phenology. In some countries after mild winters, warmer spring was observed, with subsequent earlier beginning of the phenological changes on the insects, but the changes are very slow, about 7-10 days/100 years. In contrary, in Central Europe after milder winters colder springs were observed, with later appearance of insects.

The northward expansion, the new outbreaks, introductions and northward migrations of several thermophilous insect species could be explained with long period of years with mild winters, and with hot summers.

02-066

INFLUENCES OF CLIMATE FLUCTUATIONS ON INSECT DIVERSITY PATTERNS DETECTED BY LONG-TERM LIGHT TRAPPING

F. Szentkirályi¹, K. Leskó², F. Kádár¹

¹ Department of Zoology, Plant Protection Research Institute of the Hungarian Academy of Sciences, Budapest, Hungary - ² Department of Forest Protection, Forest Research Institute, Gödöllő, Hungary

It is important to monitor the effects of climate change on communities of living organisms. The insects are suitable bioindicators of the fluctuations of the climatic variables due to their rapid responsibility.

The authors have studied the transformations and fluctuation patterns of insect diversity depending on climatic variations in Hungary during the last 34 years. Long-term yearly light trap captures of macrolepidoptera (1962-95), predatory brown lacewing and antlion (Neuroptera: Hemerobiidae, Myrmeleontidae) (1981-95) assemblages were used for analyses. The light trap network stations were operated inside forested and agricultural habitats in both lowland and highland regions.

The monthly climatic characteristics (temperature and precipitation variables) and various drought indices were calculated from data sets of the standard network of Hungarian Meteorological Service.

Time series analytical methods were applied to characterize the changes in the patterns and to detect the influences of climate variations. Various indices and functions (species richness, H', alpha, Q, etc.) served for description of diversity patterns.

02-065

1945-1995: FIFTY YEARS OF INCIDENTAL INSECT PEST INTRODUCTION TO ITALY

G. Pellizzari, L. Dalla Montà. Istituto di Entomologia Agraria, Università di Padova, Italy.

More than one hundred exotic insect pests have been introduced to Italy in the years between 1945-95. They are mainly pests of ornamentals, woody plants and Citrus. Some of them are pests of medical and domestic importance (i.e. *Aedes albopictus* (Skuse)). The three orders accounting for most of the introductions are the Homoptera (70% of the total number of introduced species), Coleoptera (10%), Lepidoptera (7%). The majority of introduced species have come from North America (26%), Asia (25%), Central and South America (12%), Africa (10%) and Australia (7%). Some introduced species failed acclimatization because of adverse climatic factors or extermination of the focus (i.e. *Demyrsus meleoides* Pascoe on *Cycas*, *Limacoccus brasiliensis* (Hempel) on *Arecastrum*). Many introduced species persist only in greenhouse: (i.e. *Pseudococcus microcirculus* McKenzie on orchids, *Rhizoecus dianthi* Green and *R. saintpauliae* Williams on ornamentals). Several species have succeeded in acclimatizing and nowadays are widely distributed throughout Italy but with low population densities (i.e. *Diaspidiotus osborni* New. & Cock. on plane, *Dasineura gleditsiae* (Osten Sacken) on *Gleditsia*). In other cases the introduced and acclimatized pest has not spread from the first focus noticed but persists as a local pest (i.e. *Epithrix hirtipennis* (Melsh.) on tobacco *Gonipterus scutellatus* Gyllenhal on Eucalyptus). Many species have succeeded in acclimatizing and in spreading and are now largely distributed at high population densities throughout Italy (i.e. *Ceroplastes japonicus* Green *Hyphantria cunea* Drury, *Frankliniella occidentalis* (Pergande)). In some cases Italy has been the first noticed focus of an exotic pest in Europe. From this first focus the pest has expanded throughout Italy and towards neighbouring countries (i.e. *Corythuca ciliata* Say on plane, *Metcalfa pruinosa* Say *Paratopopoda robinella* Clemens on locust-tree).

02-067

NORTH AMERICAN FOREST INSECTS AND CLIMATE CHANGE: POTENTIAL CHANGES IN GEOGRAPHICAL DISTRIBUTION OF DEFOLIATOR SPECIES

D.W. Williams, A.M. Liebhold¹

USDA Forest Service, Northeastern Forest Experiment Station, Radnor, PA USA - ¹ USDA Forest Service, Northeastern Forest Experiment Station, Morgantown, WV USA

The geographical ranges and spatial extent of forest defoliator outbreaks are likely to shift with climate change. We investigate potential changes in spatial distribution of outbreaks of the western spruce budworm, *Choristoneura occidentalis* Freeman, and the gypsy moth, *Lymantria dispar* (L.), in the United States using maps of historical defoliation, climate, and forest composition in a geographic information system. Maps of defoliation frequency were assembled from historical aerial reconnaissance data. Maps of monthly means of daily temperature and of monthly precipitation averaged over 30 years were developed using an interpolation technique. Relationships between defoliation status and environmental variables were modeled with a linear discriminant function. Five climate change scenarios were investigated: an increase of 2° C, a 2° increase with an increase of 0.5 mm per day in precipitation, a 2° increase with an equivalent decrease in precipitation, and equilibrium projections of temperature and precipitation by two general circulation models (GCMs) at 2×CO₂.

With an increase in temperature alone, the projected defoliated area decreased relative to ambient conditions for the budworm and increased slightly for the gypsy moth. With an increase in temperature and precipitation, the defoliated area increased for both species. Conversely, the defoliated area decreased for both when temperature increased and precipitation decreased. Results for the GCM scenarios contrasted sharply.

02-068

TEMPORAL AND SPATIAL FLUCTUATION PATTERNS OF MOTHS UNDER CLIMATIC CHANGE IN HUNGARY

K. Leskő¹, F. Szentkirályi², F. Kádár²

¹ Department of Forest Protection, Forest Research Institute, Gödöllő, Hungary

² Department of Zoology, Plant Protection Research Institute of the Hungarian Academy of Sciences, Budapest, Hungary

Recently some characteristic trends in climate pattern have been detected in Hungary (e.g. series of mild winters and decreasing amount of rainfall with frequent droughts). The authors have analysed the effects of these trends and climatic variables on temporal and spatial fluctuation patterns of moths. The macrolepidoptera data sets (1962-95) were based on the catches of forestry light-trap network. The total yearly captures were applied in order to characterize the fluctuation pattern-types of moths. Monthly and yearly values of precipitation, mean air temperature, water-table level and drought indices were calculated from data given by the nearest meteorological station to each trap. The periodicity of population peaks and outbreaks, synchrony between fluctuation patterns in different localities and regions, and long-term trends in patterns of defoliators and other moths were studied by the methods of time series analysis. The spatial changes of abundances probably caused by climate variation were also investigated. It was found that the drought periods showed significant influences on the fluctuation pattern of moths.

02-070

THE OCCURRENCE OF *PANONYCHUS CITRI* (McGREGOR) (ACARI: TETRANYCHIDAE) IN NORTHERN ITALY: DISTRIBUTION, HOST RANGE AND PHENOLOGY

C. Duso

Istituto di Entomologia agraria, Università di Padova, Italy

In the late 80ties, symptoms linked to spider mite feeding were observed on ornamental plants, in particular *Prunus laurocerasus*, in Padova (Veneto, Northern Italy). Surprisingly, the symptoms were caused by *Panonychus citri* (McGregor) a tetranychid well-known as one of the major pests of *Citrus* in the world and widespread in the Mediterranean area. Previously, *P. citri* had been recorded only in Southern Italy, especially on *Citrus* species.

Laboratory studies on a population collected on *P. laurocerasus* in Padova showed different rates of developmental success on *Prunus laurocerasus*, *Citrus aurantium*, *Poncirus trifoliata* e *Pyrus serotina*. In particular, the highest values were reached on *P. laurocerasus*. Developmental times were also shorter on *P. laurocerasus* than on *P. trifoliata* e *C. aurantium*. Fecundity was higher on *P. serotina* and intermediate on *P. laurocerasus*.

Field observations, carried out in different sites and on *P. laurocerasus*, show that *P. citri* populations reach higher densities in early summer. Some weeks later population densities dramatically decrease. The impact of predators does not appear important. A new population increase in late summer is seldom observed.

02-069

INVASION OF NORTH AMERICAN FORESTS BY INTRODUCED PESTS: ECOLOGICAL PROCESSES

R.M. Muzika, A. M. Liebhold, Northeastern Forest Experiment Station, USDA Forest Service, Morgantown, WV USA

The number of introduced organisms in North America has increased markedly in the past several decades. The effects of introduced organisms on ecosystem properties appear to be at least as great as the effects of climate change and air pollution. Among these, insects and diseases have had known detrimental effects and generally appear more dramatic in agricultural or intensively managed areas than forested lands. The effects of introduced insects and diseases are complex and likely as severe as the effects of plants, but they may be more subtle, and hence more insidious. The extent to which introduced organisms influence functional relationships and ecosystem - wide processes is poorly understood. The nature of ecological impacts of an introduced organism depends upon its ecological role, and exotic organisms occupy a variety of ecological niches. Furthermore, insect and disease pest problems are not simply remedied, and can create biological and management dilemmas. Among the examples to illustrate the potential and actual effects of introduced insects and diseases are: gypsy moth (*Lymantria dispar.*), balsam woolly aphid (*Adelges piceae*), pitch canker disease (*Fusarium moniliforme*), and white pine blister rust (*Cronartium ribicola*).

02-071

EFFECTS OF CLIMATIC VARIABLES ON LONG-TERM FLUCTUATION PATTERNS OF GROUND BEETLES (COL., CARABIDAE) IN HUNGARY

F. Kádár, F. Szentkirályi

Department of Zoology, Plant Protection Research Institute of the Hungarian Academy of Sciences, Budapest, Hungary

The carabid beetles are important predatory insects in agricultural habitats. Their population size expresses frequently stronger fluctuations. These results produced by using pitfall trapping which is the best method to follow the changes in carabid population dynamics. However there are only few long-term fluctuation pattern analysis of ground beetles.

We used long-term data sets for analysis of flight activity fluctuation patterns of some important carabid species based on collections of Hungarian agricultural light trap network. We selected three carabid species for the analyses which showed the highest total yearly individuals captured in the most light trap sites. These species were the *Clivina fossor*, *Harpalus froelichii*, and *H. griseus*. The populations of *C. fossor* prefer mainly wet habitats, but the two *Harpalus* ground beetles are rather xerophilous spp.

The aims of this study were to show any influence of climate variations on the long-term fluctuation patterns of carabids. The yearly total number of specimens captured by local light traps were applied for the analysis. In the time series analysis we investigated the carabid data set characteristics (periodicity, trends, synchrony between sites and between species) and the effects of climate variables (air temperature, amount of precipitation, drought indices, weather front frequency) on the flight activity fluctuation patterns.

02-072

THE CENTERS OF HOVERFLIES (DIPTERA: SYRPHIDAE) DIVERSITY IN SERBIA

A. Vujić, S. Šimić, P. Radišić, S. Radenković

Institute of Biology, University of Novi Sad, Novi Sad, Yugoslavia

The Syrphidae, known as hoverflies or flowerflies are an attractive and heterogeneous group of day flying insects and include many distinctive species. These two-winged flies are characterized by diversity, adaptability and a high degree of adaptational radiation.

Investigations of syrphids fauna in Serbia, shown the considerable species-richness of this region. There has been established an account of about 400 hoverflies species until now. Extremely complex processes in formation of the fauna on the Balkan Peninsula during past geological periods resulted in appearance of many different faunistic elements in Serbia. Therefore, in the same region there is a mixture of the species that originated from distinct and distant biogeographical areas.

This paper points out some of important centers of hoverflies diversity in Serbia. The western and eastern parts of Serbia differ in types of refuges and relics due to geographical position (different in climatic, geomorphologic and historical-geological aspects). In the east, limestone gorges (i.g., gorge of Lazareva reka, Sićevačka, Jelašnička) and canyon valleys, since the Tertiary up to the present time, are the most typical refuges of the Tertiary relics and endemorelics. Their specific features provide the possibilities of preservation and living of the zoogeographically different types of species. Especially, the gorges with west-eastern direction offer a shelter for many species with different ecological requirements. To the contrary, the high mountains on the west (e.g., Kopaonik) are richer in Dinaric endemic and northeuropean and centraleuropean boreo-montane species. The third area, mountain Šarplanina, that lie in the south, contains preglacial relicts, besides Dinaric endemic.

02-074

BIOLOGY AND WORLDWIDE DISTRIBUTION OF SOME WEEVIL GENERA (COLEOPTERA: CURCULIONOIDEA)

J. Rheinheimer

Merziger Str. 24, D 67063 Ludwigshafen, Germany

Some weevil groups (Coleoptera: Curculionidae) do occupy a narrow range only while others are widely distributed throughout all continents. Biology and host plant preferences of the latter group have been analysed and compared with the distribution patterns.

Recent research indicates, that some genera of the old family Apionidae are occurring in Europe and/or North America as well as in South Africa or Australia on host plants of the same plant family. Examples are *Taenapion* (Urticaceae), *Pseudapion* (Malvaceae) and the *Ixapion*-complex (Rutaceae). In addition some genera of Apionidae with a wide distribution are restricted to Fabaceae.

Different observations have been made in some groups of Curculionidae. In the Rhynchaeninae the genus *Rhynchophus* lives on Rosaceae in Europe. In Australia the host plants belong to the Mimosaceae. A similar pattern is shown by the related genus *Rhynchaenus* occurring on Fagaceae, Myricaceae, Salicaceae, Caprifoliaceae and Betulaceae in Europe and North America. In South Africa several species have been found on *Grewia* (Tiliaceae) and on Rubiaceae. In India it is known to damage *Mangifera* trees (Anacardiaceae), and it lives on *Brachychiton* (Sterculiaceae) in Australia. Remarkably this group is distributed in all continents except South America.

This may indicate that at the time of the separation of the continents some genera of Apionidae had already been adapted to their present host plant families and have remained relatively constant morphologically and ecologically since.

On the contrary the Rhynchaeninae appear to be quite similar morphologically today, but must have undergone considerable ecological evolution since the continents have separated. Possibly this group started to radiate across the ancient supercontinent after separation of South America only.

02-073

ARE BRAZILIAN SPECIES OF *ELYTROSphaera* (COL., CHRYSOMELIDAE), AN APTEROUS GENUS, THREATENED OF EXTINCTION?J. Vasconcellos-Neto, P. Jolivet¹

Laboratório de Interações Insetos/Plantas. Departamento de Zoologia, IB, Universidade Estadual de Campinas. CP 6109. CEP 13083-970. Campinas-SP, Brazil. - 1 67 Bd Soult, 75012, Paris, France.

The Neotropical genus *Elytrosphaera* is composed of several apterous montane species. The subgenus *Elytrosphaera* s. str. occurs at altitudes varying from 800 to 2000 m mainly on the Brazilian plateau (8 species), and Yungas del Palmar, Bolivia (one species). The Brazilian species are threatened with extinction due their life style and their distribution over areas with high human density with agricultural and industrial activities. These species are poorly known and only the biology of *E. xanthopyga* has been described by P. Jolivet. The adult and larvae feed on leaves of the shrub *Adenostema brasilianum* (Asteraceae) in primary forest at an altitude of 900 to 1000 m at Viçosa-MG.

Data from museum specimens collected during the last 60 years show that adult beetles appear only at the end of spring and beginning of summer, and apparently diapause in the soil during the rest of the year. Since these species are apterous they do not recolonized forest fragments. Fire and deforestation are the mainly factors limiting *Elytrosphaera* populations.

ZOOGEOGRAPHY AND BIODIVERSITY OF SYRPHIDAE (DIPTERA) IN EASTERN AFRICA.

M. De Meyer¹, A.E. Whittington², L. De Bruyn³ & E. Vanden Berghe¹¹ National Museums of Kenya, Nairobi, Kenya; ² National Museums of Scotland, Edinburgh, Scotland; ³ University of Antwerp (RUCA), Antwerpen, Belgium

The zoogeography and biodiversity of the hoverfly fauna (Diptera, Syrphidae) of eastern Africa (i.e. Kenya, Tanzania, and Uganda) is hereby discussed based on a database compiled at the National Museums of Kenya and linked with a GIS system. The database contains approximately 3000 block records and is based on literature references and on collection specimens from National Museums of Kenya (Nairobi, Kenya), Natural History Museum (London, UK.), Natal Museum (Pietermaritzburg, South Africa) and Koninklijk Museum voor Midden-Afrika (Tervuren, Belgium). Total number of syrphids in the region is 219 with 171 found in Kenya, 123 in Tanzania and 127 in Uganda. Of these, 70 species are found in all three countries while respectively 46, 27 and 14 are reported for Kenya, Tanzania and Uganda only. The bias towards Kenya is mainly the result of more intensive sampling efforts in this country. Kenya shows a higher overlap with either Tanzania or Uganda than the latter two have with each other. This was looked at as a reflection of the more extensive border line shared by Kenya with the other two countries. There are 44 species endemic to East Africa, 4 of these occur exclusively in Uganda, 10 in Kenya and 11 in Tanzania. Looking at the specimens/country size ratio, all countries have a more or less similar rate of endemism. Analysing the occurrence of Syrphidae at a generic level, most genera show the same tendencies as the ones observed for the family as a whole, with a few exceptions. Although coverage of the region is patchy and the number of block records is limited, some general zoogeographical and ecological tendencies can be observed which are briefly discussed.

02-076

ANALYSIS OF THE BIODIVERSITY OF SYRPHIDAE (DIPTERA) IN DRY TROPICAL RAINFOREST IN KENYA.

M. De Meyer¹ & L. De Bruyn²

¹National Museums of Kenya, Nairobi, Kenya; ²University of Antwerp (RUCA), Antwerpen, Belgium

Between 1994 and 1995 Syrphidae were collected at Kakamega rainforest. This forest is situated in the western province of Kenya, and once formed part of a large tropical rain forest belt stretching all the way to Zaire. However, Kakamega forest has been isolated from the main forest for several decennia and forms the easternmost relict of dry guineo-congolian rain forest. It is also the only relict of this vegetation type in Kenya and most of its fauna and flora is unique to the country. Syrphidae were collected mainly by hand sweeping during six successive visits at roughly two monthly intervals. In total, 65 species were found of which 11 were new to Kenya. An additional 9 species were reported from Kakamega forest in literature or presented in older collections. After comparison with other syrphid data for eastern Africa (i.e. Uganda, Kenya and Tanzania) 18 species seem to be unique within Kenya. Of these, 12 show a zoogeographical link with Ugandan forests and represent relicts of the guineo-congolian forest belt, being mainly distributed in Central African and tropical West African countries. Species composition between different habitats within the forest (largely undisturbed and disturbed forest, glades, cleared bushland) and with areas outside the forest are presented with the forest areas showing the largest diversity. The fauna outside the forest boundaries is relatively very poor compared to the species composition within the forest area. Seasonal differences in occurrence were also recorded.

02-078

BEETLES LYCIDAE (COLEOPTERA) OF UKRAINE.

P. Sheshurak

Today 8 species of Lycidae are registered in Ukraine: *Lopherus rubens* Gyll., *Dictyoptera aurora* Hbst., *D. superba* Motsch., *D. nigrorubra* DeG., *Platycis minuta* F., *P. cosnardi* Chev., *Xylobanellus erythroptera* Bdi., *Lygistopterus sanguineus* L. From them only *L. sanguineus* is general, the rest of them are rare. *P. cosnardi* is known only from the Carpathians, the rest can be met in Wooded District; *L. sanguineus* penetrates into the Steppe Zone along the valley of the rivers and can be met in the Crimea too.

All species keep wooded biotopes with enough humidity. In hernigov region the larvas of *L. sanguineus* were noticed in rotten wood. Imagos were met most of all feeding on Umbelliferae or on the trunks of dead trees (*Betula*, *Populus tremula*). *D. aurora* was found on the rotten stump, *P. minuta* were found feeding on Umbelliferae. Beetles are active in day time. Females laid eggs in the crack of the bark or in the hole of ways of various xylophagous.

02-077

AREA TYPES OF HIGH ALTITUDE WEEVIL SPECIES FROM YUGOSLAVIA (COLEOPTERA - CURCULIONIDAE)

G. Mesaros

Institute for Biological Research, Department of Evolutionary Biology, Belgrade, Yugoslavia

The ecosystems above the timber line at the high mountains of Balkan peninsula are inhabited with a rich fauna of weevils composed by the species from genera *Otiorhynchus*, *Tropiphorus*, *Alophus*, *Plinthus* and *Trachyploeus*.

Two types of weevil communities could be recognise in the high altitude zone on mountains in Yugoslavia: communities at a top of the mountains and around the snow spots at elevations above 2000 m; and communities distributed in different types of mountain meadows and pastures in the wide range of 1700-2100 m above sea level.

The insects from the first group are subnival species and the distribution of the appropriate species is restricted only on the one particular mountain or at geologically and historically very close mountains (southern dinarian, prokletian or scardic mountains). Between different mountain complexes there is a noticeable zoogeographical vicariance. The insects from high mountain meadows have two different types of areas. Most of them are distributed on all mountains from dinaric or scardic mountain complexes, respectively. Sometimes intraspecific variation between populations from different mountains within the same complexes can be observed. The most important factors for their evolutionary divergence were the Pleistocene climatic fluctuations. On the other hand, some species are with wide distribution, sometimes extrazonally but, always in open habitats with degraded vegetation. These species are most probably prediluvian origin and relicts of xerotherm (oromediterranean) communities that were destroyed during glatiations.

02-079

UPDATING OF THE CHECK-LIST OF APHIDS (HOM. APHIDIDAE) IN BELGIUM

J.M. Nieto-Nafria, G. Latteur¹, M.P. Mier-Durante

Departamento de Biología Animal, Universidad de León, Leon, Spain - ¹ Station de Zoologie Appliquée, Gembloux, Belgium

The only complete check-list of aphids (Hom. Aphididae, sensu Pemaudière and Stroyan) in Belgium was published in 1906. In 1956 a new partial check-list was published (related to the Aphididae s.s.). Owing to the changes which have occurred in nomenclature of the aphids, neither of these two check-lists are useful nowadays for non-specialized entomologists and also various dispersed citations have been recorded.

We have revised all the publications on aphids which refer to Belgium and we have prepared a new bibliographical check-list. The known Belgian aphid fauna is made up of 234 species, almost half of them have not been cited since 1945 and many are known from citations prior to 1920. Moreover, only four species have been cited for the first time in this country since 1961.

New aphid fauna studies in Belgium are needed because 1) due to the environmental changes it is very possible that many species cited are not now to be found there, and 2) many other species (known in the north of France, north of Germany, The Netherlands and even Denmark) should populate Belgium.

02-080

ANOTHER NORTH AMERICAN APHID (HOM. APHIDIDAE) ON EUROPE

M.P. Mier-Durante, J.M. Nieto-Nafría

Departamento de Biología Animal, Universidad de León, León, Spain

News on the presence of insects far from their natural areas of distribution is becoming more and more frequent due to their introduction by humans.

We have captured another North American species: *Myzocallis* (*Lineomyzocallis*) *occulta* Richards for the first time in Europe, limited until now to a few small areas of Canada and the United States and living on *Quercus rubra* which in Europe is grown in parks and gardens.

The subgenus *Lineomyzocallis* is nearctic. This new introduced species was found in a city park in Pontevedra (Galicia, north west Spain) on red oak and mixed with *M. (L.) walshii*, which is already known in France and we have previously cited in that Spanish city.

02-081

TERRESTRIAL INSECTS OF THE PÁLAVA BIOSPHERE RESERVE OF UNESCO

R. Rozkošný, J. Vaňhara

Department of Zoology and Ecology, Faculty of Science, Masaryk University, Brno, Czech Republic - Institute of Forest Ecology, Faculty of Forestry and Wood Technology, Mendel University of Agriculture and Forestry, Brno, Czech Republic

The Pálava Biosphere Reserve lies in the southern part of the historical territory of Moravia (Czech Republic). The planned extended concept of the Pálava B.R. will cover about 250 sq.km. Three information sources were utilized for compiling the prodrome of insects (prepared in the framework of the prodrome of macroinvertebrates): (1) results of several monitoring programmes implemented in the study area during the past 25 years, (2) data from several dozens of institutional and private collections, (3) records published in about 200 faunistic, ecological and taxonomic papers. In cooperation with more than 40 specialists the comments to all orders of terrestrial (free-living) insects are given.

The research project has resulted in the registration of 9,439 insect species (i.e. about 40 % of the insect fauna known in the Czech Republic). Just from the study area, 99 valid species have been described. Special attention was paid to the stenoeic species confined to xerothermic stands or floodplain forests as widely receding ecosystems. Many species of Pontic, Mediterranean and Pannonian origin reach the northern limit of their range in the Pálava B.R. Data from some long-term monitoring programmes confirmed the extinction of about 20 taxa in the area, additional more than 270 taxa are suggested to be included in different categories (critically endangered, endangered and vulnerable) of species conservation. The condensed information may be used for completing the natural characteristics of the study area, for launching programmes monitoring the selected insect assemblages or taxocoenoses, for objectively assessing the risks connected with human activities in this area and, at the same time, for improving the protection of valuable ecosystems and rare species.

02-082

BIODIVERSITY AND BIOGEOGRAPHY OF CARABIDAE AND TENEBRIONIDAE (COL.) ON THE SOUTH AEGEAN ISLAND ARC

A. Trichas¹ & A. Legakis²¹ Natural History Museum of Crete, Univ. of Crete, Irakleion, Greece² Zoological Museum, Dept. of Biology, Univ. of Athens, Athens, Greece

The south Aegean island arc is well known for its richness in endemic plant and animal taxa. In fact, it is an island landbridge connecting the coast of mainland Greece with the southern shores of Asia Minor, with Crete, Rodos, Karpathos and Kythira being the largest islands with high mountains (1200 to 2500 m except Kythira), many gorges and some permanent water. There are no large plains throughout the islands, except the Mesara plain in central Crete. Due to the varied surface relief and its geographic position, the whole area has diverse climatic conditions, ranging from continental (high mountains of Crete) to mediterranean desert climate (southeast Crete, Kasos, satellite islands etc.).

In order to correlate events from the geological past related to the complex history of the Aegean islands with the present situation and to explain the present faunal composition and origin of the same area, we studied for the past ten years the ground beetle faunas of the south Aegean islands through extensive collecting on the major islands of the arc.

The biodiversity of Carabidae and Tenebrionidae is presented using faunal element and species distribution analysis. The degree of endemism at the specific as well as subspecific level is also discussed. Comparisons between islands revealed extensive faunal dissimilarities, showing more than one possible ways of formation of the south Aegean beetle fauna. The influence of the surrounding areas is also considered.

Cluster analysis using presence-absence data matrices of both families, revealed interesting patterns concerning the zoogeography of the area. We obtained similar results using faunal element categories rather than species in percentage matrices. Three island groups with high degree of internal similarity resulted from the analysis. One group consists of the islands on the west side of Crete (Kythira and Antikythira), a second group was formed by the islands on the east side (Kasos, Karpathos and Rodos) while Crete and its surrounding satellite islands formed the third group. The whole area shows no faunal evidence of common geological evolution after the Pliocene.

02-083

DROSOPHILIDS AND OTHER INSECTS ASSOCIATED WITH PARAHANCORNIA AMAPA FRUITS DISPERSED ON THE AMAZONIAN FOREST FLOOR.

M. Martins Museu Paraense Emílio Goeldi /CNPq/ MCT. Belém Pará Brasil

This community, showed a high species richness but the community structure was marked by a low equitability among its components. *Drosophila* was the predominant group among the insects. A gradual dominance alteration was detected in the *Drosophila* group, with *D. malerkotliana* becoming progressively more abundant all along the period. *D. malerkotliana* was mainly associated with the fruits at the beginning of fermentation and presented a high concentration of only one yeast species, *Kloeckera apiculata*. *Drosophila malerkotliana* was consistently the first species to occupy the fruits on day before the others. The other *Drosophila* species presented a broader diversification in using yeasts and they used fruits in later decomposition stages. All *Drosophila* distribution was affected by the weight of the fruits, pointing to a higher concentration of flies on heavier fruits and to a total exclusion in those fruits below the median weight. Life strategies indicated *D. malerkotliana* and the subgroup species *willstoni* as being fast species and *D. sturtevantii* appeared to be a slow species. *D. sturtevantii* stood out in relation to oviposition patterns, development period and longevity. The increasing success of *D. malerkotliana* observed during these three years of studies corresponded with the recent expansion of the species in the Amazon region and in the Neotropical region as a whole. This and other studies indicate a combination between the species characteristics and modifications occurred in their habitat, favouring their expansion and the decrease in their guild diversity.

02-084

CATERPILLAR SEASONALITY IN CENTRAL BRAZILIAN CERRADO

H. C. Morais¹, I. R. Diniz², D. M. Silva³Instituto de Biologia, Universidade de Brasília, 70910-900, Brasília, DF, Brasil. ^{1,3} Departamento de Ecologia, ² Departamento de Zoologia.

The work was carried out in three 1 ha block of cerrado *sensu stricto* near Brasília during five years. The climate is highly seasonal with a marked wet (October-March) and dry (April-September) seasons. A total of 10,800 host plants were examined and on 15% we encountered externally feeding caterpillars. They were reared under laboratory conditions. A monthly abundance for all species of Lepidoptera was compiled and all data of pupation was registered. The caterpillar abundance was variable. It increased sharply in May and remained high until July, at which time declined sharply until the lowest abundance in early-wet season (October) and then increased slightly between December and January. The lowest caterpillar abundance coincided with the driest period, during which the host plant are leafless or with senescent leaves (August-September), but also when the majority of cerrado plants put out their new leaf crop (September-October). The caterpillar community appears to be severely depressed due to the stress of the late-dry season, food shortage and, the onset of heavy rains. Also the small size of caterpillars, after the onset of rains make them inconspicuous in censuses. Two hypothesis were proposed to explain the highest abundance at the early dry season: to avoid consumption of the well defended new leaves and to escape from predators. We successfully reared 247 lepidopteran species (31 families) of which 86.6% occurred at low density (less than 12 times). The duration of the pupal stage and its variance increased in the end of the wet season. They tended to be shorter at the beginning of the dry season, increasing during the dry season and sharply decreasing between the end of dry season and the start of wet season. Some caterpillar species are present on food plants throughout the year (*Isognatus caricae* - Sphingidae) whereas others occur at certain times, either in dry (*Megalopyge albicollis* - Megalopygidae) or wet season (*Siderone marthesia* - Nymphalidae). Emphasis in this work was on the detection of pattern which is a necessary precursor to other studies.

02-086

ENRICHING OUR KNOWLEDGE ON THE GREEK APHIDOFAUNA BY SETTING UP A NETWORK OF ROTHAMSTED TYPE SUCTION TRAPS

I.A. Tsitsipis¹, D. Lykouressis¹, N. Katis², V. F. Eastop³, J. Gargalianou, A. Papapanayotou², S. Liapi, M. Alexandri and C. Chalkia¹

Faculty of Crop and Animal Production, University of Thessalia, Volos, Greece - 1 Faculty of Crop Production, Agricultural University of Athens, Greece - 2 Faculty of Crop Production, Aristotle University of Thessaloniki, Greece - 3 The Natural History Museum, London, U.K.

The knowledge of the Greek aphidofauna until 1992 was very poorly known, since there had not been any systematic study performed. Until then 140 different aphid species had been recorded. In 1992 a network of four "Rothamsted", 12.2m high, suction traps were set up in Thessaloniki, Velesino-Thessalia, Kopais-Voiotia and Koroivos-Ilia respectively. During the following four consecutive years a large number of alates were caught in the traps. In total, more than 175 taxa, not recorded previously in Greece, were caught. Most of them were identified to the species level. In Thessaloniki 107 different taxa were collected, in Velesino 139 and in Kopais 145. The trap in Koroivos was not in operation during the above period. For all the species detailed weekly, and in some cases daily, captures have been kept. Although the highest numbers of alatae were observed during the summer, the highest species variation was found in the spring. The collected data contribute considerably to the knowledge of the aphid-transmitted virus epidemiology in economic crops.

02-085

THE SPECIES *ADELPHOPHYLUS* ON THE BALKAN PENINSULA

Ljiljana Protić

Natural History Museum, Belgrade

The starting point for our research was Wagner's claim that the genus *Adelphophylus* is represented by 1 species - *A. balcanicus* Korm. (Wagner, 1975.). The study of the morphological, ecological and biogeographical characteristics has lead us to the conclusion that there exist 2 different species: *Adelphophylus balcanicus* and *Adelphophylus breviceps*. Firstly, there is the difference in the morphological structure of the genital armature of the males. *A. balcanicus* has "handshaped armature" on vesica, whereas *A. breviceps* does not. Secondly, the populations of *A. balcanicus* inhabit *Verbascum* species only, whereas *A. breviceps* has a wider ecological valency and is found from the zone of deciduous forests to the zone of mountainous habitats (meadows and pastures). Thirdly, on the territory of the former Yugoslavia, in Macedonia, the populations of *A. balcanicus* are concentrated in the Northwest, and the populations of *A. breviceps* in the East. Although their respective ranges are separated, they sometimes overlap, which further points to the claim that there are two different species of the genus *Adelphophylus*.

02-087

VERTICAL DISTRIBUTION OF THE SAWFLIES (HYMENOPTERA: SYMPHYTA) OF VELEBIT AND BIOKOVO MOUNTAINS

S. Leiner, F. Perović

Croatian Natural History Museum, Department of Zoology, 10000 Zagreb, Croatia

Total of 101 taxa of sawflies have been registered on Mt. Biokovo and 220 on Mt. Velebit, 127 for its southern region and 180 for its northern region. Forty percent of species are present on both regions. Only 23 species are common for Biokovo and Velebit.

Distribution of species are connected to vegetational belts: 6 on Biokovo, 7 on North Velebit, and 9 on South Velebit. The lowest vegetational belt of Biokovo (0 to 300 m) is *Orno-Quercetum ilicis* having 20 species of sawflies. *Quercus-Carpinetum orientalis* is the lowest belt of North Velebit with 35 species, while *Paliuretum adriaticum* of South Velebit has only 11 species. With sawflies richest belts are located on Biokovo and North Velebit between 900 and 1350 m above sea level. The *Pinetum mugii illyricum* belt has only three characteristic sawfly species on South and three on North Velebit.

Families Pamphiliidae, Siricidae, Orussidae, and Cephidae were not registered for Biokovo; while for Velebit we have no data only for the family Xielidae.

02-088

BIODIVERSITY OF NEW ZEALAND BEETLES (INSECTA, COLEOPTERA)

J. Klimaszewski and D. Gleeson,

Manaaki Whenua - Landcare Research, Private Bag 92170, Auckland, New Zealand.

The beetles are the largest order of organisms, comprising over 350 000 described species worldwide. Approximately 5235 species are described for New Zealand, including 313 introduced. They belong to 82 families in two suborders, Adephaga and Polyphaga. The suborders Archostemata and Myxophaga, although present in Australia, are not represented. Of the 82 New Zealand families, none is endemic, and four contain only introduced species (Archeocrypticidae, Gyrinidae, Lycidae, and Trogidae). Eleven families are represented by more than 100 described species. The numbers of Curculionidae, Staphylinidae, Carabidae, and Scydmaenidae in proportion to the total number of beetle species in New Zealand are similar to the proportions in Australia. However, Colydiidae and Scirtidae are particularly diversified, and are relatively better represented in New Zealand than in Australia. The New Zealand beetle fauna is distinguished by the absence of many major lineages, a high level of endemism, which in many groups is over 90% at the specific level and over 43% at the generic level (e.g., Staphylinidae), and the radiation of many groups of genera and species. The origins of New Zealand's beetle fauna are still poorly understood. They are likely to be varied, including Gondwana elements and elements which arrived here by short and long-distance dispersal recently and in the remote past. Phylogenetic studies within and outside New Zealand, are needed in order to establish the origins of the fauna. The size of the New Zealand beetle fauna is consistent with species number/land area relationships in other areas around the world, including the United Kingdom.

02-090

CURRENT STUDIES ON THE WHITEFLY FAUNA OF THE MEDITERRANEAN BASIN (HOMOPTERA ALEYRODIDAE)

C. Rapisarda¹, D. Mifsud², J.H. Martin³

1 Istituto di Entomologia agraria, Università degli Studi, Catania, Italy - 2 Department of Biology, University of Malta, Msida, Malta - 3 Department of Entomology, The Natural History Museum, London, UK

Since the publication of a catalogue of the world's whitefly, in 1978, there have been several local faunistic reviews of whiteflies within the Mediterranean area, and these have often been accompanied by descriptions of new species. Twelve new species have been described from the area during this time. Work is now progressing on the whitefly fauna of the whole of the Mediterranean Basin, comprising over fifty species, and a revision is under preparation, presenting also a complete identification key. In the present note, general biological, ecological, systematic and distributional data will be presented, including host-plant records and known geographical range. The zoogeography of the group will also be discussed.

02-089

NEW DATA ABOUT THE CARABOIDEA FROM EXTREMADURA (SPAIN)

J. P. Zaballos, I. Ruiz-Tapiador¹

Dptº Biología Animal I. Entomología. Facultad de Biología. U.C.M. Ciudad Universitaria s/n 28040 Madrid. ESPAÑA

1 Dptº Ciencia y Tecnología Aplicada. E.U.I.T. Agrícola. U.P.M. Ciudad Universitaria s/n. 28040 Madrid. ESPAÑA

The Natural Region of Extremadura is a place that have a good conservation situation, and included some protected areas like the National Park of Monfragüe.

Extremadura has an extension of 41602 Km², and altitudes are between 200 and 2401 m, it is located in the South West of Spain. The preserving situation is special, one of the most important ecosystem is named "Dehesa", and is the result of the rinsing of the old Mediterranean forest, this is a very good example about the equilibrium between the nature preservation and the economic improvement.

The knowledge of the entomological fauna is very poor, particularly about Caraboidea, only exist partial data (Uhagón, 1876; Gayubo et al, 1987), with the help of a project of Spanish government (DGICYT PB88-0377-C02-00 and PB92-0121), a complete study about the Caraboidea of this area has been done.

The attainment of data was made in the period 1990-1991, during all seasons of the year and with different sampling techniques.

In the present communication, we have a preliminary check-list of the Caraboidea from Extremadura, and we do special mention about recently described species like: *Typhlocharis gomezi* Zaballos, 1991, *T. pacensis* Zaballos y Jeanne, 1987; *T. belenae* Zaballos, 1983; *T. jeannei* Zaballos, 1989, *T. carpetanus* Zaballos, 1989; *T. portilloi* Zaballos, 1991; *T. wrasei* Zaballos y Farinós, 1995; *T. hiekei* Zaballos y Farinós, 1995; *Geocharis iborensis* Zaballos, 1990; *Geocharis julianae* Zaballos, 1989 or about changes in the distribution of other, like *Callistus lunatus* Fabricius, 1775; *Acupalpus ibericus* Jaeger, 1988 and others.

02-091

A ZOOGEOGRAPHICAL ANALYSIS OF THE SICILIAN SCALE INSECT FAUNA (HOMOPTERA COCCOIDEA)

A. Russo, G. Mazzeo, S. Longo

Istituto di Entomologia agraria, Università di Catania, Italy

Zoogeographical studies on the Sicilian scale insects fauna have been carried out, whose interest derives from the geographic position of the Island (in the middle of Mediterranean basin) and its paleogeographic and paleoclimatic origin. The approximately 160 species of Homoptera Coccoidea, listed up to now in Sicily, mostly belong to the families Diaspididae (45.91% of the total number), Pseudococcidae (23.27%) and Coccidae (12.58%). Scarcely represented are the families Eriococcidae (5.03%), Asterolecanidae, Kermesidae, Margarodidae (each one 3.14% of total number), Acleridae, Cerococcidae, Cryptococcidae, Micrococcidae, Ortheziidae, Phoenicococcidae (complexively 3.79% of total number). According to the distributional patterns recently elaborated by Italian researchers and currently used in faunistic studies of Western Palaearctic area, these *taxa* should be separated in: cosmopolitan or subcosmopolitan elements (42.14 % of total number), distributional patterns with wide distribution in Palaearctic region (25.18%), distributional patterns with wide distribution in Europe (4.40 %), distributional patterns with wide distribution in Mediterranean basin (19.50%) and elements with restricted distribution area (6.91). The Sicilian fauna, in its complex, appears very rich of Palaearctic and Mediterranean typical elements, while it is poor of African ones. The high percentage of cosmopolitan or subcosmopolitan elements shows how the anthropic activities are one of the most important factors of passive diffusion for Homoptera Coccoidea. Lacking zoogeographic studies on scale insects fauna on close areas, it is very difficult to understand if species with a restricted distribution pattern have to be considered endemic element or more probably they are also present, but unrecorded, in close areas.

02-092

THE BIOGEOGRAPHY OF BUPRESTIDAE (COLEOPTERA) OF THE NON-TROPICAL REGIONS OF THE SOUTHERN HEMISPHERE

B. Levey
Department of Zoology, National Museums & Galleries of Wales, Cathays Park, Cardiff, CF1 3NP, U.K.

The distribution of selected groups of Buprestidae of the Southern Hemisphere is discussed. A variety of distribution patterns are exhibited by groups in the non-tropical regions of the Southern Hemisphere. Some of these distribution patterns might be interpreted as indicating a gondwanic origin for these groups, but other groups have non-tropical bihemispheric distributions suggesting that other interpretations are possible.

02-094

PRELIMINARY DATA ON THE MACROLEPIDOPTERA OF THE NATURAL RESERVE OF VENDICARI (SIRACUSA, S. E. SICILY) AND FIRST RECORD FOR SICILY OF *LEUCANIA PALESTINAE* STAUDINGER, 1897 (LEPIDOPTERA: NOCTUIDAE)

P. Parenzan
Istituto di Entomologia agraria, Università di Palermo, Italy
First collections of Lepidoptera have been done of the Natural Reserve of Vendicari (Siracusa, S. E. Sicily).
As a whole, 41 species have been identified and among them, the followings 3 were new for the Sicilian fauna: *Cyclophora annulata* (Schulze, 1775) (Geometridae), *Leucania joannisi* Boursin & Rungs, 1952 (Noctuidae), *Leucania palestinae* Stdgr. (Noctuidae). The last one is also new for continental Italy.
Other interesting species collected are the followings: *Chlorissa faustinata* Milliére, 1868, *Scopula emutaria* (Hübner, (1809)), *Casilda consecraria* (Staudinger, 1871), *Platysenta viscosa* (Freyer, 1831), *Discestra sociabilis* (de Graslin, 1850).

02-093

THE COLEOPTERA OF THE MARSH OF FUCECCHIO, TUSCANY (ITALY)

A. Bordoni
Centro di Ricerca, Documentazione e Promozione del Padule di Fucecchio, Castelmartini e Museo Zoologico "La Specola", sezione del Museo di Storia Naturale dell'Università di Firenze, Italy.
The Marsh of Fucecchio is one of the largest non-littoral marshes in Europe (1800 hectares). This marsh has an exceptional botanical importance representing a relict of the "tundra" in the middle of the Mediterranean area, with a rich group of boreal and arctic-alpine entities, survived after the last post-glacial period.
Some fragmentary informations were available on the fauna of Coleoptera of this habitat, and only recently a volume on this argument has been published (Bordoni, 1995), reporting the results of a thirty year field study. A total of 999 species of Coleoptera (71 families) have been identified and 851 (29 families) have been considered deeply; of these 236 are helobious, living in ten Coleopteran associations in some ecological zones (*Lemna*, *Phragmites*, *Carex elata*, *Quercus coenosis*). The Fucecchio marsh offers one of the last refuges for a remarkable number of species of great ecological and biogeographical interest, with a prevalently northern distribution. Some species, typical in the Central Europe marshlands, are reported for the first time south of the Appennines. The research reveals that Fucecchio hosts a much richer coleopteran fauna, both in number of species and individuals, that any other such habitat studied in Italy. It also shows that some species extremely rare are abundant in this biotope and points out the presence of an high percentage of European elements s.l. with a prevalently northern distribution and a fair number of entities of Siberian origin. As many as 23% of the helobious species find their southern limit in Tuscany and, in some cases, in the Fucecchio marsh itself; their distribution is obviously dotted since it is restricted to wetlands in the sense of refuge.
These results contributed to underline the great importance of the Fucecchio marsh as an high biodiversity habitat in Italy, that deserves urgent attention and protection.

02-095

BIOGEOGRAPHY AND BIODIVERSITY OF MALAGASY MAYFLIES (EPHEMEROPTERA): THE GENUS *CHEIROGENESIA* (PALINGENIIDAE)

M. SARTORI¹, J.-M. ELOUARD² & L. RUFFIEUX¹
¹ Museum of Zoology, Lausanne, Switzerland
² ORSTOM/LRSAE, Antananarivo, Madagascar

Although belonging to the Afrotropical Realm, Madagascar occupies an peculiar position since some of its zoological and botanical elements undoubtedly present more affinities with the Oriental Realm. As for other groups, Malagasy mayflies (Ephemeroptera) exhibit a high proportion of endemism. *Cheirogenesia* is an endemic genus and up to now considered as monospecific. Intensive field samples over the last four years let us to discover several new species.
In this work, biogeographical affinities of this genus with other Palingeniidae are quoted and an Oriental origin for this family is proposed.
Factors involved in the distribution of *Cheirogenesia* are presented. As this genus clearly colonizes two types of habitats, ecological and phylogenetic relationships among actually known species are also discussed.

02-096

FAUNAL RECORDS ON COLEOPTERA BYRRHIDAE CAUGHT WITH PITFALL TRAPS IN THE WESTERN JULIAN ALPS (NORTH-EASTERN ITALY)

R.A. Fabbri, G. Governatori¹Museo civico di Storia naturale, Ferrara, Italy - ¹ Dipartimento di Biologia applicata alla Difesa delle Piante, Università di Udine, Italy

The presence of Coleoptera Byrrhidae was monitored on Mount Canin and Mount Montasio (western Julian Alps, north-eastern Italy) by using pitfall traps (Barber traps) from May 1989 to April 1991. The traps contained a saturated solution of sodium chloride in vinegar (7% acetic acid) which was replaced every three weeks. The following environments were investigated: two alpine grasslands (1580m and 2155m above sea level), two thickets of *Pinus mugo* Turra (1595m and 1775m), two willow groves (1220m and 1770m), two beech woods (840m and 1400m), two mixed spruce-beech woods (1010m and 1250m), two ski slope meadows (1170m and 1210m), an arid stony meadow (1010m) and the edges of a dry rill (1170m). In all the sites the rocks were calcareous or dolomitic.

A total of 14 species, out of 42 known in Italy and out of 18 known in the western Julian Alps, were collected: *Simplocaria semistriata* (F.), *S. carpathica* Hampe, *Morychus aeneus* (F.), *Pedilophorus auratus* (Duftschmid), *Cytilus sericeus* (Forster), *Byrrhus fasciatus* (Forster), *B. pilula* (L.), *B. pustulatus* (Forster), *B. luniger* Germar, *B. signatus* Panzer, *B. gigas* F., *Curimus erinaceus* (Duftschmid), *Curimopsis paleata* (Erichson), *C. carniolica* (Ganglbauer). Nine of these species are more or less widely distributed throughout Europe; the remaining are Palearctic or Holarctic. *Byrrhus luniger* is recorded for the first time in eastern Italy and *Curimopsis carniolica*, an endemic species of the eastern Alps and the Illyrian area, occurred for the second time in Italy, about one century after the first finding. *Pedilophorus auratus* was the dominant taxon in the samples and also the most eurytopic species. Most individuals and species were collected from June to July. Pitfall traps can be used in studies on the bryophagous beetle fauna, in the same way as they are used for the ground beetle fauna.

02-098

CHANGES IN CARABID'S FAUNA OF BELARUS' FOR THE LAST 150 YEARS

O.R. Alexandrovitch

Kafedra of Zoology, Belarus' State Pedagogical University, Minsk, Belarus

In second half of last century at the eastern part of Belarus such common now species as *Carabus nemoralis* Mull. and *Amara majuscula* Chd. were absent. European species *C. nemoralis* the first time was found in vicinity of Vitebsk in 1940, and after 1960 it was the common at all terrain. Approximately at the same time sibiric species *A. majuscula* moved to Belarus from east. For the last 10 years european species *Nebria brevicollis* (F.) migrates from west to the Central Belarus.

The drainage of Polesie's peat-bogs was the possible reason of moving to the nord such stepp species as *Calosoma denticolle* Gebl., *C. investigator* (Ill.), *Calathus halensis* (Schall.), *Poecilus punctulatus* (Schall.), *Amara tricuspidata* Dej., *Harpalus servus* (Duft.), *H. pumilus* Sturm, *H. froelichii* Sturm, *Anisodactylus signatus* (Pz.), *Microlestes maurus* (Sturm).

Known from the past *Callisthenes reticulatus* (F.) and *Lebia cyanocephala* (L.) not found from the beginning of present century.

02-097

BIOGEOGRAPHY OF MIRIDAE OF CATALONIA (SPAIN) (INSECTA: HETEROPTERA)

M. Goula, J. Ribes¹

Departament de Biologia Animal (Unitat d'Artròpodes), Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain - ¹ Museu de Zoologia de Barcelona, Barcelona, Spain

In the area of Catalonia (Spain), 370 species of Heteroptera Miridae have been recorded. As a first part of the work, a taxonomic check-list was already published. In the present communication, a biogeographical analysis of this check-list is given in a series of maps. They show how the different biogeographical categories are represented all over the area of study, taking into account the geomorphological usually recognised in it.

02-099

MONTHLY DISTRIBUTION OF ICHNEUMONIDAE (HYMENOPTERA) IN CENTRAL TAMAULIPAS, MEXICO

J. Coronado-Blanco, E. Ruíz Cancino
FACULTAD DE AGRONOMIA, UNIVERSIDAD AUTONOMA DE TAMAULIPAS, CD. VICTORIA, TAM., MEXICO.

Ichneumonids are very important to control some Lepidoptera and other pests. For that reason, it is important to know when are more abundant. With nets, biweekly and diurnally, we collected Ichneumonidae in 12 month period in a locality of Central Tamaulipas, in a Oak forest.

718 specimens in 15 subfamilies from 77 genera were obtained. Cryptinae (216) specimens, Ichneumoninae (137) and Pimplinae (133) were the subfamilies more collected. Only Cryptinae and Ichneumoninae were collected all the year.

None of the genera were obtained all months. *Coelichneumon* and *Setanta* were present in 10 months, *Ischnus*, *Baltazaria*, *Hoplismenus*, *Dusona*, *Eudeleboea* and *Netelia* in 9, and *Pimpla* and *Neotheronia* in 8. However, *Pimpla* (7.2%), *Eudeleboea* (6.1%) and *Enicospilus* (5.5%) were the commoner genera. In March, 21.3% of individuals was collected, followed by October (12%) and December (10.4%) On the other hand, 43 genera (56%) were represented only by 8.4% of individuals, with only 1-3 per genus.

02-100

PIMPLIFORM ICHNEUMONIDAE (HYMENOPTERA) IN THE COLLECTION OF HYMENOPTERA, FACULTY OF AGRONOMY-UAT, MEXICO
J.M. Coronado Blanco, E. Ruíz Cancino
Facultad de Agronomía, Universidad Autónoma de Tamaulipas, Cd. Victoria, Tam. México.

Since 1979, Hymenoptera has been collected in order to form the best collection in northern México, including Ichneumonidae. México is specially rich-species, 535 spp. were recorder by Townes & Townes 30 years ago.

In the State of Tamaulipas, ichneumonids has been collected with nets. This report only includes pimpliforms. Three subfamilies 11 genera and 16 species are recorded. The more abundant genera is Neotheronia (Pimplinae) with 145 specimens (56.64%).

The other species collected are Epirhyssa mexicana Cresson (Rhyssinae), Ganodes sp. and Ganodes n. sp. (Poemeniinae), Acrotaphus sp., Pimpla sanguinipes Cresson, Pimpla punicipes Cresson, Pimpla caerulea Brullé, Pimpla sp., Scambus sp., Calliephialtes sp., Iseropus sp. and Dolichomitus sp. (Pimplinae), which were determined by Dr. C. C. Porter.

November was the month with more specimens followed by March and February. More diversity were found in more humid localities, and in November, too.

02-102

A NEW APPROACH TO THE OBJECTIVE ZOOGEOGRAPHICAL REGIONALIZATION

G.S.Medvedev, A.L.Lobanov, G.M.Abdurakhmanov, Sh.I.Ismailov
Zoological Institute, Russian Academy of Sciences, St.Petersburg
199034, Russia

An new computer-aided method of the objective zoogeographical subdivision of the territories based on the data of the discrete locality faunas is suggested. The techniques constituting the new method are demonstrated on an artificial example with the known final result. The new method is tested on the data on tenebrionid beetles distribution in the Caucasus and Mongolia. This method enables using the primary data on the records of definite taxa in the discrete localities accumulated in the computer databases.

- The new method is based on the following theses:
1. Cluster analysis, being used for regionalization, is used not for faunas of plots subjectively chosen by an investigator but for objectively registered faunas of discrete localities.
 2. The comparison of faunas of discrete localities is preceded by the detailed computer analysis of available information when it is possible to select the reliable and significant data.
 3. The re-count of matrix of locality similarity and clusters at every step of clusterization is made not on the basis of calculation of their average similarity, but on the basis of uniting the faunas of blended localities or clusters, and new calculation of their similarity.
 4. Cluster analysis accounts not only the similarity of locality faunas, but also physical distance between these localities, calculated from their exact geographical co-ordinates. It allows to smooth accidental similarity of remote localities, which often appears because of unadequate knowledge of their faunas and of accidental coincidence.
 5. The process of cluster analysis of locality faunas will go both in computer memory (as a transformations of similarity matrices), and on display (as a dynamic transformation of differently coloured sectors on the map). It gives the investigator a unique chance to control visually every step of clustering process of localities and to get, when necessary, any additional information on each step.

02-101

BIODIVERSITY AND BIOGEOGRAPHY OF THE ECUADOR MANTIDS (INSECTA MANTODEA)

F. Lombardo
Dipartimento di Biologia Animale Università di Catania, Italy.

The author has compiled a list of 50 species of Mantids present in Ecuador by reviewing the data reported in the literature and adding his personal observations which are still being processed. Analysis of their geographical distribution shows that 38% of the species presents a wide distribution, 42% is present a limited area, comprehending only Perú and Colombia, and that 20% is endemic. The abundance of species and especially the discrete number of endemisms are related to paleoclimatic events that have favoured the formation of new species in this place.

02-103

PRIORITY AREAS ANALYSIS: A THAILAND EXAMPLE USING OWLS (AVES: STRIGIDAE), HAWKMOTHS (LEPIDOPTERA: SPHINGIDAE) AND TIGER BEETLES (COLEOPTERA: CICINDELIDAE)

I.J. Kitching
Biogeography & Conservation Laboratory, Department of Entomology, The Natural History Museum, London, Great Britain
Setting priorities in biodiversity conservation requires that explicit, efficient and appropriate methods are developed and made available to conservation managers. The principle of complementarity is fundamental to the most efficient of these methods. Given a goal of a single representation of each taxon, complementarity analysis of data sets of owls, hawkmoths and tiger beetles in Thailand yields near-minimum sets of 6, 14 and 34 areas respectively. The consensus of these sets comprises 48 areas. However, when the data are combined into a single data set, complementarity analysis gives a more efficient solution of 46 areas. Over 90% of the owls, hawkmoths and tiger beetles are already represented as a minimum of one population within the current protected areas network of Thailand. However, an additional 18 areas are still required for complete representation.

02-104

FIRST RECORD FROM ITALY OF *MONARDIA OBSOLETA* EDWARDS
(DIPTERA: CECIDOMYIIDAE LESTREMINAE)

L. Santini, A. Lucchi.

Dipartimento di Coltivazione e Difesa delle Specie Legnose, Sezione Entomologia agraria, Università degli Studi di Pisa, Italy.

During the early spring of 1995, a number of mature larvae of *Monardia obsoleta* Edwards have been found on young fruiting bodies of the annual many-coloured polypore *Trametes* (= *Coryolus*) *versicolor* (L.: Fr.) Pilat, growing on decaying broadleaf tree branches fallen to the ground, in different wooded areas of the litoral Tuscany. At the end of April 1995 pupae and adults of the species have been obtained from this material.

The main taxonomic features of *M. obsoleta*, first recorded from Italy, are described and illustrated by drawings, light stereomicroscope photographs and SEM micrographs.

The orange elongated larva has a small weakly sclerotized head and relatively short antennae. The sternal spatula anteriorly bears three sclerotized teeth.

Adults show a typical eye-bridge and 3-segmented palpi. Male presents a wing length of about 1.3 mm, antennae 14-segmented and styles of the hypopygium with a short terminal spine. Female has a wing-length of about 1.8 mm, antennae 17-segmented and two roundish sclerotized spermathecae.

02-106

THE *BOMBINI* OF THE NATIONAL PARK OF SIBILLINI MOUNTAINS (CENTRAL ITALY). (HYMENOPTERA, APIDAE: *BOMBUS* LATR. AND *PSITHYRUS* LEP.)

M. Quaranta, G. Ricciardelli D'Albore¹

Istituto sperimentale per la Zoologia Agraria, sezione operativa periferica di Apicoltura, Roma, Italy - ¹ Istituto di Entomologia Agraria, Università degli studi di Perugia, Perugia, Italy

The Authors have studied the faunistic composition of bumblebees (*Bombus* Latr.) and their social parasites (*Psithyrus* Lep.) in the National Park of Sibillini Mountains (central Apennines) on the base of nearly 2500 specimen caught in 3 years.

The park spread over about 70000 ha, in the territory of Umbria and Marche regions, within an altitude range of 400 - 2476 meters.

15 species of bumblebees have been found, with 17 subspecies, and 5 species of *Psithyrus*, with 7 subspecies.

One species, *Bombus mucidus* Gerst., already known in central Italy, has been found in this zone for the first time.

Data about the species' corology and the faunistic composition related with the altitudinal vegetation zones, and observations on the flora foraged, are provided.

02-105

MEASURING BIODIVERSITY OF ANTS (HYMENOPTERA: FORMICIDAE)

K. Ogata

Institute of Tropical Agriculture, Kyushu University, Fukuoka 812-81, Japan

The purpose of this study is to show effectiveness of a time unit sampling methods of ants. In measuring biodiversity of ants in a local fauna, in particularly of the tropical regions, a surveyor faces various practical impediments. Among them, time would be one of the major factors affecting quality of a survey. Under such condition, a time unit sampling (TUS) would be an effective way. This is a method collecting as many ant species as possible during 30-min. visual manual search on the surface of the ground, under stones or wood bark, and around the base of tree trunks.

In Okinawa Island (28°N x 126°E), Japan, 41 species belonging to 28 genera of 4 subfamilies were collected by TUS from 12 sampling plots, which corresponds to 60 % of the total number of species or less. The ratio of eurychoric species is higher in open land.

In addition, the results of the surveys in other areas of Japan, Bangladesh, SE Asia, and Panama are presented. The utility and limits of the sampling are also discussed.

02-107

MYCETOPHILOIDS (DIPTERA, MYCETOPHILOIDEA) OF THE "CHERNEVAJA TAIGA" OF THE SOUTH OF WESTERN SIBERIA

G.P. Ostroverkhova

Biology Faculty, Tomsk State University, Tomsk, Russia

"Chernevaja taiga" is the relict dark coniferous forest (Subnemorosa) with the fir, the fir spruce, the cedar pine and the admixture of the aspen. For the first time 94 species of Mycetophiloids for the middle mountain taiga of the western main slope of Kuznetsk Alatau mountains are described. These species are included in 24 genera of 6 families: *Bolitophilidae* - 7 species (*Bolitophila* - 6, *Messala* - 1); *Ditomiyidae* - 1 (*Symmerus*); *Keroplastidae* - 1 (*Keroplastus*); *Macroceridae* - 2 (*Macrocera*); *Sciophilidae* - 15 (*Mycomyia* - 8, *Polylepta* - 1, *Neurotelia* - 1, *Platinia* - 1, *Leia* - 2, *Monoclona* - 1, *Acnemia* - 1); *Mycetophilidae* - 68 (*Anatella* - 1, *Exechia* - 11, *Rhymosia* - 4, *Brachypeza* - 1, *Allodia* - 5, *Brevicornu* - 1, *Trichonta* - 8, *Phronia* - 7, *Mycetophila* - 26, *Sceptonia* - 1, *Epicypa* - 2, *Delopsis* - 1).

Mycetophiloids of the coniferous middle-mountain forest are the inhabitants of aspen-fir, pine-fir and fir biotopes. They represent both the specific ecological group of the dark coniferous forest and the mountain-taiga faunistic complex. The zoogeographical elements of this complex include the following species: cosmopolitic species - 2 (2%), holarctic - 14 (15%), transpalearctic - 18 (20%), eurosiberian - 16 (18%), conditionally siberian - 43 (45%). The conditionally siberian species are known only on the territory of Western Siberia and their area is studied insufficiently. In addition, 5 new species (*Leia* - 1, *Monoclona* - 1, *Exechia* - 1, *Brachypeza* - 1, *Mycetophila* - 1) are described as the possible paleoendemics - the relicts of the glacial epoch.

02-108

INSECTS IN THE CANOPY OF A TEMPERATE RAINFOREST: THE CARMANAH PROJECT**R.A. RING, N.N. WINCHESTER**Biology Department, University of Victoria,
Victoria, B.C. V8W 2Y2 Canada

The Upper Carmanah Valley on S-W Vancouver Island lies within the Coastal Western Hemlock biogeoclimatic zone and forms a small part of an extensive Coastal, Temperate Rainforest (CTRF) biome on the west coast of British Columbia. A canopy research station has been established in old-growth Sitka spruce and this species has been studied intensively with respect to canopy and forest floor insect/arthropod diversity since 1991. More than 1.2 million insects and other arthropods (mainly spiders and mites) have been collected using a variety of trapping techniques. Results show that perhaps the most interesting habitat contained in the canopy is that provided by the 4-28 cm deep moss mats that are formed on a well developed soil layer on the upper surfaces of large branches. These mats are primarily composed of four moss species which are also abundant on the forest floor. Collembola (springtails) and Acari (mites) dominate this canopy soil/litter habitat, an observation that has not been documented in any previous canopy study. Our preliminary list of mites indicates that significant differences exist at the species level between canopy and forest floor and that several of the canopy species are new to science. The same trend applies to the Collembola. An informative view of canopy arthropods can also be gained by placing them in feeding guilds. The guild structure in our study is dominated by photophagous and predator/parasitoid species. The high incidence of a predatory/parasitoid guild also supports the results of other studies which indicate that herbivory in mature, structurally-complex forests is relatively low.

02-110

SPECIES OF GENUS *EUTRICHOCAMPA* (DIPLURA, CAMPODEIDAE) ON BALKAN PENINSULA**Bela Blesić**Institute of Biology, Faculty of Sciences, University of
Kragujevac, Yugoslavia

According to data from literature the genus *Eutrichocampa* Silvestri, 1902 is not widely distributed in Europe. However, the fauna of the family *Campodeidae*, and especially of the genus *Eutrichocampa*, is insufficiently investigated in our country. The first date about the occurrence of this genus in Yugoslavia is given by Condé (1947), on the basis of data recorded Condé, he also mentioned presence in Yugoslavia. Condé (1947) discovered *Eutrichocampa* in the West Serbia, in the vicinity of Novi Pazar.

From 13 species known in the world, in Europe 6 species belonging to the genus *Eutrichocampa* have been described up to date. *Eutrichocampa remyi* Condé, 1947 was found on the Balkan peninsula in Serbia (Yugoslavia) and Greece Macedonia. *E. hispanica* Silvestri, 1932 is distributed in Spain. Only on Rodos (insula) is recorded *E. aegea* Silvestri, 1933. *E. helvetica* Wygodzinsky, 1941 is distributed in Switzerland. *E. (Chaocampa) collina* described by Ionescu (1955). Her subspecies is described as *ithacesia* Condé (1984) from Ithaca (Greece). *E. thamagadensis* Condé, 1948 is distributed in Corsica - France. On Balkan up to date are distributed 2 species.

02-109

Bees genus *Hylaeus* Fabricius, 1793 of Azerbaijan (Hymenoptera, Apoidea, Colletidae)

H.A. Aliev

Department of arachnology of Institute of Zoology, Azerbaijan Academy of Sciences, Baku, Azerbaijan Republic

Bees genus *Hylaeus* Fabricius, 1793 are presented in Azerbaijan by 36 species. European-Caucasian (13), Mediterranean (10) and West-Palearctic (8) species are broadly presented. There are less species presented in Palearctic-only 3, and East-Mediterranean and endemics of Caucasus and the ones with limited natural habitat are presented only by 1 species.

02-111

CHALCIDIDAE (HYMENOPTERA) OF CENTRAL ASIA: BIODIVERSITY AND HOSTS**S.N. Myartseva, V.A. Trjapitzin¹**Institute of Zoology, Academy of Sciences of Turkmenistan, Ashgabat, Turkmenistan -
¹ Zoological Institute, Russian Academy of Sciences, Saint-Peterburg, Russia

The total list of centralasian wasps of the family Chalcididae includes 82 species from 20 genera. Half of these species are distributed in Central Asia only. 14 species from them are discovered in Tadzhikistan only, 8 - in Turkmenistan and 7 - in Iran only. Palearctic distribution have 32 species, 8 species pass the limit of Palearctic: 7 - into Indomalayan zoogeographical province and one comes across Holarctic. Thus, fauna of chalcidid wasps consists of many centralasian endemics and has considerable diversity of species.

As hosts of parasitic wasps were registered 89 species of insects. The generality of wasps are primary and secondary internal parasitoids of insects from orders Lepidoptera, Diptera, Coleoptera, some Hymenoptera and Neuroptera. Most practical significance in region have some representatives of large genus *Brachymeria*.

02-112

STAPHYLINIDAE (COLEOPTERA) FAUNA OF THE CRIMEA AND ITS ORIGIN

V.I.Gusarov

Department of Entomology, Faculty of Biology and Soil Sciences, St.Petersburg State University, St.Petersburg, Russia

Reconstruction of the historical development of the Crimean fauna based on the geographical distribution of the species from different habitats has been done. In Pleistocene glaciations most of thermophilous Pliocene species including endemics became extinct in the Crimea (modern endemism level - 2%). Few of them survived in the Southern Crimean Coast refuges. The latter were not available for forest species from Russian plain, the steppe barrier constantly existing. In the glaciations boreal species penetrated the Crimea, but most of them disappeared in Holocene (they survived in the Caucasus). Hygrophilous species came to the Crimea at the beginning of each interglaciation, when it was already warm, the Black Sea was fresh and its level was lower than it is now.

02-114

SPECIES DIVERSITY OF BUTTERFLY COMMUNITIES IN A COUNTRYSIDE COPPICE IN OSAKA, JAPAN

Minoru Ishii

Entomological Laboratory, College of Agriculture, Osaka Prefecture University, Sakai, Osaka 593, Japan

Transect counts of butterflies were made along a 1.3 km path through a countryside coppice dominated by *Quercus serrata*, Japanese cypress plantations, and farmlands with paddy fields in Osaka, central Japan in 1994. A total of 730 individuals belonging to 45 species was observed during 15 counts from April to November. Both species diversity and density for whole transect ($H' = 4.6$ and 37 individuals/km) were as high as those in other coppices in Osaka. The species diversity was the highest in the coppice edge, the next highest in the farmland, and the lowest in the coppice interior and plantation. The density of butterflies was the highest in the farmland, the next highest in the coppice edge and cutover, and the lowest in the coppice interior and plantation. Although numbers of species and individuals were large from May to June in most environments, they became smaller in the height of summer in the coppice edge, cutover, and farmland, where butterflies increased again in October. On the other hand, butterflies were relatively abundant in summer but decreased rapidly in autumn in the coppice interior and plantation. The results suggest that the mosaic of different environment in the countryside coppice is important in maintenance of the diversity and abundance of butterflies.

02-113

BIODIVERSITY OF DOLICHOPODID FLIES (DIPTERA) IN TROPICAL FORESTS OF AFRICA AND INDIAN OCEAN ISLANDS

I. Ya. Grichanov

All-Russian Plant Protection Institute, St.-Petersburg-Pushkin Russia

The known Afrotropical and Indian Ocean islands fauna of the family Dolichopodidae is relatively small, with about 500 species ("Catalogue of the Diptera of the Afrotropical Region", 1980). But it is quite possible that the real number of species is more than 1000.

The main aim was to determine the biodiversity and taxonomic status of rare or undescribed dolichopodid species from Tropical Africa, Mascarenes and other Indian Ocean islands.

During the last year the work was concentrated on studying the rich collection of 4000 undetermined species from the Natural History Museum (London). Most of the specimens, provided with geographical and ecological labels, were collected from tropical forests in Uganda, Kenya and Mauritius. The collection probably includes from 100 to 200 undescribed dolichopodid species.

About 500 specimens were identified during the first year of research, belonging to 38 identified species from 10 genera. 2 genera, 23 species and females of 2 known species were first described. The most interesting records are as follows:

Argyrochlamis impudicus Lamb - Seychelles, Mauritius, Sri Lanka, Chagos Is.; *Bickelia subparallela* sp.n. - Chagos Archipelago, Seychelles; *Chrysosoma leucopogon* Wiedemann - Tanzania, Kenya (!), Mauritius, Reunion, Rodriguez, Oriental Region, Australia, Oceania. *Mascaromyia libravitertex* Lamb - Seychelles, Mauritius (!), Chagos Archipelago (!).

02-115

ICHNEUMONIDAE (HYMENOPTERA) FROM THE STATE OF TAMAULIPAS, MEXICO

E. Ruíz Cancino

Facultad de Agronomía, Universidad Autónoma de Tamaulipas, Cd. Victoria, Tam., México.

Thirty years ago, Townes & Townes recorded 171 genera and 535 species of Ichneumonidae from México, including only 4 genera and 4 species from Tamaulipas. In 1988, Ruíz found 243 genera from our country, based in field collections of this important family. This present report includes recent work done in Tamaulipas, in northeastern México.

Since 1981, ichneumonids have been obtained mainly with aerial and sweeping nets and some with Malaise and UV light traps. Diurnal collectings have been done in Oak forests, pine forest, cloud forest and low deciduous forest. Determinations were done by the author, and some by C.C. Porter and J. Luhman. The specimens are deposited in the Collection of Hymenoptera, at this Faculty.

168 genera from 23 subfamilies are known, it means almost the Townes number for all the country. Cryptinae and Ichneumoninae are the best represented, with 37 and 33 species, respectively. *Netelia*, *Enicospilus*, *Eiphosoma*, *Compsocryptus*, *Pimpla*, *Dusona* and *Neotheronia* were the most collected genera. Nine new records were obtained.

02-116

SPECTRAL SEQUENCE OF THE FOODPLANTS OF THE FAMILY LYCAENIDAE AND RELATING FAMILIES OF BUTTERFLIES AND THE APPERARANCE AND THE GENEALOGY OF DIVERSITY OF THE RELATING ANGIOSPERMS.

Kawai, R.
Kanazawa Institute of Technology.

The family LYCAENIDAE has 2 large groups of butterflies: Thecline-group and Polyommertine-group. The investigation of the spectrum of foodplants of each group shows that these 2 spectra crosses at a point X near to the family Hamamelidaceae. This group X includes the families of Angiosperms with very primitive sructures such as the families belonging to the orders CELASTRALES, RHAMNALES and SAXIFRAGALES etc., all of which are seemed to be remaining in various stage of evolution, seeing at the present time-point.

It seems that this group X of primitive Angiosperms has a "multistrata structure" according as the "biological time" of the individual Angiosperms constituting this group. Though this group X arose as the foodplants of LYCAENIDAE, it has an intimate relation to the foodplants of the other families of butterflies RIODINIDAE, NYMPHALIDAE etc..

On the other hand, in the family PAPILIONIDAE, there are very old butterfly-species, called the "living fossils", which are distributed along an Equator of old times approximately 650my B.P.. The foodplants of these "living fossils" are extremely limited: the most part of them is Aristolochiaceae and some parts are Crassulaceae and Papaveraceae. Considering upon these facts, the group X is closely related to these families of foodplants of the family PAPILIONIDAE. Except for these "living fossils", because the family PAPILIONIDAE is also connected to the family PIERIDAE, the above group of Angiosperms X is also naturally connected to the spectrum of the foodplants of the family PIERIDAE.

As a consequence of these considerations, we have come to a conclusion that the group of Angiosperms X is a group of Angiosperms which is originated in the principal part of the GONDOWANALAND and diversified to other places according as the law of the evolution and differentiation.

02-118

PATTERNS OF DIVERSITY IN COLLEMBOLA FROM MONTANE WET FORESTS OF HAWAII

D. Foote, K. Magnacca
Hawaii National Park Field Station, Pacific Islands Science Center, National Biological Service, HI USA

Species diversity and community structure of springtails are compared for mid-elevation rainforests on the islands of Molokai and Hawaii. Elevation, substrate age and the history of feral pig activity all significantly influence Collembolan community composition. Historical surveys of Collembola in Hawaii are reviewed and the utility of using springtails as biological indicators of changes in Hawaiian ecosystems is discussed.

02-117

A PRELIMINARY REPORT ON THE STUDY OF THE BUTTERFLIES IN THE ZHONGTIAO MOUNTAIN

Ren-jun Fan¹, Xing-ke Yang¹, Peng-jie Han², Wen-shu Li³
Institute of Plant Protection, Shanxi Academy of Agricultural Sciences, Taiyuan, Shanxi, China. -1 Institute of Zoology, Academia Sinica, Beijing, China. -2 Institute of Plant Protection, Shanxi Academy of Agricultural Sciences, Taiyuan, Shanxi, China. -3 Institute of Zoology, Academia Sinica, Beijing, China.

Zhongtiao Mountain is situated in the southeastern Shanxi Near Mt. Huanggutun, there are about 667 ha primeval forest. It is rich in natural resources. Some scientific surveys on plants and vertebrates had been previously carried out in this region. But, the gap is in the insect fauna. So, an investigation on the butterflies have been conducted. 67 species belonging to 7 families, have been obtained. The fauna is composed of Palaearctic and Oriental elements with Palaearctic elements dominant. The geographical distribution of Palaearctic faunal elements is in the pattern of northern China. The Oriental elements are composed of elements from southwest China and middle China. The intruding channel of the elements may be through two ways: the first is from Qinling mountains, and the second is from niddle China along the junctures of Shanxi, Hubei and Henan Provinces into Zhongtiao mountain. Therefore, this fact can help us infer that the bound of Oricntal region in Shanxi Province is Zhongtiao mountain.

HAWAIIAN INSECTS AND EQUILIBRIUM ISLAND BIOGEOGRAPHY

P. WIGFULL, S.B. PECK, G. NISHIDA(1); Carleton University, Ottawa, Canada; and (1) Bishop Museum, Honolulu, Hawaii.

A complete species inventory of the known insect fauna of the Hawaiian Islands has been published (Nishida 1994). We have used it to analyze island biogeographic patterns by regression analyses. Many analyses yielded strikingly significant results lending support to several theories of island biogeography. Extremely significant results were found for regressions of area and elevation against total number of insect species per island. These results probably reflect the higher heterogeneity/diversity of habitats on larger islands, which in turn may provide resistance to disruption and resulting extinction. An analysis of the number of insect genera against island area further supports this ecological explanation, by reducing the effect of speciation on the regression. Analyses of age and number of insect species are confounded by the reduced area and number of habitats present on the older islands. Thus, it is shown that island area is a better predictor of species diversity than is island age. Regression of the number of single-island endemic species as well as the species:genus ratio against island age, area, and elevation suggest that speciation is fostered by habitat diversity and opportunity for speciation as well as by complex topography and the resulting physical isolating mechanisms. These results do not suggest that rates of speciation are necessarily "explosive" for younger islands, but rather that younger islands harbour more products of speciation due to habitat heterogeneity/diversity and relaxed competition.

02-120

DIVERSITY OF NECTAR RESOURCE UTILISATION IN MALAGASY SPHINGID COMMUNITIES (LEPIDOPTERA: SPHINGIDAE)

R. U. Walthier & L. T. Wasserthal

Institut für Zoologie I, Universität Erlangen-Nürnberg, Staudtstrasse 5, D-91058 Erlangen, Germany

Due to the species-dependent differences in proboscis length, sphingid moths are regarded as highly specialised flower visitors of various plant species. However, little is known about the entire spectrum of flowers visited by certain sphingid species.

Hawkmoth communities of Madagascar show larger ranges of proboscis length (maximum 1.1-26.5 cm) than those of other paleotropical regions. To clarify whether flowers are visited by hawkmoths in a more generalistic or selective way, the whole pollenloads of approximately 2000 captured individuals were examined by means of light- and scanning electron microscopy. In addition, morphometrical and phenological data were evaluated, and the abundance of flowers at the study sites was estimated.

The position of the anthers within all flowers examined, allowed adherence of pollen to all species of sphingid moths occurring, regardless to their proboscis length. According to the composition of their individual pollenload most sphingid moth species turned out to be generalist feeders, both on sphingophilous and on non specialised flowers. Sphingid species varied in the number of visited plant species, as well as in flower constancy.

Individuals of long tongued species carried pollen of a larger number of plant species, while those with short proboscis tended to be more selective than expected. This supports our hypothesis stating that an extreme length of the proboscis may not be caused by flower morphology, but rather by feeding while hovering.

Our research was financially supported by the Deutsche Forschungsgemeinschaft (Wa 258/4).

02-121

PRESENT KNOWLEDGE ON THE ITALIAN PSYLLIDS (HOMOPTERA PSYLLOIDEA)

C. Conci¹, C. Rapisarda²

1 Museo civico di Storia naturale, Milano, Italy - 2 Istituto di Entomologia agraria, Università degli Studi, Catania, Italy

Taxonomy, biology and ecology of Homoptera Psylloidea have been largely investigated in Italy during the last fifteen years and a wide review on this topic is presently in press, whose data are summarized here. As a whole, 199 species have been totally recorded, thus confirming the Italian one as the richest fauna presently known in Europe. A lower biodiversity appeared in central and southern Italian regions, compared to the northern ones. An almost uniform diffusion all over the national territory has been shown by 21 out of the 199 species, while, on the contrary, a highly restricted or even punctiform distribution has been evidenced by a group of 24 species; 11 species have been exclusively collected in Italy, up to now. As to biological aspects, polyvoltinism showed to be fairly rare among this insect group, since only less than 20 species perform more than two yearly generations; on the contrary, the greatest part of Italian psyllids (about 110 species) are monovoltine. A selective host plant preference has been evidenced: psyllids live in Italy only on 41 (with Leguminosae, Compositae, Salicaceae and Rosaceae being the most preferred ones) among the nearly 141 families and a bit more than 110 out of the nearly 1,090 genera of Angiosperms recorded in this country.

02-122

ARTHROPOD DIVERSITY IN FOUR MOUNTAIN FORESTS OF THE ITALIAN ALPS

P. Bonavita, C. Chemini, P. Ambrosi¹, S. Minerbi², C. Salvadori¹

Centro di Ecologia Alpina, Viote del Monte Bondone, Trento, Italy -

1 Istituto Agrario di S. Michele all'Adige, U. O. Foreste, Trento, Italy -

2 Ispettorato per le Foreste, Provincia Autonoma di Bolzano, Italy

Arthropod diversity was studied in 4 sampling sites in the Provinces of Trento and Bolzano (Italian Alps) within the activities carried out in the ICP Integrated Monitoring programme.

Two sites were deciduous forests at low altitude (550-700 m), and two sites were Norway spruce and cembra pine forests close to the timber line (1720-1820 m).

Inventory of arthropod species was carried out by pitfall traps, light traps and other sampling methods, collecting both soil and plant dwelling taxa. More than 2,000 arthropod species were identified, belonging to Opiliones, Araneae, Collembola, Carabidae, Staphylinidae, Cerambycidae, Elateroidea, Scarabaeoidea, Heteroptera, Lepidoptera, and other small taxa.

Number, composition and relative abundances of species in the assemblages have been analyzed and correlated to environmental parameters and historical processes. Diversity was higher in the low altitude sites. Deciduous forests accounted for 78% of the total species diversity, whereas coniferous forests only 34%. A strong turnover of species occurred between the two types of forests, and significant variations in species composition were recorded also within forest types, with similar variation patterns in deciduous and coniferous stands. Taxa with greater dispersal power showed a lower faunal turnover. The biodiversity patterns reflect the complex biogeographical history and the ecological heterogeneity of the area.

02-123

QUANTIFYING BIODIVERSITY. MULTIPLE USES OF A NEW DATABASE. THE EXAMPLE OF ACARI (ARACHNIDA).

F. Athias-Binche

Laboratoire Arago UA CNRS 117/Université Paris VI, Département d'Ecologie Evolutive, BP 44, F-66651 BANYULS SUR MER CEDEX, France email: athias@arago.univ-perp.fr

Biodiversity gives rise to considerable interests. As it covers many different levels, from intra-specific genetic diversity to functional diversity along food chains, or specific diversity within the biosphere, the quantification of so various aspects needs mathematical tools. The size relations indicate that small species are generally more abundant than larger ones. Therefore, mites being certainly the smallest known arthropods, one could predict that they should be more numerous than insects. Such hypothesis demands also an appropriate means of quantification. Furthermore, a quantification of ecological traits of mites allows also to put in concrete form their often written, but not yet computerized, extraordinary ecological diversity.

The present contribution describes a new database and suggests some applications. The data consists of 7 columns of taxa and features: body length, egg length, clutch size, ecology (habitats, parasitism or phoresy) and sexuality (arrhenotoky or thelytoky). The updated file comprises 7892 species (3020 anactinotrichids and 4872 actinotrichids). The 23 anactinotrichid superfamilies accommodate 76 families and 454 genera. Actinotrichida assemble 77 superfamilies, 239 families and 1310 genera.

The most immediate use of the data consists simply in considering only taxonomic items. This is illustrated by a preliminary example of statistical biosystematics. If we consider each taxonomic category as so many samples, it becomes possible to treat mathematically pure systematic data by affecting the number 1 to each item. Then, one can calculate classic statistics and usual tests. The variation coefficient expresses here the homogeneity of the distribution of species within groups.

The database permits diverse kinds of study of ecological diversity, which may be mathematically expressed by a diversity index. This allows rapid comparative analysis between groups.

A third main use of the database concerns body sizes. First, the range, the difference between the highest and lowest measurement, gives an estimation of heterogeneity, of a group. The classical statistics allow to compare different taxa. With its 79 μm , the tiny *Cochlodius minimus* (Tarsonemida) is certainly the smallest known adult Acari. Graphs of sizes indicate an important character: all the histograms present a negatively skewed distributions, the mode being always inferior to the mean. This asymmetry reflects a remarkable evolutive trend towards miniaturization. This tendency stumbles against an inevitable wall, the lowest limit of size and organization for an adult arthropod; this buffer should be situated around a body length of 70 μm .

From the few examples proposed here, one can conceive numerous other interesting studies. As the present database is largely open, future users will certainly find new subjects of researches and theories.

02-124

BIODIVERSITY OF PSEUDOSCORPIONS IN YUGOSLAVIA: THE ORIGIN AND GENESIS OF ENDEMICS AND RELICTS

Ćurčić, B. P. M., R. N. Dimitrijević, S. E. Makarov, L. R. Lučić

Institute of Zoology, Faculty of Science (Biology), University of Belgrade, Studentski Trg 16, 11000 Belgrade, Yugoslavia.

The primordial pseudoscorpion stock had colonised the Proto-Balkans (including Serbia and Montenegro) at the beginning of its existence. Subsequently, it gave birth to a number of phyletic series. Such stem forms inhabited the leaf-litter and humus during or even before the Tertiary. Evidently, the ancient epigean fauna was subjected to local destruction due to unfavourable changes of climate, and the lack of migration or possibilities to shelter.

Biogeographically, the Mediterranean and the Pannonian and Ponto-Caspian regions are the two main refuge zones of European pseudoscorpions. The first region was a refuge to a more thermophilous fauna, the second to the Tertiary elements of Central Europe, which migrated southwards due to climatic and other changes. The Dinaric and Carpatho-Balkan Karst are inhabited by the great number of endemic and relict pseudoscorpions of different lineages - from the Gondwanan to the Aegean. These species and genera represent the last vestiges of an old fauna, which found their shelters in different domains of the vast refugial zone of the Balkan Peninsula. Such forms were later subjected to the divergent differentiation in numerous epigean and underground habitats (the "evolutionary explosion" of species in the so-called "Adriatic angle").

02-126

DIVERSIFICATION OF MILLIPEDES IN YUGOSLAVIA: BIOGEOGRAPHIC IMPLICATIONS

Ćurčić, B. P. M., R. N. Dimitrijević, S. E. Makarov, L. R. Lučić

Institute of Zoology, Faculty of Science (Biology), University of Belgrade, Studentski Trg 16, 11000 Belgrade, Yugoslavia.

Out of 98 species of Yugoslav diplopods, classified into 41 genera and 18 families, 17 species and 11 subspecies (or 28.57%) are endemic, either to Serbia and/or Montenegro or to both regions. Of these, 14 taxa are troglobites, while others inhabit epigean habitats.

The pattern of the relictual and autochthonous fauna of endemic and relict millipedes in Yugoslavia has been greatly influenced by the process of karstification and paleoclimatic events. These forms are probably the descendants of the ancient epigean hydrophylic and humicolous fauna. With increasing aridity in the past and the formation of different niches underground, these ancient species either evolved as cave inhabitants, or they colonised suitable niches in different epigean shelters.

The origin and development of the rich endemic and residual fauna of both cave and epigean millipedes in Yugoslavia have been affected by the existence of an ancient epigean fauna, by the process of its destruction under unfavourable climatic conditions, and by the subsequent adaptive radiation, enabling the survival of many endangered species. The biogeographical and morphological evidence points to the fact that the Mediterranean area (and the Balkans; including Yugoslavia) represents one of the main refugia of the diplopod fauna.

02-125

TAXONOMIC DIVERSITY OF SPRINGTAILS (COLLEMBOLA, INSECTA) IN YUGOSLAVIA (SERBIA AND MONTENEGRO)

Ćurčić, B. P. M., R. N. Dimitrijević, S. E. Makarov, L. R. Lučić

Institute of Zoology, Faculty of Science (Biology), University of Belgrade, Studentski Trg 16, 11000 Belgrade, Yugoslavia.

The fauna of springtails in Yugoslavia is extremely diverse; out of 240 species, classified into 43 genera and 6 families, only 5 species and 4 subspecies are endemic to Serbia and 4 species to Montenegro; a single species is endemic to both regions, while 4 species occur both in Serbia and/or Montenegro and in adjacent Balkan regions. Seven species occur only in caves and potholes.

The geographic distribution and taxonomic features of endemic and relict springtails point to their different origin and age. The diversification of the rich collembolan fauna in Yugoslavia had been probably due to the continuous development of the ancient Mediterranean stock, its origin to be sought in the Dinaric and Carpatho-Balkan regions. Among the main causes which have affected the evolutionary history of Serbian and Montenegrine springtails, one should emphasise the relative constancy of life conditions in different refugia, as well as the isolation in numerous epigean and underground habitats.

The taxonomic diversity of springtails in Yugoslavia is conditioned by the rich primordial fauna (inhabiting the region in the remote past), by the subsequent survival of different taxa in many habitats, as well as by their adaptation and subsequent differentiation in different niches.

02-127

ZOOLOGICAL DIVERSITY IN THE NETHERLANDS, WITH SPECIAL REFERENCE TO ARTHROPODS

E. J. van Nieukerken, P. Koomen

National Museum of Natural History, Leiden, The Netherlands
An inquiry amongst zoological specialists resulted in a survey of the Dutch multicellular animals. To date 25,200 species are known, of which 24,400 can be regarded as indigenous. When expected but not yet recorded species are included, the total is almost 35,000 species. The arthropods, in particular insects, account for the largest proportion with 71.5% for insects, 7.6% for Arachnida and 5.1% for Crustacea. Compared with most parts of the world the Dutch fauna is poor, with no endemic species at all. Currently the fauna is changing much faster than can be explained by natural causes alone. Already 600 species are known to have disappeared from The Netherlands. The decline is especially severe for aquatic insects (70% of Plecoptera, 40% of Ephemeroptera disappeared), Hymenoptera Apoidea (30% of the species is threatened or extinct), Lepidoptera and Coleoptera.

On the other hand the number of exotic species is increasing, in particular in the larger rivers, the sea and biotopes which are influenced by man (planted forests, towns, gardens, etc.).

Knowledge of the fauna is disproportionate: there are comparatively many more specialists for vertebrates than for the most speciose groups of arthropods. Also nature conservancy and policy focus on vertebrates and a few conspicuous ('nice') invertebrates as butterflies and dragonflies. This disproportionate attention for a minor part of our biodiversity neglects the key-role of invertebrates, particularly arthropods, in the ecosystem.

02-128

MORPHOADAPTATIONS AS A FACTOR OF TAXONOMIC DIVERSITY

V.F.Zaitzev

Zoological Institute, Russian Academy of Sciences,
St. Petersburg, Russia

Biological diversity (BD) is huge manifold problem, from which its concrete aspects can be separated. One of such aspects is taxonomic diversity (TD) reflecting the complicated structure and the hierarchy of the world of living organisms. From the standpoint of a taxonomist studying composition and relationships between groups of animals or plants BD as an objective reality is reflected in TD of these groups and is eventually assessed by the number of species joined in groups of a higher taxonomic rank. Morphoadaptations arising in the evolution and determining biological progress should be regarded among the most important TD factors. Cause and effect relationship between morphoadaptations and TD has been revealed for the Bombyliidae family, one of the largest Diptera taxa. The type of morphofunctional adaptations of adults of bombyliids is to a large extent determined by two processes: transition to obligate nectarophagy and perfection of flight. This is confirmed by a distinct correlation of many morphological structures of adults with length of the proboscis and with character of flight. All representative small genera have mutual correlation of involved morphoadaptations, whereas large genera have a degree of mutual correlation of many functionally important characters. The high level of species diversity therefore is attained in cases where mutual correlation of morphoadaptations provided for biological progress of the groups in the process of its evolution.

02-130

BIODIVERSITY OF AFRICAN TERMITES: AN EVOLUTIONARY PERSPECTIVE

R. Bagine¹, R. Brandl², M. Kaib³

¹ National Museums of Kenya, P.O.Box 40658, Nairobi, Kenya -

² Umweltforschungszentrum Leipzig-Halle, Permoserstr. 15, D-04318 Leipzig, Germany - ³ Lehrstuhl Tierphysiologie, Universität Bayreuth, D-95440 Bayreuth, Germany

In contrast to most other groups of organisms, termites show their highest diversity of genera in Africa, not in the Neotropics. This diversity anomaly is explained by the pronounced environmental changes and fragmentation of biota (especially forests) during the Pleistocene. A further key role to explain the anomaly of biodiversity are the specific biological characteristics of termites to survive in small isolated populations even for long periods of time. Thus the Pleistocene promoted allopatric speciation and evolution of new genera.

Two examples will be presented to illustrate the two factors affecting variation of biodiversity in termites: The lower termite *Schedorhinotermes lamanianus* can survive in small and isolated habitat fragments (lowland forest remnants) over an evolutionary relevant time scale. Such isolated populations show morphometrical and genetical differentiations, which may lead to speciation.

For the genus *Macrotermes* our genetic data provide evidence that the roots of the genus date back to the Miocene, with major diversification within genera in the Pleistocene. During the Miocene the extension of arid savannahs expanded considerably in Africa, facilitating the diversification of fungus growing termites.

02-129

'INSECT HERBIVORY AND BIODIVERSITY IN BELIZEAN FOREST'

Christopher H. C. Lyal

Department of Entomology, The Natural History Museum, Cromwell Road, London SW7 5BD, England.

Evergreen and semi-deciduous forest in the Maya Mountains of Belize is subject to regular hurricanes as well as having timber extracted over the past 400 years. Despite the secondary nature of the forest timber is still being extracted, and the impact of this on insect and plant (seedling) diversity is discussed.

02-131

A FAUNISTIC SURVEY OF TERMITES IN PROVINCE OF KHORASAN

R. Gayourfar

Department of taxonomy research, Plant pest and Disease Research Institute, Tehran, Iran.

Province of Khorasan with about one -fifth of Iran located on northeast, between 31-38 longitudinal. This province has different climate.

During investigation in 1989-1994, 43 sample of different casts has been collected from nest or during nuptial flight. After ecological, ethological, morphological and micrometrical studying, 7 species identified. The confirmation was carried out by Natural Museum of France and UK. The predominant genus is *Anacanthotermes* Jacobson. This genus nearly distributed in all parts of Khorasan, particularly on pasture.

The identification, distribution and ecological aspect are discussed. The identified species are listed as follow:

Family: Hodotermitidae *Anacanthotermes vagans* (Hagen, 1858), *A. turkestanicus* (Jacobson, 1904), *A. ahngerianus* (Jacobson 1904).

Family: Termitidae *Microcerotermes diversus* Silvestri, 1920, *M. turkestanicus* Luppova, 1973, *M. gabrielis* Weidner, 1955, *Amitermes vilis* (Hagen, 1858).

02-132

CORRELATIONS BETWEEN RANGES OF PHYTOPHAGOUS INSECTS AND RANGES OF THEIR HOST-PLANTS

E.P. Nartshuk

Zoological Institute, Russian Academy of Sciences. S.Petersburg, Russia

Ranges of monophagous phytophagous insects occupy usually only a part of ranges of their host-plants. Phytophagous Chloropidae (Diptera) living on grasses and sedges give striking examples of different correlations. Grasses *Phalaroides arundinaceae*, *Dactylis glomerata*, *Deschampsia caespitosa*, *Phragmites australis* have monophagous species of Chloropidae only in the Palaearctic part of their ranges, but not in the Nearctic part. Flies *Chlorops strigulus*, *Dicraeus vagans*, *D. napaeus*, *Calamoncosis glyceriae* are known in the European part of the host-plant ranges, but not in the Caucasian part. Flies *Chlorops gracilis* and *Dicraeus vallis* are known in the European part of the host-plant ranges, but not in the Asian part. Grass *Scolochloa festucaceae* with Holarctic range has monophagous species *Chlorops scolochloae* only in Kazakhstan. Two alternative hypothesis are discussed: migration ability of phytophagous is lower then of host-plants or ecological requirements of monophagous is more narrow then of their host-plants.

02-134

DISTRIBUTION DYNAMICS OF ORTHOPTERA IN THE NETHERLANDS

R. M. J. C. Kleukers, E. J. van Nieuwerkerken

European Invertebrate Survey - The Netherlands, National Museum of Natural History, Leiden, The Netherlands

The recent distribution of Orthoptera in the Netherlands was studied from 1990 to 1994 by more than 100 amateur naturalists. The former distribution was estimated on the basis of detailed study of collections. All data are stored in detail in a database with about 70,000 records. The present-day and former distribution of the 45 species of crickets and grasshoppers is now known in great detail and is presented in an atlas on maps with 5 kilometer squares. The Orthoptera fauna did not remain unaffected by the dramatic changes of the Dutch landscape. Strong decline or local extinction was noticed for species characteristic of heathlands and sand-dunes, such as *Psophus stridulus*, *Gampsocleis glabra*, *Decticus verrucivorus* and *Gryllus campestris*. On the other hand, species associated with unstable habitats such as roadside verges and wasteland are thriving. Several Orthoptera are actually expanding their range, and species as *Conocephalus discolor*, *Meconema meridionale* and *Phaneroptera falcata* entered our country recently. Other species have expanded their range within The Netherlands, probably due to the favourable wheather conditions (i.e. *Chorthippus mollis*, *C. biguttulus*). The accurate data can now also be used for nature conservation purposes and also formed the basis for the Red Data List of Orthoptera in The Netherlands.

02-133

HIGH INSECT DIVERSITY IN A POOR HABITAT (DRY SHEEP-RUNS IN HUNGARY)

L. Papp, L. Ádám

Department of Zoology, Hungarian Natural History Museum, Budapest, Hungary

Pan trapping was performed in two Transdanubian and one Kiskunság NP dry sheep-runs in order to survey aerial plankton as source of the elements of coleopteran and dipteran assemblages (3 hours exposition time at about noon, 30 sample series, 4x4x0.1 m² samples each with nearly 23 000 insects, incl. 18 915 flies). The pan traps seem a proper device to detect insects in the aerial plankton. The number of species is surprisingly high. Altogether ca 500 species of insects were detected (most of the material was identified to species). Among the rare species collected *Homalometopus platycephalus* (Becker) represents a genus new to the Hungarian fauna. Representatives of coprophagous species, autochthonous species of the grassland and also species not developing on pastures were captured: their ratio in Diptera is ca 30 : 20 : 50 %. Although the species in the last group are not members of the pasture assemblages, they must not be neglected: e.g. semi-natural habitats like sheep-runs serve as stepping stones or buffer zones for species developing in natural mosaic habitats.

Only 18 of the 70 coleopteran species, which were collected on sheep droppings were detected in the aerial plankton, while about a half of the 122 dipteran species found on dung were recorded by pan trapping. The seemingly isomorphic habitat proved to be heterogenic for some of the terricolous species, like *Metopina* sp. Some details of the process by which the small coprophagous species colonize the fresh droppings are revealed. This study was supported by the Hungarian Scientific Research Fund (OTKA Nos 3188 and 16892).

02-135

EVOLUTION AND BIOGEOGRAPHY OF HAWAIIAN MIRIDAE (HEMIPTERA)

A. Asquith

U.S. Fish & Wildlife Service, Pacific Islands Ecoregion, HI USA

Four of the eight subfamilies of Miridae have native taxa in Hawaii. The fauna is dominated by the subfamily Orthotylinae with 11 genera, 10 of which are endemic to Hawaii. The other subfamilies have endemic Hawaiian species in nonendemic, widely distributed genera. The diversity of the Orthotylinae fauna is unusually high in Hawaii, representing 73% of the Miridae genera in Hawaii compared to 18% of the world fauna. The geographic origins of most of the Hawaiian taxa have not yet been determined, but at least two taxa have Indo-Pacific affinities and one taxon has its sister-group in North America. In diverse lineages almost all species are single island endemics. Species in smaller radiations tend to be more widely distributed. The single representative of the subfamily Mirinae is the endemic species, *Hyalocephalus pellucidus*, which occurs on all the main islands. The endemic predatory orthotylinae genus, *Kamehameha*, has a species on the remote island of Nihoa, one species on Kauai, and another occurring on Oahu, Maui Nui and Hawaii. In the speciose genera *Sarona*, *Nesiomiris*, and *Pseudoclerada*, there is evidence for sequential colonization and speciation from older to younger islands. In *Sarona*, most speciation events have occurred within an island and are hypothesized to occur by novel host plant colonization. Host plants have also strongly influenced the evolution and speciation of *Nesiomiris*, with most species restricted to single species of Araliaceae, with a single clade switching to Aquifoliaceae. Speciation has also occurred via allopatry within islands and areas of endemism can be identified, including the Makaleha Mountains on Kauai, and the Kaaawa area on Oahu.

02-136

THE FUNGIFAGOUS THIRPS (THYSANOPTERA, PHLAEOTHIRIPIDAE) NOWEL FOR THE TERRITORY OF FORMER YUGOSLAVIA

Ljiljana Andjus¹, Milan Milenković²

The Natural History Museum, Belgrade, Yugoslavia - 1 The Faculty of Forestry, The University of Belgrade

The hypertrophies caused by mistletoes *Viscum album* and *Loranthus europaeus* on various hosts were collected on several sites in Serbia during 1993 and 1994. The collected material contained a large number of insects, including thrips, as was demonstrated by the use of photoelector.

We have identified 4 species of the family Phlaeothripidae. Of these, the following three belonged to the genus *Phlaeothrips*: *P. bispinosus* Priesner, *P. coriaceus* Haliday, and *P. pillichianus* Priesner. The remaining species was *Poecilothrips albopictus* Uzel. All of these species are characteristic inhabitants of the bark and branches of mainly deciduous trees. They even inhabit the holes in the trees made by some Coleoptera and caterpillars. Their nutrition is specific; they feed on the hyphae and spores of mushrooms - they are fungifagous.

The species *Phlaeothrips bispinosus*, *P. pillichianus*, and *Poecilothrips albopictus* have not been found in the countries on the territory of the former Yugoslavia, whereas *Phlaeothrips coriaceus* was previously found in Croatia only.

02-137

INDEX OF THE SAWFLIES (HYMENOPTERA, SYMPHYTA) OF CROATIA

F. Perović, S. Leiner

Croatian Natural History Museum, Department of Zoology
Demetrova 1, 10000 Zagreb
Croatia

Up till now 432 species of Sawflies belonging to the 105 genera and 11 families are noted in Croatian fauna. It is 40% of all known European species, considering the fact that Croatia occupy only 1.2% of European continent.

Within 5 regions in Croatia only 22 species are found in all of them. In East Croatia 255 species (or 59%) are registered, among which 53 are characteristic just for this region. In North Coast region 208 species (48.1%) are registered, with 27 only for this region. The species *Hennedya annulitarsia* which is known only from Gibraltar and Morocco is also found here.

The Highlands and South Coast represented transitional systems from highlands to seashore with equal number of species which is 181 or 182 (or 42%). However, only 25 species are characterized for the Highlands and only 23 for South Coast. Central Croatia is still poorly explored, with 96 species among which 6 are particular for the region.

The peculiarity of species depends on climatic conditions as well as the phytocenosis, characteristic for each of the mentioned regions. (Continental-middleeuropean elements, mountain elements, submediterranean elements and mediterranean elements.)

02-138

POPULATION STRUCTURE, GENETIC VARIATION AND CONSERVATION OF THE CHALK-HILL BLUE BUTTERFLY, *Polyommatus coridon* (Lepidoptera: Lycaenidae), IN SARDINIA

G. Addis¹, R. Crnjar², A. Marchi¹

Dipartimento di Biologia Sperimentale, ¹Sezione di Genetica and ²Sezione di Fisiologia Generale, Università di Cagliari, Cagliari, Italy

The *Polyommatus coridon* species complex is present throughout Europe and is characterized by a patchy distribution in colonies localized in suitable habitats on chalk and limestone. In 1987, its presence was ascertained in the central massif of Gennargentu in Sardinia and it was described as a new subspecies, *P. coridon gennargenti*, based on distinctive wing pattern. We analyzed this taxon by polyacrylamide gel electrophoresis of enzymatic proteins and found it genetically well differentiated and isolated from mainland populations of *P. coridon* and related taxa. Absence of gene flow was indicated by the presence of alternative fixed alleles at the *Aat*, *Gpi*, and *Pgm* loci and significant differences of allele frequencies at other loci. The extremely low level of heterozygosity found in the sample examined and the discovery of other small and isolated subpopulations in the same mountain area, led us to further investigated the genetic structure of this taxon in order to asses the degree of genetic variation within subpopulations, and genetic differentiation and gene flow among them. These data and other biological parameters were evaluated with regard to a possible risk of extinction of the Sardinian taxon following environmental changes.

02-139

ANALYSIS OF LITTER ENTOMOFAUNA IN THREE DISTINCT HABITATS IN TROPICAL REGION IN SERRA NEGRA, SP, BRAZIL.

H. Z. Fischer¹, P. N. Patel¹, S. Greif¹, T. A. Rodrigues¹

Depto. Ciências do Ambiente, CCMB, PUC-SP, SP Brazil..

1-Depto. Zoologia, IB, Universidade Estadual de Campinas, SP Brazil.

Litter entomofauna of forest, *Eucalyptus* reforestation area and abandoned pasture land in the tropical environment were compared. Total twenty samples of soil and litter were collected from each site. Soil humidity, pH, granulation and organic matter contents were analyzed. Litter samples, 0,1m², were collected and examined for the composition of entomofauna. Results were compared through Simpson's and Sorensen's indexes, species constancy and richness.

In species richness forest habitat presented 68.2%, pasture 59.9% and *Eucalyptus* 57.7% of the total estimated species. Maximum species diversity encountered were 98.3% pasture, 95.9% forest and 91.7% in *Eucalyptus*. The most common species in forest were Formicidae (sp3 and sp8), Staphylinidae sp1, Coccidae sp1, Gelastocoridae sp1 and Entombyridae sp2 while in *Eucalyptus* and pasture they were respectively Psychodidae sp1 and Formicidae sp 31. Similarity indexes for the three habitats were 47.2% for pasture/*Eucalyptus*, 45.6% for forest/pasture and 43.3% for forest/*Eucalyptus*. Results indicate that species richness was most in stable environment ("forest") while species diversity was highest in unstable transient environment (pasture habitat).

02-140

RICHNESS AND DIET OF LEPIDOPTERAN FAUNA OF THREE HOST PLANT GENERA IN THE CERRADO OF CENTRAL BRAZIL
I. R. Diniz¹, H. C. Morais²

Instituto de Biologia, Universidade de Brasília, 70910-900, Brasília, DF, Brasil. ¹ Departamento de Zoologia; ² Departamento de Ecologia.
The cerrado is a natural vegetation with variable physiognomies and extreme floristic heterogeneity, covering 22% of the land surface of Brazil. The cerrado has an estimated lepidopteran fauna ranging from 6,000 to 10,000 species. This field study was carried out between 1991 to 1995, in four 1 ha cerrado *sensu stricto* areas near Brasília. Fifteen individuals of each of nine species of host plant were censused every week. The three genera of host plants gleaned for caterpillars were: *Byrsonima* (Malpighiaceae), *Erythroxylum* (Erythroxylaceae) and *Qualea* (Vochysiaceae). Caterpillars were collected and reared to adults using leaves of the species on which they were found as food. More than 16,000 host plants were surveyed and we successfully reared adults of 135 species of Lepidoptera. For each plant genus we found around 55 lepidopteran species, with low faunal similarity among host plant genus. Thirty-six per cent of the identified species were polyphagous. Some were extreme generalists such as *Fregela semiluna* (Arctiidae), *Megalopyge albicollis* (Megalopygidae), *Inga haemataula* (Oecophoridae) and *Hylesia schuessleri* (Saturniidae). The majority of the species had very low frequency, and more data are required to provide adequate information on specialized feeders. However, the results obtained indicated that some species exploit only one host plant genus and showed preference for some species within the genus. This was the case with: *Compsiolechia* sp (Gelechiidae) and *Pococera* sp (Pyralidae) on *Qualea*, *Dichomeris* spp (Gelechiidae) on *Erythroxylum* and, *Chiomara punctum* (Hesperiidae), *Cerconota achatina*, *Gonioterma exquisita*, *G. indecora* (Oecophoridae) on *Byrsonima*. The low proportion of host plants with caterpillars (11%) and the high incidence of rare species appears to be a general pattern for the cerrado. The results lead us to conclude that there is a need for more extensive and independent data sets before generalizations about richness and diet of herbivorous can be made for the cerrado.

02-142

EFFECTS OF DISTURBANCE AND FRAGMENTATION ON THE STRUCTURE, DIVERSITY, AND DYNAMICS OF AMAZONIAN BUTTERFLY COMMUNITIES

Keith S. Brown Jr.¹ and Roger W. Hutchings H.²
¹Depto. de Zoologia, Inst. de Biologia, UNICAMP, Campinas, SP, Brazil and ²Dept. Ecologia, INPA, Manaus, AM, Brazil

The Biological Dynamics of Forest Fragments Project, working in low-productivity upland rainforests 70 km north of Manaus, has given opportunities to follow butterfly communities along the process of disturbance, isolation, and peripheral regrowth of 25 reserves of 1, 10, 100 and 1000 ha. Standardized daily lists (161) of all Papilionoidea observed along transects and at baits were taken between 1980-1995, totalling 35-90 person-hours in each reserve. Of the total 455 species recorded, 88 were seen in only one reserve, while 133 were found in more than half the reserves. During early isolation stages of 12 reserves in 1980-1986, about 32,000 individuals of the common *Solanum*-feeding edge ithomiine (*Hypothyris euclea*) were seen, but it was rare in 1991-1995. The community was dominated by Lycaenidae (255 species) and species of forest understorey sun-flecks (205); 75 species were recorded only on new forest edges. A typical daily list (10 hours) in continuous forest included only 50-70 species; presence of larger clearings or edges increased this by 50-100%. A 10x increase in area of a reserve added only 25% to its total species list, mostly Riodininae; other groups, like larger light-loving species and understorey Satyrinae and Ithomiinae, did not show significant area effects. The turnover (reciprocal of the similarity index) between successive lists in the same reserve averaged 1.63 in 2-4 days, 1.97 after 2-24 months, 2.11 in five years, and 2.40 after change in isolation status, and was larger in continuous forest (2.01) than in isolated reserves (1.76). Most effects on the reserve and daily lists were clearly correlated with disturbance and environmental heterogeneity, rather than size or isolation per se. The general picture of butterflies moving out over the landscape and colonizing any new resources they find, agrees with other diversity studies in richer localities in the SW Amazon. Thus, some butterfly groups can be rapid and sensitive indicators of system disturbance and health. Disturbance-driven fluidity and diversification of butterfly communities in tropical forest has important implications for their monitoring, conservation and management.

02-141

BIOGEOGRAPHICAL PATTERNS OF ALTITUDINAL DISTRIBUTION IN THE SOCIAL WASP FAUNA (VESPIDAE, HYMENOPTERA) OF YUGOSLAVIA

A. Četković, I. Radović
Institute of Zoology, Department of Biology, University of Belgrade, Belgrade, Yugoslavia

The analysis of biogeographical patterns of the social wasp fauna was based on the abundant material from the whole territory of the former Yugoslavia (collected within more than 100 years), and thorough field studies conducted in several characteristic areas. It comprises about 15000 specimens from approximately 350 single or composite localities (covering diverse regions and altitudes), with more than 3100 unit-samples (= unique species/locality/date combinations). The altitudinal distribution spectrum of the component species represents the most notable biogeographical pattern of the regional fauna, as a local reflection of both their different area types and broader ecological (bioclimatic) gradients of the region.
The fauna of Yugoslavia (and Balkan peninsula) consists of 4 genera and 21 species of social wasps (*Vespa* - 2 spp., *Vespula* - 4 spp., *Dolichovespula* - 6 spp. and *Polistes* - 9 spp.), comprising a wide range of faunal elements and zonal types, from Palearctic-subtropical *V. orientalis*, to boreo-montane *Dolichovespula* species. The recorded altitudes ranged from the sea level to about 2300 m, but only few exact records were from the zone above 2100 m. Four major, albeit loosely defined altitudinal zones could be recognized (0 m ⇨ 600 m ⇨ 1100 m ⇨ 1800 m ⇨ above), characterized by different subsets of the recorded species and their relative frequencies. The quantitative analysis of the altitudinal distribution of records within and between the zones, in correlation with the habitat preferences of species, enabled a precise recognition of even subtle ecological and biogeographical differences between species, resulting in a hierarchical classification of local faunal elements.

02-143

BANANA BAIT TRAPPED NYMPHALIDAE (LEPIDOPTERA) AS INDICATORS OF HABITAT QUALITY IN A TROPICAL RAIN FOREST (EASTERN IVORY COAST)

U. Dall'Asta and H. Fermon
Koninklijk Museum voor Midden-Afrika, Entomology Section, B-3080 TERVUREN, Belgium

The "Forêt classée de la Bossematié" (ca. 20 South of Abengourou, Eastern Ivory Coast) is the object of an important project from the GTZ (Gesellschaft für Technische Zusammenarbeit, German ODA). Before the beginning of the project, when the Bossematié forest was not yet protected, logging and poaching were very frequent. The forest became consequently a mosaic of different patches. Some of these are large, others small, some are probably still patches of primary forest, others are so deteriorated that they became overgrown by the bush *Chromolaena odorata*, now a major pest of the forest. A reforestation program is now ongoing in the clearings and the old cocoa plantations. Although the Bossematié forest is in a "bad state", from a certain point of view this state can be considered as an asset for specific research. In this forest, all gradations from nearly primary forest to clearings and plantations are present, and this from small patches to large ones. This became the basis for investigating to which extent large, medium to small patches of the forest can contain a fauna of primary forest. The preliminary study was carried out on butterflies and birds (Waltert, i.l.).
The butterfly data are derived from samples of banana baited traps. Possibly this sampling method needs some standardizing, and it is difficult to comprehend what it can really measure, but it is quite efficient: in the Bossematié forest, in a few weeks, 80 different Nymphalidae species were caught (one of which new to science), most of which can be identified and counted in the field. The fact that this sampling method "attracts" the specimens is one of the elements that forces one to be cautious in drawing conclusions.
Among the first conclusions, which could easily be anticipated, is that the species belonging to the Charaxinae, although typical "canopy species", were found quite commonly in traps placed in degraded habitats. These species are good flyers and if degraded patches are situated near more primary ones, the results can easily be explained. But for some typical forest understorey species belonging to the genera *Euphaedra*, *Bebearia* and *Euriphene*, the results were impressive. These seem not to move at all between the forest patches (were rarely found in traps placed outside the patches), most of the species were indicators of forest patches of "good quality" and a single one could only be found in a patch considered of the "best quality".

02-144

DIVERSITY AND SPECIES ABUNDANCE OF SUBTROPICAL FOREST INSECTS(COLEOPTERA:DIPTERA:HEMIPTERA: HYMENOPTERA:LEPIDOPTERA:ORTHOPTERA) IN MACAU, SOUTH EAST ASIA.

E. Easton, W.W.Pun¹
University of Macau, Macau-1 Departamento de Serviços Agrarios da C.M.I.,Coloane, Macau.

Despite a tiny land acreage comprizing Macau (16.92 sq.Km.),its species diversity is believed to be greater than temperate land areas of comparable size to the north but less than in more tropical areas to the south such as in Malaysia.

A large number of plant species(trees,climbing shrubs,herbs,vines,1296 sp)provide both habitat and a food source for over 145 species of moths and 68 species of butterflies. Rugged hillsides characterize the centers of both islands as well as the Guia hill on the peninsular area connect- ed to China and contain poor soils typicalto that of forested areas in the tropics.

Cerambycid beetle larvae(16sp.)that reside in woody vegetation as well as leaf-feeding adult scarab beetles(10 sp.)are the most abundant among the Coleoptera while the Acridoid grasshoppers (24 sp.) far outnumber species in the family Tettigoniidae(5) or the Gryllidae(7) among the Orthoptera. With the exception of the ants in the order Hymenoptera most of the bees and wasps in the territory are found in the vespoidea(8) and scoliid groups(5) while the pentatomid bugs(16sp) constitute the largest group in the order Hemip- tera. Within the Diptera the mosquitoes(35 sp.) comprize the largest group of fly species due to ample water holding containers. Populations of soil acari and muscoid diptera are limited by the lack of decaying organic matter on the forest floor.

02-146

VARIETY OF THE WING PATTERN IN POPULATIONS OF SOME BLUE BUTTERFLIES (LEPIDOPTERA, LYCAENIDAE) OF THE CRIMEA SOUTHERN SHORE.

Elena A. Artemyeva
Departament of Zoology, Ulyanovsk Pedagogical University, 432700 Ulyanovsk, Russia. Address for correspondence : Prospect Gaja, 55-90, 432035 Ulyanovsk, Russia

Many of blue butterflies have an expressive wing pattern variability on the ventral wing surfaces that has connected with landscape condition. Differences of the wing pattern variety were researched in populations of *Plebejus pylaon* (F.W.), *Glaucopsyche alexis* (Poda), *Cupido osiris* (Meig.), *Pseudophilotes vicrama* (Mr.), *Plebicula thersites* (Cant.) and *Polyommatus icarus* (Rott.) at the Karadag reservation and arounded territories on May-July 1990.

For comparative morphological analysis next wing pattern characters have taken: 1) colour of the hindwing basal portion; 2) colour of the central portion of the borth wings; 3) expression of the submarginal ereescents of the borth wings; 4) expression of the discal spots and external elements; 5) quantity of the marginal spots and its position; 6) quantity of the basal spots and its position; 7) expression of the white dab(s) between the hindwing marginal and external elements.

Results of investigations have cited in Table 1. Enough high thresholds of the wing pattern variety in populations of *G.alexis*, *C.osiris* and *P.icar*us are supported by wealth of inhabitats of Karadag reservation landscapes and great ecological plasticity of these species. *P.py*laon and *P.vic*rama are the most wouDED and its populations endure damage when landscape destructions taken place in territories arounded the Karadag reservation.

Table 1
Thresholds (i) of the wing pattern variety in lycaenid populations of the Crimea Southern Shore.

Species	Karadag reservation	Arounded (unreserved) territories
<i>Plebejus pylaon</i>	0,5	--
<i>Glaucopsyche alexis</i>	0,8	0,2
<i>Cupido osiris</i>	0,9	0,4
<i>Pseudophilotes vicrama</i>	0,4	--
<i>Plebicula thersites</i>	0,6	0,4
<i>Polyommatus icarus</i>	0,8	0,5

Comparison of observed results have suggested that the wing pattern variety is more high in the Karadag reservation than around it { (0,4 ≤ i ≤0,9); n=875; $\chi^2=36,8$; P=0,5}.

Xerophilous tenebrionid beetles (Coleoptera: tenebrionidae) from South-East Transbaicalia

I B Knorr, I I Ljubechanskii, R Ju Dudko
Institute of Animal Systematics and Ecology SD RAS, Novosibirsk, Russia

It is well-known that Siberia is not reach of the Tenebrionidae species Nevertheless, this very peculiar group of Coleoptera attraets attention of the researchers in this region The investigated region is situated close to Mongolia, which have quite an authentic and diverse fauna of the Tenebrionidae We registered 15 species of this family in the South-East Transbaicalia (the zonal steppes of the Onon Dahuria and the Uldzah-Thorei valley near large salt Thorei Lakes) Most of them, as expected, are representatives of the Mongolian fauna This fauna have the north-east border in the studied region The table of species is given below

Tribe	Genus	Species
Tentyrini	Anatolica Eschscholtz, 1831	A undulata (Gebler, 1832)
		A aucta (Faldermann, 1835)
	Seytosoma Reitter, 1895	S pygmaeum (Gebler, 1832)
		M angulosa (Gebler, 1832)
Blaptini	Blaps Fabricius, 1775	B rugosa Gebler, 1825, B miliaria Fischer-Waldheim, 1844, B reflexa Gebler, 1832, B variolosum Faldermann, 1835
Platysechini	Platysechis Latreille, 1818	P brevis Baudi, 1876
Opatrini	Gonocephalum Solier, 1834	G. reticulatum Motschulsky, 1853
	Opatrum Fabricius, 1775	O subaratum Faldermann, 1835
	Melanesthes Dejean, 1834	M faldernanni Mulsant et Rey, 1859
Phalerini	Paranemua Heyden, 1892	P bicolor Reitter, 1895
Cryptini	Crypteus Latreille, 1817	C quisquillus Linnaeus, 1761
		C rufipes Gebler, 1830

HOW DO NERVE CELLS COMPUTE?
DENDRITIC PROCESSING OF MOTION-INFORMATION IN
VISUAL INTERNEURONS OF THE FLY

A.Borst, J.Haag, Friedrich-Miescher-Laboratory of the Max-Planck-Society, Tuebingen, Germany

Dendrites are not just electrically passive structures acting as simple summators of their synaptic input. Instead, dendrites are, quite in general, equipped with a variety of different voltage-gated ion channels. We are interested in the functional consequences of this complex physiology of dendrites for the computational properties of nerve cells. We investigate this problem in the so-called tangential cells of the fly visual system. There exist about 60 of them in each hemisphere of the fly brain each of which can be identified individually. On their large dendrites, they receive input from hundreds of retinotopically organized local motion-sensitive cells. Due to their location right underneath the surface of the brain together with their two-dimensional arborization pattern, these cells are amenable to a variety of electrophysiological and optical recording methods, and, at the same time, allow for a stimulation of their dendrites by the natural synaptic input in vivo. We combine our experiments with computer simulations taking into account the detailed anatomy of the cells as obtained from 3D-reconstruction. Comparing the response properties of different types of tangential cells, only one of which is equipped with a fast sodium inward current in its axon as well as in its dendrite, we found that cells with fast activating sodium currents can respond to temporal changes in their synaptic input signals up to much higher frequencies than those which lack such currents. Thus, fast sodium currents lead to a frequency-dependent amplification of synaptic signals, enhancing cellular responses specifically to transient inputs which otherwise would be attenuated due to the passive properties of the dendritic tree.

03-001

SPATIAL VISION AND EYE DESIGN IN INSECTS

E. J. Warrant
Department of Zoology, University of Lund, Lund, Sweden

Light availability has driven the evolution of the two major compound eye designs found in insects. Superposition eyes, which sacrifice spatial resolution for an improved photon catch, are common in insects active in dim light. Insects active in bright light typically have apposition eyes. These eyes are adapted to provide the maximum resolution possible, often leading to "foveal" eye regions of higher acuity.

Even though superposition eyes are typical for dim-light insects and apposition eyes typical for bright-light insects, there are many fascinating exceptions to this "rule". Many insects have been forced (by competition for example) to occupy niches with light intensities that are not optimal for their eye designs. This has led to surprising optical and neural adaptations which have re-optimised the eye to the new niche. After reviewing the way in which compound eye design affects spatial vision in insects active at different light intensities, I will describe two remarkable eyes which provide exceptions to the "rule": the superposition eye of the fast-flying day-active hawk moth *Macroglossum*, and the open-rhabdom apposition eye of the cave-dwelling beetle *Zophobas*. These two eyes exemplify the ways in which the trade-off between spatial resolution and the sensitivity to light can be radically manipulated during evolution, despite its initial setting by the ancestral eye design.

03-003

THE REGULATION OF DAILY PLASTIC CHANGES OCCURRING
IN CELLS OF THE FLY'S OPTIC LOBE

J.A. Meinertzhagen and ¹E. Pyza
Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada; and ¹Zoological Museum, Institute of Zoology, Jagiellonian University, Kraków, Poland.

The nervous systems of insects exhibit a number of forms of plasticity. Not only are external factors, such as the insect's experience in adult life, important, but intrinsic rhythms also modulate structural and functional properties of the nervous system. In the fly's visual system, for example, two clear cases of structural plasticity have a daily rhythm. In the first optic neuropile, the lamina, of *Musca domestica*, monopolar cells L1 & L2 receive input from photoreceptors R1-R6; L2 in turn feeds back upon R1-R6. The numbers of feedback synapses show cyclical changes. They are more numerous: a) during the night than during the day; and, when the fly is held under constant conditions, b) during the fly's subjective night than during subjective day, thus showing a circadian rhythm. The axons of L1 and, even more, L2 also swell in size during the day, shrinking by night. This second rhythm is apparently controlled by diffuse arborisations from at least two sets of modulatory neurones. One of these, immunoreactive to the peptide PDH, in *Drosophila* also expresses the product of the clock gene *period* (*per*), which is essential for the expression of circadian rhythmicity. The second, LBO5HT, is immunoreactive to 5-HT, which is widely invoked in insect circadian rhythms. Injections of these two putative modulators, or other manipulations of their action or of their cells of origin, are all compatible with a role for both in mediating changes in cell size. They do not distinguish between the actions of the two systems, however, which both increase size in L1 & L2. The LBO5HT and PDH cells both distribute varicose neurites to the lamina, but even though the varicosities are sites of presumed release they apparently lack presynaptic ribbons and direct postsynaptic elements, and thus probably release non-synaptically. Neither the relationship between the size changes in L1 & L2 and synaptic changes in L2, nor the function of either change, is currently clear, nor is the mechanism by which either modulator effects such changes. But the widespread tangential distribution of LBO5HT and PDH neurites throughout the optic neuropiles does suggest that these are merely one of various examples of such plasticity occurring in the optic lobe, that have a recurrent daily basis as consistent as is the coming of each day. Supported by HHMI grant 75195-543701 and MRC grant MT-13242.

03-004

BINOCULAR VISION IN THE PRAYING MANTIS

S. Rosset

Institut für Biologie I
Universität Freiburg, FRG

Visual guidance of prey capture in mantids involves binocular information, but how the brain unifies the inputs from the two eyes is not known. In behavioural experiments, this problem was analysed by presenting the insect with two or more targets simultaneously. From the results it can be concluded that the visual system is able to match pairs of retinal images which correspond to the same object in space. The matching process requires, however, the targets to be separated by at least 20°. If the gap between the targets is smaller, then each eye fuses the retinal images and the binocular interactions are performed as if a single object were present in the field of view. Binocular target separation is therefore based on a very rough angular scale. One implication of this finding is that the ambiguity problem of stereo-matching does not exist in mantids, because potential false matches are associated with disparities which are too large to be detected by the visual system.

03-006

HOW GRASSHOPPERS SEE AND REACT TO MOVEMENTS.

P.J. Simmons and F.C. Rind

Department of Neurobiology, University of Newcastle upon Tyne, UK.

In Acridids, the largest neurons which descend the nerve cord from integrative sensory centres in the brain to motor centres of the thoracic ganglia convey information about visually detected movements. These neurones include a group of three which, by responding to input from the ocelli as well as the compound eyes, monitor shifts in the visual horizon and act to stabilise flight attitude. Another large descending neurone responds to widefield rotational movements of the type which elicit optomotor responses, and the presynaptic neurone to this, in the lobula, has been characterised.

The most intensively studied neuron is the descending contralateral movement detector (DCMD), and this is directionally sensitive to movements in depth, responding with accelerating bursts of spikes to objects approaching the eye. The selectivity of the DCMD for approaching rather than receding objects is achieved monocularly through two different visual cues: an increase in the amount of edge in the image; and an increase in the rate of travel of image edges. Each spike in the DCMD is mediated by a spike in the lobula giant movement detector (LGMD). We have discovered that other large neurons in the lobula also display sensitivity to motion of objects in depth. Modelling studies have demonstrated that this selectivity is probably implemented by a simple network connectivity strategy.

03-005

VISUAL DISTANCE DISCRIMINATION IN INSECTS: AN INDEX OF THE USE OF MOTION PARALLAX

K. Kral

Institut für Zoologie, Karl-Franzens-Universität, Graz, Austria

Experiments have shown clearly that some insects use their own movements in visual measurement of the distance to stationary target objects. In doing so, they take advantage of the fact that nearer objects shift at a greater angle and faster than more distant ones (motion parallax). In addition, in the course of evolution, locusts* and mantids have developed the ability to use side-to-side head movements, or so-called peering movements, to make absolute determination of the jump distance to target objects. Although these two species have very different life styles, as expressed in their different morphology as well as in the optical characteristics of their compound eyes, they use quite similar strategies. Locusts enlarge their peering movements (amplitude and speed) with object distance to an extent that keeps retinal image movement about the same at all distances. Mantids also increase peering amplitude with object distance, but keep the peering speed generally constant, whereby it must be assumed that the peering movement (amplitude) is controlled by the image movement (speed). For both species, peering behaviour suggests that the animal's own active movement is taken into account in distance measurement using motion parallax. It is significant that both species require two completely intact compound eyes for absolute distance measurement. In mantids, the area of higher spatial resolution in the most frontal part of the compound eye, i.e. the fovea, seems to play an important role; this has not been studied in locusts. In this context, it cannot yet be said whether parallax measurement is based on a positional or frequency mechanism. During a peering movement, the image of the object could be registered in different areas of the eye (relationship to fovea), or, however, the information on parallax could be contained in the time that elapses between the activation of the sensory cells of neighboring ommatidia or rows of ommatidia. *Collett, T. S. (1978), *J. exp. Biol.* 76, 237; Sobel, E. C. (1990), *J. Comp. Physiol.* 167, 579. Supported by Grant No. P10861BIO from Austrian Science Foundation

NEURAL MECHANISMS OF POLARIZED SKYLIGHT NAVIGATION IN INSECTS

T. Labhart

Zoologisches Institut der Universität, Zürich, Switzerland

Apart from the sun, the e-vector pattern of polarized skylight offers a reference for visual compass orientation. Many insects are able to exploit this polarization pattern for navigation or course control. Although all microvillar photoreceptors are potentially polarization sensitive, it is just a small group of specialized receptor cells in the dorsal rim area of the compound eye that are dedicated for polarization vision. The microvilli of these receptors are strictly aligned along the rhabdom rendering them strongly polarization sensitive. In the rest of the eye the microvilli are misaligned, which reduces or even abolishes polarization sensitivity. Each dorsal rim ommatidium contains two sets of receptors with their microvilli oriented 90° to each other, i.e. they are tuned to different, orthogonally oriented e-vectors. Polarization vision is monochromatic; it is based on UV-receptors (bees, ants, flies), blue-receptors (locusts, crickets) or green-receptors (cockchafer). In several insects the dorsal rim ommatidia are also optically specialized having strongly extended visual fields.

In the optic lobe of crickets, polarization-sensitive interneurons were found. The spike activity of these neurons is a sinusoidal function of e-vector orientation with an excitatory and an inhibitory part, and with the maxima and minima separated by 90°. Thus, these so-called POL-neurons are polarization-opponent neurons receiving antagonistic input from two analyzer channels with orthogonal tuning orientations. We believe that the two channels are represented by the two sets of receptors with orthogonally arranged microvilli present in each ommatidium. The antagonism makes the polarization signal insensitive to intensity modulations and enhances e-vector contrast. Evidence that this antagonism is a general principle in polarization vision is given by behavioural experiments with bees, and by the conspicuous orthogonal microvillar arrangement in the dorsal rim ommatidia of insects belonging to different orders (Odonata, Orthoptera, Coleoptera, Hymenoptera, Diptera). Another, possibly general mechanism is the integration of e-vector information from a large area of the sky. Field measurements using an opto-electronic model of a POL-neuron indicate that this improves signal quality by evening out disturbances of the polarization pattern by clouds or terrestrial objects.

03-008

CENTRAL MECHANISMS OF FORM PERCEPTION IN INSECTS

D.C. O'Carroll

Department of Zoology, University of Cambridge, Cambridge U.K

The lobula complex of the insect optic lobes has a columnar organisation and layered-terminal structure that is reminiscent of the mammalian visual cortex. Recent recordings from this neuropil described units with 'high-order' properties such as small target selectivity (the 'hypercomplex' property) and orientation selectivity - also reminiscent of cells in the cortex (O'Carroll (1993), Nature 362, 541-543). Given the role of the cortex in processing complex spatial information, it seems likely that these 'cortex-like' pathways are involved in similar tasks. Behavioural analyses provide evidence for relatively sophisticated pattern recognition capabilities in some insects.

I have used intracellular recordings from small and medium-field units in the lobula complex of flies and dragonflies to investigate how the response properties may derive from the anatomical and spatial organisation of the inputs. This reveals a diversity of spatially complex receptive fields. Most cells lack a concentric or circular receptive field organisation and rather have at least two (and in some cases as many as four) spatially distinct sub-regions. These are often elongated and with differing orientation of the long axis. Some sub-regions are inhibitory, while others are excitatory. Dye injections of medium-field units (receptive fields ca. 20° across) reveal an anatomical structure consistent with the spatial properties. In many cases, units have two or more spatially distinct, 'flattened' dendritic regions.

I have yet to encounter units which are exact analogues of specific cell types in the mammalian cortex, but the receptive field organisation of these cells is consistent in many respects with simple 'cortical' models for properties such as orientation selectivity and hypercomplex behaviour. It seems likely that these cells contribute to pathways that provide the basis for tasks such as object and pattern recognition.

03-010

GLIAL JUNCTIONS, DIFFUSION BARRIERS AND ELECTRICAL COMPARTMENTS IN THE INSECT NERVOUS SYSTEM.

S.R. Shaw

Institute for Neuroscience, Department of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada.

Insects possess a potent blood-brain barrier (BBB) that prevents test tracers injected into the haemolymph (dyes, lanthanum, peroxidase) from penetrating into the central nervous system (CNS). In a few of the most ancient insect Orders, dyes can penetrate from the blood into the extracellular space around the photoreceptors, but recent groups have evolved a blood-eye barrier (BEB) proximal to the retina. This seals or slows the diffusional route into and out of the retina. In muscomorph Diptera, the cells at the BEB interface resemble those that form the general BBB, so that the BEB may simply represent an inward ingression and closure of the older BBB, underneath the retina, cutting this off from the rest of the optic lobe of the brain.

The sealing mechanisms responsible for forming these barriers are still unclear, but are probably associated with a sub-type of septate junction on membranes of particular sheath-like glial cells, which result in very large dimensional changes in the extracellular route. No definitive tight junctions have been shown to exist at the site of either the BEB or BBB, although in the eye these are clearly present just below this, in the lamina neuropil. In the lamina, tight junctions are present on different (epithelial) glial cells, and serve to electrically isolate the extracellular compartment of each synaptic complex (optic cartridge) from that of its neighbours, at a location actually inside the BEB.

The blood-brain barrier is believed to retard access to the CNS of diet-related ion changes in the haemolymph, for instance changes in K⁺ concentration, preventing K⁺ from depolarizing neurons and disrupting neural function. It therefore should be characterized by a high electrical resistance, the result of restriction upon the movement of small ions. Paradoxically, an earlier analysis of the transcellular route at the surface of the nerve cord revealed only a moderate extracellular resistance. By contrast, examination of the eye's barrier reveals large variations of measured resistance with depth. The results are consistent with extreme occlusion of the two parallel extracellular routes at the site of the BEB, one between glia, the other between glia and the photoreceptor axons.

VISUALLY-GUIDED NAVIGATION BASED ON OPTIC FLOW IS IMPROVED BY RETINAL SCANNING

F. Mura, N. Franceschini

C.N.R.S./Laboratoire de Neurobiologie, Neurocybernetics study group; 31, Chemin J. Aiguier, 13009, Marseille, France

Some years ago, we drew lessons from insect neuroethology and neurobiology to build a 10 kilogramme visually-guided and autonomous robot equipped with a compound eye, which could move about at a relatively high speed (about 2 body-lengths/second), avoiding obstacles while running towards a target (1,2). Meanwhile, this bionic approach generated a rich feed-back towards biology by pointing to the limitations of the natural system which had constituted the source of our inspiration (the fly). This led us to ask new and relevant biological questions.

Among the physiological spin-off of this robotic approach is the finding that, in spite of their immovable dioptrics, the fly's eyes can in some cases display 'binocular vergence' (3,4). This finding has now led us to examine the possible role of 'retinal scanning' in the context of motion perception.

There are two basic limitations of a compound eye operating on the basis of Local Motion Detectors (LMD's) and driving an agent (animal or robot) in transitory steps of finite length ΔL. These limitations are: (i) the range of vision varies in proportion to the step length (5), (ii) the range of vision becomes dramatically small around the pole of the optic flow field (heading direction). It turns out that retinal scanning can alleviate these two limitations, if the visual axes of the eye are made to rotate smoothly in the anterograde (regressive) sense during every translational step made by the agent. A controlled scanning of this kind considerably enhances the field of vision and detectability of the eye. This novel, biologically inspired principle was first validated via simulation and then implemented onboard a new experimental robot, which was equipped with (i) a single 'vertebrate' camera eye, (ii) an array of 'fly' LMD's, (iii) an electromagnetic scanner

With only 24 pixels, this robot manages to use its vision to navigate safely in an arena without bumping into the contrasted walls.

TIGHT JUNCTIONS IN INSECT TISSUES - AN HISTORICAL OVERVIEW

N.J. Lane, Department of Zoology, University of Cambridge, Downing St., Cambridge, England.

Over the years there has been an ongoing controversy as to whether or not insect tissues possess typical occluding, or 'tight' junctions. It has been clearly demonstrated that these organisms have permeability barriers, in such systems as the brain (central nervous system (CNS)), testis and eye. The precise morphological basis of the blood-brain barrier, and blood-testis barrier, has been hotly contested. Initially it was considered that the septate junctions, junctional structures unique to the invertebrates, were the physiological equivalent to the tight junctions found in vertebrate tissues and established there as the structural basis of barriers. However, unequivocal tight junctions with all the features of the vertebrate intercellular structures, were shown to occur in the modified glial cells, (the equivalent of vertebrate endothelia), surrounding the brains of the arachnids; very similar but simpler structures were observed in insect CNS and testis. In insects, there is a complex spiral arrangement of the outer glial cells of the perineurium, that ensheathes the avascular CNS. These cellular processes overlap extensively and form autocellular junctions which, although relatively infrequent, may be effective in forming a permeability barrier. This has led to speculation that the tight junctions of insects need not be so complicated in organization as those of arachnids and vertebrates. This is reflected in the observed extent and distribution of their component intramembranous fibrils in freeze-fracture replicas. Models can be constructed of their likely structure and possible mode of assembly.

03-012

THE STATUS OF THE SUPERFICIAL CELLULAR COMPONENTS OF THE INSECT NERVOUS SYSTEM.

John S. Edwards,
Department of Zoology, University of Washington
Seattle WA 98195.

This presentation is dedicated to the memory of Dr Berta Scharrer, whose pioneering studies of the insect nervous system addressed a key issue for consideration in this symposium. She made a clear distinction between the connective tissue cell layer that overlies the central nervous system where it secretes the neural lamella, and the outermost investing layer of glial cells.

It is now established from studies with the twist mutant in *Drosophila* that the outermost embryonic glial cell layer can generate a functional ion barrier in the absence of mesodermal cells, and that this layer develops relatively early in embryogenesis. It is recommended that this layer be referred to as the barrier glial layer since the term perineurial glia has been loosely used to include the connective tissue cells together with the outermost glial cells.

While a single cell layer is sufficient to constitute an ion barrier in the embryo, a multilayered barrier in larger insects is not precluded.

The ion barrier is well established in terms of structure and function for the central nervous system, but the status of the barrier on peripheral nerves is in need of further study.

REVIEW ON OVARY DEVELOPMENT AND PHYLOGENY OF INSECTS

J. Büning

Zoological Institute I, University of Erlangen, Erlangen; Germany

Insect ovaries develop from a somatic mesodermal sheath, to which germ cells migrate from the posterior egg pole and settle in regions of the 3rd to the 7th abdominal segment. The somatic sheath bends into a gonadal tube and germ cells will move finally into a ball shaped or elongated ovary anlage. There, apical and basal mesodermal cells undergo further differentiation by which ovarioles will separate; i.e. insect ovarioles do not follow segmental boundaries but are produced by secondary processes inside an existing, sac shaped ovary. Within each ovariole, cluster behaviour of germ cells will raise the different types of insect ovarioles: panoistic, polytrophic meroistic and telotrophic meroistic, while germ cell - somatic cell interactions are necessary during differentiation programs of oocytes, nurse cells and follicular cells.

All insect (Ectognatha) orders have ovarioles or have lost this type secondarily due to parasitic way of life (Strepsiptera). The sister group of true insects are the Endognatha, which have all but one sac shaped ovaries, as do have Chilopoda, Myriapoda and other related groups. The exception among Endognatha are the Japygida which develop ovarioles, nearly identical to ovarioles of true insects. Thus, a revision is made by which Japygida and Insecta (Ectognatha) will form the new taxon "Ovariolata". A second revision is proposed by the raise of the basic type of the polytrophic meroistic ovary: the taxon "Meroista" includes the Dermaptera, the Acercaria and the Holometabola.

DIPTERAN BLOOD-BRAIN BARRIER;
CURRENT FINDINGS, FUTURE PROSPECTS

JUANG, J.-L., S.D. CARLSON¹, S.L. HILGERS¹

Department of Oncology, McArdle Laboratory for
Cancer Research, UW, Madison, 1. Department of
Entomology; Neuroscience Training Program,
University of Wisconsin, Madison, WI, USA.

The blood-brain barrier (BBB) insures brain function in vertebrates and insects by maintaining ionic integrity of the extraneuronal bathing fluid. We have studied this important redoubt in immature dipteran (*Delia*, *Drosophila*) flies. There are key ultrastructural and functional analogs between the BBB of a fly and that of vertebrates. Septate junctions are the invertebrate functional analogs (as a blockade to tracer) to vertebrate tight junctions. Both junctional types also exhibit genetic and molecular kinships, based on the work of others. Anionic domains lining luminal surfaces of vertebrate epithelial cells are similar to a charge-selective stratum we found in the neural lamella of the CNS of the *Drosophila* larva. We find that hyperosmotic and Ca⁺⁺ chelating agents breach the BBB as they do in vertebrates. The barrier in the larva is based on occlusive septate junctions between perineurial cells, while in the embryo the first appearance of the barrier is in recently formed septate junctions between glial cells of nascent chordotonal organs in early neurogenesis. At that time the CNS is unprotected, but by Stage 17 the CNS is fully vested with a BBB. We suggest the BBB initiates in the PNS and probably accompanies PNS axons to the CNS which later gains its own barrier prior to attaining electrophysiological competence. An over-all perspective of the dynamics of the BBB from early neurogenesis to pupal life is presented. Basic studies of fly BBB may have specific import in insect toxicology; *Drosophila* may prove to be a useful animal model for BBB research in general. Supported by NSF (BNS 8908081), State Transitional Fund and Hatch Project 3857.

GERM CELL CLUSTERS AND GERM CELL ACTIVITY IN
NEUROPTERAN OVARIES.

J. Kubrakiewicz

Department of General Zoology, Wrocław University, Poland

Precise analysis of polytrophic ovary structure in Neuroptera revealed the unusual organization of their germ cell clusters. In all species studied so far (representatives of 5 families) cystocytes divisions are asynchronous so the clusters with variable and unfixed number of cystocytes are formed. Moreover, spatial organization of cystocytes connections is not typically branched, but rather linear (only a few branching sites could be observed). The oocyte is located in the central, always linear part of the cluster and therefore is directly connected via intercellular bridges with only two nurse cells.

Linear character of germ cell clusters in Neuroptera is conditioned by asynchrony of cystocytes divisions. Mitotic activity is limited to the terminal parts of the cluster so although the number of cells may grow branching does not appear. Cessation of mitotic activity by some cystocytes enables their earlier differentiation and thus leads to an early diversification of germ cells within the cluster.

03-016

FORMATION AND DIFFERENTIATION OF GERM CELL CLUSTERS IN HYMENOPTERANS

S.M. Biliński, A. Jabłońska

Department of Systematic Zoology, Institute of Zoology, Jagiellonian University, Kraków, Poland

Oogenesis of 5 hymenopteran species (*Cosmoconus meridionalis*, *Chrysis ignita*, *Vespa germanica*, *Mutilla marginata* and *Campanotus* sp) have been analysed. Ovarioles of investigated species as those of other hymenopterans are of the polytrophic-meroistic type. Within ovarioles, terminal filaments, germaria and vitellaria can be distinguished. Germaria of social species (*Vespa germanica* and *Campanotus* sp) are additionally differentiated into 2 well defined regions. In the anterior one mitotic divisions of germ cells take place. Resulting germ cell clusters differentiate into oocytes and nurse cells in the posterior region of the germarium. Vitellaria contain egg chambers in a linear arrangement; each egg chamber is composed of an oocyte and species specific number of nurse cells. In all examined species the contact of the oocyte with accompanying nurse cells is ensured by a cytoplasmic extension of the anterior oocyte pole, termed the nutritive appendix. The apex of the appendix is markedly expanded and bears all intercellular bridges that join the nurse cells with the oocyte. Distribution of microtubules and microfilaments have been studied in oocytes and nurse cells throughout the process of oogenesis. We show that in hymenopterans, as in *Drosophila* cytoskeletal elements play a role in such processes as: differentiation of germ cell clusters, positioning of organelles within ooplasm, transportation of macromolecules from nurse cells to the oocyte. We found however, several important differences between fruit fly and our model system.

03-018

THE ROLE OF TRANSCRIPTION FACTORS IN DORSAL-VENTRAL PATTERNING DURING *DROSOPHILA* OOGENESIS

T. Hsu¹, C. Bagni, J.D. Sutherland, T. Kozlova, and F.C. Kafatos
European Molecular Biology Laboratory, Heidelberg, Germany - 1) Center for Molecular and Structural Biology, Medical University of South Carolina, Charleston, SC USA

Establishment of dorsal-ventral polarity during *Drosophila* oogenesis is initiated by transmission of a "dorsal signal" from the oocyte to the overlying anterior dorsal follicle cells via the EGF receptor pathway. As a result, this population of follicle cells undergoes changes in cell shape, cell migration, and specific gene expression. Ultimately these cells synthesize and secrete chorion proteins and contribute to the formation of specialized chorion structures such as dorsal respiratory appendages, the operculum and the micropyle. In this process, the roles of mRNA localization, ligand-receptor interactions and phosphorylation events have been studied extensively, but the final transcription-factor "targets" of the signaling pathways remain elusive. We demonstrate that CF2, a zinc-finger transcription factor, is a key mediator of these processes. CF2 is absent in the anterior-dorsal follicle cells, but present in the remaining follicle cell nuclei. CF2 expression is ubiquitous in ventralized mutant eggs (e.g. *gurken*) and the patch of CF2 absence expands in dorsalized mutants (e.g. K10). Ectopic expression of CF2 leads to ventralization of the egg, whereas loss of CF2 results in dorsalization. We propose that CF2 is a suppressor of dorsal fate. Notably, loss of CF2 leads to formation of supernumerary dorsal appendages. This suggests that CF2 alone may suppress the entire program of dorsal differentiation, at least in certain populations of follicle cells. A second goal is to understand the role of hormone-signalling during oogenesis by examining expression and action of nuclear hormone receptors. The ultraspiracle (USP) and Ecdysone receptor (EcR) gene products are both found in follicle cell nuclei throughout oogenesis. These proteins dimerize and form the functional receptor for 20-OH ecdysone. We have recently identified a new *Drosophila* hormone receptor, DHR38. This receptor is able to dimerize with USP *in vitro* and in Schneider cells, competing effectively with EcR. DHR38 mRNA is also detected during oogenesis; current work includes examining DHR38 protein expression in developing egg chambers. Interestingly, overexpression of DHR38 results in a gross expansion of dorsal material and shortened dorsal appendages with no apparent effect on ventral follicle cells. This phenotype is partially rescued by simultaneous overexpression of USP, suggesting that a direct interaction between the two proteins can occur in flies. Possible mechanisms leading to this phenotype will be discussed. Loss-of-function DHR38 mutants are currently being isolated and will be examined for egg phenotype.

03-017

THE ROLE OF THE *l(1)3Ae*-GENE PRODUCT IN CELL FATE DECISIONS DURING OOGENESIS OF *DROSOPHILA MELANOGASTER*

U. Schäfer, R. Rübsam¹, E. Simmerl, M. Hollmann, J. Büning¹
Institut für Genetik, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany - 1 Institut für Zoologie I, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

We have isolated a viable allele of the *Drosophila l(1)3Ae* = *l(1)zw4* gene, named *l(1)3Ae^{em}*. The ovarian follicles of mutant females display a variety of abnormalities that affect germ cell number, follicle polarity and oocyte-nurse cell differentiation. All of these phenotypes are considered to be due to disturbed interactions between the germ line and prefollicular cells, pointing to an important role for such interactions in germ cell differentiation. The eggs produced by mutant females are never laid. Those retained eggs often have fused dorsal appendages resembling phenotypes from weak torpedo alleles (*top: Drosophila* EGF receptor homologue = *DER*). Flies mutant for both *l(1)3Ae^{em}* and *top* are extremely rare and have more severe defects in oogenesis indicating that the *l(1)3Ae* and *DER* gene products cooperate in the same pathway during oogenesis. We have generated germ cell clones in heterozygous females by employing the dominant female sterile-FLP recombinase technique (Chou & Perrimon, 1992: Genetics 131, 643). Such females lay eggs that also have ventralized eggshells in many cases; this demonstrates that the inability to lay eggs is due to a somatic defect and that *l(1)3Ae* acts in the germ line, i.e. upstream of the EGF receptor. Progress will also be presented in the molecular characterization of the *l(1)zw4* gene. Supported by DFG grants to J. B. and U. S.

03-019

EVOLUTION OF YOLK PROTEIN GENES AND THE REGULATION OF THEIR EXPRESSION IN DIPTERAN INSECTS

C. Tortiglione, N. White and M. Bownes
Institute of Cell and Molecular Biology, University of Edinburgh, Edinburgh, UK
In *Drosophila*, the three *yolk protein* (*yp*) genes are expressed in adult females in only two tissues: ovarian follicle cells and fat body cells. In addition, *yp* expression is limited to part of the follicle cells life time and to those follicle cells overlying the oocyte. Thus sex, tissue and developmentally-specific expression provides an excellent opportunity to understand how a complex pattern of gene expression can be achieved during development. Furthermore *yps* represent the only example of a direct link between the sex-determination pathway and the downstream sex-differentiation genes. We have used comparative evolutionary studies to elucidate the control signals for sex- and tissue-specific gene expression. We cloned the *yp* genes from *Calliphora erythrocephala* and *Musca domestica* and their analysis at the molecular level showed they are very well conserved when compared to the *Drosophila* proteins, not only in their sequence but also in their expression pattern. In order to identify the trans-acting factors binding to cis-regulatory sequences and to analyse their conservation through evolution, we took 5' flanking regions from one *Calliphora yp* gene and one *Musca yp* gene and used them as enhancers with a *lac-Z* reporter. We showed that two fragments of 823 bp and 900 bp isolated from *Musca* and *Calliphora yp* genes respectively, are able to direct correct reporter gene expression in the ovary of the transformed flies as β -galactosidase assays showed staining in ovarian follicle cells surrounding the oocyte and in the border cells at specific developmental stages. However, these enhancers do not confer sex-specificity of expression in the fat body, as reporter gene expression was found in both sexes of the transformed flies. This means that tissue specific trans-acting factors are conserved between these 3 dipteran species, while trans-acting factors conferring sex-specific *yp* expression, eg doublesex (*DSX*) are either not present or have diverged sufficiently to be non functional between species. The conservation of the ovarian regulatory pathway may enable us to identify the ovarian trans-acting proteins directing follicle cell expression. On the other hand the finding that the sex-specificity of expression is not conferred by these heterologous enhancers provides information about the evolution of sex-determination in the dipteran insects have been established suggesting that sex determination mechanisms are evolving much more rapidly than mechanisms governing tissue specific gene expression in *Musca*, *Calliphora* and *Drosophila*.

03-020

DEVELOPMENTAL CONTROL OF *DROSOPHILA* VITELLINE MEMBRANE PROTEIN GENES EXPRESSION.

V. Cavaliere, S. Spanò, D. Andrenacci, G. Gargiulo
Dipartimento Biologia Evoluzionistica Sperimentale,
Università di Bologna, Bologna, Italy

Early embryonic development depends on complex processes occurring during oogenesis which, in *D. melanogaster*, can be easily approached at the genetic, cellular and molecular levels. During late stages of oogenesis, the follicle cells are engaged in the formation of the eggshell layers: vitelline membrane and chorion. The vitelline membrane is composed of a small number of abundant proteins and several minor constituents. The transcriptional regulation of the vitelline membrane protein genes so far cloned is highly coordinated, and the pattern of gene expression for each member of the gene family has been described. We are interested in the study of vitelline membrane protein gene *VM32E* that shows a peculiar temporal and spatial regulation as compared to the other VM genes. We focused our work on a fine dissection of *VM32E* gene promoter by means of germ line transformation experiments. These analyses allowed us to identify in the region from nt -349 to nt -39 upstream the *VM32E* transcription initiation site specific regulatory elements, driving the developmental expression pattern of the *VM32E* gene in the different follicle cell subpopulations.

Acknowledgments: this work was supported by M.P.I. 40% and by C.N.R.: Progetto finalizzato "Ingegneria Genetica"

03-022

CYTOSKELETON OF FOLLICULAR CELLS, CHORIOGENESIS AND EGG SHELLS OF ANOPLURANS AND MALLOPHAGANS

S.M. Biliński, M. Zawadzka, W. Jankowska

Department of Systematic Zoology, Institute of Zoology,
Jagiellonian University, Kraków, Poland

Egg morphology and process of choriogenesis have been studied in the anopluran, *Haematopinus suis* and 3 mallophagans, *Eomenacanthus stramineus*, *Columbicola columbae* and *Lipeurus maculatus*. In all investigated species egg shells are equipped with anterior operculum and posterior hypople. Anterior half of the egg shell of *Eomenacanthus stramineus* is additionally covered with long, variously shaped bristles. Hypopyles always consist of parallel canals that penetrate the whole thickness of the chorion. The main egg shell of mallophagans is solid and devoid of openings. In contrast, egg shell of *Haematopinus suis* is perforated by numerous narrow canals. Described above regions of the egg shells are deposited by morphologically distinguishable subpopulations of the follicular epithelium. In addition to gross morphology, these subpopulations differ also in the distribution of cytoskeletal elements. Two chorionic structures, hypopyles and canals perforating the egg shell of *Haematopinus suis* are formed around processes of the follicular cells. These specialized structures contain numerous microfilaments. During choriogenesis of *Eomenacanthus stramineus* intercellular spaces between anterior follicular cells gradually widen. In these "empty" spaces bristles covering the anterior half of the egg shell are formed. Prior to ovulation, thick bundles of microfilaments arise in the basal cytoplasm of follicular cells. These bundles show muscle-like cross-striations and are apparently involved in the passage of the developed oocyte from the ovariole to the lateral oviduct.

03-021

TERMINAL DIFFERENTIATION OF OVARIAN FOLLICULAR CELLS IN THE SILKMOTH *BOMBYX MORI*: MOLECULAR SWITCHES CONTROLLING A COMPLEX REGULATORY PATHWAY

L. Swevers, H. Qian, F. Kendirgi, T. Eystathiou, I. Lindström-Dinnéztz and K. Jatrou
Department of Medical Biochemistry, The University of Calgary, Calgary, AB T2N 4N1, Canada

Studies in our laboratory are focused on the mechanisms that control the terminal differentiation of ovarian follicular cells in the domesticated silkmoth, *Bombyx mori*. The terminally differentiated state of follicular cells is manifested by the synthesis and secretion of the chorion polypeptides that form the eggshell or chorion whose function is to allow fertilization and protect the developing embryo.

The initiation of oogenesis in silkmoths is controlled by the steroid hormone 20-hydroxy-ecdysone (20E). However, the identity of the components that constitute the regulatory cascade controlled by 20E remains largely unknown. On the other hand, the commitment of follicular cells to their terminal differentiation path occurs during mid-vitellogenesis, 1.5 days prior to the onset of choriogenesis. Commitment involves a secondary regulatory cascade that controls the synthesis of transcription factors required for activation of chorion genes. Our hypothesis is that the primary regulatory cascade that is controlled by 20E culminates in the appearance of a receptor for a circulating ligand in follicular cells. The ligand for this receptor may be a member of the bombyxin family of insulin-like peptide hormones, that are present in the circulation of female (and male) pupae at a time coinciding with the time of commitment of follicular cells to terminal differentiation.

To deduce the validity of our model, we have cloned an isoform of the receptor for 20E (BmEcR), that is expressed in follicular cells, confirmed its identity by a number of functional assays, and analyzed its distribution in follicular cells during oogenesis. Furthermore, work is in progress to achieve three additional objectives: (1) the isolation of cDNA sequences expressed during the earliest stages of oogenesis (the phase preceding the commitment stage) and analysis of their genes to deduce whether the latter are regulated directly by the 20E/BmEcR complex; (2) the cloning of sequences expressed in follicular cells after the establishment of the choriogenic potential (*i.e.*, after commitment has occurred) but prior to its implementation (choriogenesis); and (3) the cloning of the bombyxin receptor(s) that may act in follicular cells as the switch for the second regulatory cascade.

03-023

THE MORPHOGENESIS OF THE EGG CHORION IN *DROSOPHILIDAE* (DIPTERA). A MODEL FOR THE ORGANIZATION OF COMPLEX SUPRAMOLECULAR STRUCTURES IN EUKARYOTES.

Margaritis L.H. & Trougakos LP.

Department of Biology, Division of Biochemistry, Cellular-Molecular Biology & Genetics, Athens University, Athens, Greece.

Chorion in *Diptera* is a complex proteinaceous extracellular structure exhibiting regional and radial complexity that finally assembles in a functional supramolecular structure. This includes, a crystalline innermost chorionic layer (ICL), an endochorion with inner part (floor), pillars and outer part (roof) and an exochorion. The chorion proteins are crosslinked in vivo via the action of a chorionic peroxidase (CP) upon activation by endogenous hydrogen peroxide. Besides its use as a model system in developmental biology, the insect chorion is of great importance to answer questions of evolutionary biology, molecular genetics, supramolecular architecture and physiology.

We have recently focused our research on chorion morphogenesis in *Drosophila virilis* for which there is an increasing accumulation of genetic information. Its chorion is comprised of six major proteins that exhibit a distinct temporal synthetic profile and have been characterised as early (Dvs38, Dvs36), middle (Dvs19, Dvs16) and late (Dvs18, Dvs15) according to the choriogenic stage they are produced. In order to explore the way that the chorion is assembled, specific antibodies have been raised, against the two early, one middle and one late chorion proteins. These antibodies have been used for immunobiochemical and immunocytochemical studies and have revealed that:

a) the chorion proteins are randomly distributed within the endochorion, but they are absent from the ICL. b) all specialised regions (appendages, operculum, micropyle, collar, posterior pole) have been shown to contain all proteins. c) the early proteins alone are organising a structurally complete endochorion. The subsequently secreted middle and late proteins are intercalating amongst the early protein molecules. e) double immunolocalization has shown that the chorion proteins do not coexist in every secretory vesicle, suggesting that the final rearrangement of the protein molecules probably occurs extracellularly.

These results allow us to conclude that during chorion formation a scaffold is first formed consisting mainly of the two early chorion proteins, which is subsequently filled by the middle and the late chorionic proteins. Therefore the system exists in a dynamic equilibrium until the moment that an unknown agent (probably hydrogen peroxide which acts as an activator of the peroxidase) causes the final rearrangement of the components resulting in the hardening of the structure. Furthermore, the fact that these major proteins appear to participate in all the specialised regions, suggests that the structural variability of these regions is most probably due to differential secretory pattern by the corresponding follicle cell subpopulations.

03-024

OOTAXONOMY IN PHLEBOTOMINE SANDFLY (DIPTERA, PSYCHODIDAE).

A.M. Fausto*, M. Maroli** and M. Mazzini*

* Department of Environmental Sciences, University of Tuscia, Viterbo, Italy. **Department of Parasitology, Istituto Superiore di Sanità, 00161 Rome, Italy.

Insect ootaxonomy, based on egg chorionic sculpturing observed by scanning electron microscopy, is well advances for various families of the dipteran order. Among phlebotomine sandflies, many of which are medically important vectors of leishmaniasis and Phleboviruses, the eggs of several species belonging to the Neotropical genera *Lutzomyia* and *Psychodopygus* have been previously examined by SEM.

Recently, we have investigated, by means of scanning (SEM) and transmission (TEM) electron microscopy, the eggshell fine structure of species belonging to the Palearctic genera *Phlebotomus* and *Sergentomyia*. At TEM level, the eggshell appears to have a homogeneous vitelline envelope and a thick chorion. The latter is formed by distinct inner, intermediate and outer layers. At SEM level, the outer chorionic layer shows a characteristic pattern, consisting of small columns arranged in palisade to form sinuous ridges.

On the basis of the chorionic sculpturing, the eggs of the sandfly species were grouped into different morphological categories.

SEM/TEM investigations of the sandfly eggshell show species-specific characters useful for their specific identification. The chorionic features of different species are compared with those of other Diptera and their phylogenetic value is discussed.

03-026

COMPARATIVE MORPHOLOGY OF SENSILLUM DEVELOPMENT

Thomas A. Keil

Max-Planck-Institut, D-82319 Seewiesen

Each insect sensillum is formed by a fixed number of cells which arise via differential mitoses from an epidermal mother cell. One or several bipolar sensory neurons are enveloped by the glia-like thecogen cell, the trichogen, and the tormogen cell. Morphogenesis begins with formation of an apical ciliary (9x2+0) process by the neuron which grows above the epidermal surface. This is followed by the outgrowth of an apical sprout, backed by a microtubular cytoskeleton, from the trichogen cell, which will secrete the cuticle of the sensory hair. The tormogen cell forms the hair socket. After cuticle deposition, the trichogen cell retracts from the hair shaft and, together with the tormogen cell, forms the subcuticular sensillum lymph space.

In hemimetabolous insects in preparation for molting, the dendrite leaves the newly developing sensillum through a lateral or apical pore, remaining connected with the old sensillum. This feature is conserved in holometabolous insects, where during adult development the dendrites also project from the newly forming sensilla although the pupa does not have sensilla to which the dendrites could be connected. When cuticle secretion begins, these dendritic processes are lost. The definite sensory dendrites grow into the hair shaft while the trichogen cell retracts from the latter in most sensilla investigated so far. In many olfactory sensilla, the tormogen cell degenerates at the same time and is replaced by an additional fourth enveloping cell.

DOES CHORIONIC STRUCTURE PLAY A ROLE IN THE ADAPTIVE RADIATION OF THE HAWAIIAN *DROSOPHILA*?

M.P. Kambyseilis, F. Piano, E.M. Craddock¹

Department of Biology, New York University, New York, NY USA - ¹ Division of Natural Sciences, State University of New York, Purchase, NY USA

The endemic Hawaiian *Drosophila* have long been recognized for their extraordinary divergence in external adult morphology, but even more diversity is found in egg size and ultrastructure of the chorion. Among about 100 Hawaiian species analyzed thus far, no two species share identical chorion morphology. Nonetheless, chorion structures in taxonomically related species are more similar than those of different species groups or subgroups, suggesting a genetic basis for the morphological differences and the possibility of tracing phylogenetic trends in chorion morphology. It is hypothesized that much of the divergence in chorion morphology has evolved in response to varied selection pressures in the ecologically diverse breeding substrates used by Hawaiian drosophilids. This fauna has radiated to oviposit in fungi, decaying flowers, fruits, leaves, stems, bark or tree fluxes, these diverse substrates imposing varied demands on the oviposition process and survival of the embryo. To investigate correlations between aspects of chorion morphology and the oviposition substrate we have taken a phylogenetic approach, using an independently derived molecular phylogeny of the Hawaiian species to conduct analyses of chorion characters such as the length of the respiratory filaments, thickness of the outer endochorion, and features of the follicle imprint borders, dorsal ridge, operculum, micropyle, etc. These data allow us to examine whether the evolutionary divergence in chorionic characters has an adaptive basis.

03-027

Genes involved in the development of sensory organ precursors in Drosophila.

Pascal Heitzler, Mare Bourouis, Mare Haenlin, Philippe Romain, Laurent Seugnet and Pat Simpson.

IGBMC, CNRS - INSERM - Université Louis Pasteur, Strasbourg, France.

The genetic control of sensory organ development is being unravelled in *Drosophila*. During development of the peripheral nervous system, the potential to become nerve cells is provided by the genes *achaete* (*ac*) and *scute* (*sc*). They encode bHLH transcription factors. The pattern of bristles on the thorax results from a complex and dynamic expression of *ac* and *sc* at the sites of each future sensory organ. Control of the spatial expression is not understood but several upstream regulatory genes transcription factors are known. These are expressed over part of the thoracic epithelium and have been shown to regulate expression of *achaete-scute* within their domains of expression. *achaete* and *sc* are expressed initially in clusters of cells from which one cell is singled out to be a neural precursor. This cell then prevents the other cells of the cluster from becoming neural by means of an inhibitory signal that results in the cessation of *ac-sc* expression. This is known as lateral inhibition. The signal is mediated by *Delta* that acts as a ligand for the *Notch* receptor. A loss of any one of the components of this signalling cascade results in neural hyperplasia: all of the *ac-sc* expressing cells, instead of just one, follow the neural pathway. A number of genes are also known that act after *ac* and *sc* and play a role in the determination of sensory organ type. Finally the genetic control of the assignment of cell type among the four cells composing the bristle organ has also been partly described.

03-028

COMPARISON OF INSECTS AND CRUSTACEANS
MECHANORECEPTORS
Y. Crouau

Laboratoire d'Ecologie Terrestre, Université Paul Sabatier, Toulouse, France.

Mechanosensitive cells of crustacean setae show important cytological differences compared with those of insects; the mechanosensitive cells of arthropods setae are classified in two groups which are structurally and functionally different; the typical cells of insects setae show a tubular body at the tip of their dendrites (tubular body cell: **tbc**); mechanosensitive cells of aquatic crustaceans never show such a structure and are characterized by a 9+0 cilium and a large ciliary root (chordotonal type cell: **ctc**); among crustaceans, **tbc** are only observed in terrestrial isopods. Therefore, it seems that the type of mechanosensitive cell associated with an arthropod seta is more linked to the physical environment than to the arthropod class. It is also linked to differences in the kind of mechanosensitivity of the two types of cells: **tbc** dendrites would be compression sensitive whereas **ctc** dendrites would be stretch sensitive. The presence of **tbc** in the aerial medium and of **ctc** in the aquatic medium could be explained by the physical characteristics of these two media.

03-030

FUNCTIONAL ANATOMY OF ANTENNAL MULTIPOROUS
GUSTATORY SENSILLA IN SOME PARASITOID
HYMENOPTERA

N. Isidoro, F. Bin

Institute of Agricultural Entomology, University of Perugia, Perugia, Italy

Multiporous gustatory sensilla (MGS) present on females antennae of parasitoid Hymenoptera have been investigated and compared in some species belonging to Scelionidae (*Mantibaria anomala* Kirby, *Telenomus busseolae* Gahan, *Trissolcus basalis* Woll.), Platygastridae (*Amitus spiniferus* Brethes), Trichogrammatidae (*Trichogramma brassicae* Bezdenko) and Diapriidae (*Coptera occidentalis* Mues., *Trichopria* sp.). They are located ventrally with number and pattern remarkably variable in different taxa. In Scelionidae and Platygastridae the MGS are located in median longitudinal row, in small number (3-9/antenna), and innervated by very numerous sensory neurons (120-400/sensillum). Instead in Trichogrammatidae and Diapriidae the MGS are scattered in relatively high number (20-240/antenna) and innervated by few sensory neurons (5-10/sensillum). Outer dendritic segments, usually unbranched or branched in one case, reach the multiporous area which presents peculiar features in different taxa. Accessory glands are in some cases associated with MGS. Their possible role in host recognition is discussed.

03-029

STRUCTURAL AND TOPOCHEMICAL ANALYSIS
OF OLFACTORY SENSILLA IN MOTHS

M. Laue and R.A. Steinbrecht

Max-Planck-Institut für Verhaltensphysiologie, Seewiesen, Germany

The pheromone detection system of male moths was used for a long time as a model in insect olfaction. Milestones were the discovery of elementary receptor potentials, second messenger cascades, and odorant-binding proteins. Topochemistry, in particular immunocytochemistry, has become a link to combine biochemical data, usually obtained from homogenized antennae, with the complex and diverse ultrastructure of antennal sensory organs.

Specific antibodies against odorant-binding proteins (OBPs) and putative key proteins in the transduction machinery now allow for a localization of these proteins on the ultrastructural level. Immunolocalization of pheromone-binding protein (PBP) and general-odorant binding protein (GOBP) in *Antheraea polyphemus*, *Bombyx mori* and other moth species revealed that these proteins are highly concentrated in the aqueous sensillum lymph, which surrounds the dendritic portions of the receptor cells. PBP is predominantly expressed in pheromone-sensitive sensilla trichodea of male moths, whereas GOBP could be detected in sensilla of both sexes, which are sensitive for plant odours and other 'general odours'. Odorant-binding proteins of different classes (PBP and GOBP) are not co-expressed within a given sensillum. The expression of a certain OBP is not correlated with a certain morphological sensillum type but rather with the specificity of the olfactory receptor cells contained. These results favour the hypothesis that OBPs might play a role in stimulus recognition in addition to their transporter and deactivator function.

We also succeeded in the localization of several proteins of suggested significance in the second messenger chain. A G-protein of the Gq-family could be localized in the receptive dendrite of the receptor cells as well as an IP₃ receptor. In addition, Calmodulin and Calcineurin were detected in the olfactory receptor cells. Nitric oxide synthase was found to be highly concentrated in the antennal haemolymph. This enzyme produces the messenger NO which is possibly involved in receptor adaptation via guanylate cyclase. Comparison of the stimulated versus unstimulated state of olfactory sensilla may add further insight in the functional significance of these proteins.

03-031

PERCEPTION OF INFRARED RADIATION BY SPECIALIZED
THERMORECEPTORS IN BUPRESTID BEETLES

H. Schmitz

Zoologisches Institut der Universität Erlangen-Nürnberg, Germany

Larval development of buprestid beetles of the genus *Melanophila* can take place only in trees recently killed by a fire. For the localization of forest fires the adult beetles have metathoracic infrared pit organs next to the coxae of the mesothoracic legs enabling both sexes to detect infrared radiation at long range. Dependent on the size of the beetle, at the unsclerotized bottom of each pit 50 - 100 sensilla can be found. The cuticular apparatus of a single sensillum consists mainly of a massive endocuticular spherule of 12 - 15 µm in diameter. The upper hemisphere of the spherule bulges out and is covered only by a thin mesocuticle of about 1 µm. Except for a small cuticular stalk (diameter 2 µm) connecting the spherule to this outer cuticle, the entire spherule is surrounded by distal processes of two enveloping cells (probably the tricho- and the tormogen cell) forming a flat protoplasmatic double layer of about 300 nm thickness. Therefore the upper region of the outer receptor lymph cavity remains comparatively small. From below the spherule is innervated eccentrically by the distal tip of the dendritic outer segment (DOS) of a single ciliary receptor cell. In the outermost tip of the unbranched DOS, tightly squeezed in the spherule, a well developed tubular body can be found. Apart from the peculiarities of the cuticular apparatus the remaining ultrastructure of the sensillum is highly reminiscent to that one of a cuticular hair mechanoreceptor (sensillum trichodeum). Because transitional stages between infrared receptors and sensilla trichodea can be found and in the posterior slope of the pit so called suppressed infrared sensilla are situated which remain completely below the cuticle and display spherules which are basally flattened and longitudinally stretched, it is postulated that the infrared receptors must have evolved from cuticular mechanoreceptors.

03-032

FUNCTIONAL ROLE OF CYTOSKELETAL ELEMENTS IN INSECT SENSILLA

U. Wolfrum
Zoologisches Institut I, Universität Karlsruhe (T.H.), Kornblumenstr. 13, D-76128 Karlsruhe, Germany

Insects gather information about environmental conditions using special sensory organs, the sensilla. As has been demonstrated in mechanosensitive structures of other organisms, mechanosensitive sensilla of insects possess prominent cytoskeletal elements with characteristic micro-mechanical properties. These properties may play important roles in sensilla function. To get more insights into the micro-mechanics of sensilla, the molecular composition of the cytoskeletal elements in the sensory cells, as well as the auxiliary cells, has been analyzed.

1. The scolopale in the innermost auxiliary cells of the mechanosensitive scolopidia and thermo-hygroresponsive no-pore sensilla are comprised mainly of actin filament bundles. Their filament orientation and the presence of actin-associated proteins (e.g. tropomyosin) indicate that these actin bundles stabilize the scolopale, and their characteristic elasticity is probably involved in stimulus transformation in scolopidia.
2. An additional cytoskeletal component of scolopidia is the prominent ciliary rootlet of the sensory cell. Immunocytochemistry shows that these rootlets are composed of centrin, a small Ca^{2+} -binding protein which forms contractile filaments in green algae. Rootlet contraction in scolopidia may serve in sensory adaptation.
3. In mechanosensitive cuticular sensilla, a prominent cytoskeletal structure - the tubular body - is localized at the tip of the dendritic outer segment of the sensory cells. Present results reveal that the microtubules composing the tubular body are linked to each other by microtubule-associated proteins. This stabilization confirms the hypotheses that the tubular body is forming a rigid core underlying the mechanosensitive membrane of the tip of the sensory dendrite.

SPERM AND EGG SURFACE COMPONENTS POTENTIALLY INVOLVED IN GAMETE INTERACTIONS IN *Drosophila melanogaster*.

M.-E. Perotti¹, F. Cattaneo¹, M. Pasini¹ and J.H.P. Hackstein²
¹ Dept. General Physiology & Biochemistry, University of Milano, Italy; ² Dept. Microbiology & Evolutionary Biology, Catholic University of Nijmegen, Nijmegen, The Netherlands.

In a variety of species sperm-egg recognition involves interactions between glycoconjugates and complementary molecules present on the gamete surfaces. Using cytochemical approaches and biochemical assays, we studied the presence of carbohydrate residues and complementary molecules on the surface of the gametes of *Drosophila melanogaster*.

In the chorion, residues of αMan , αGalNAc and βGal are present on the whole surface of mature ovarian eggs, whereas βGlcNAc , αGal , $\alpha\text{L-Fuc}$ and Neu5Ac residues are restricted to the micropyle. The vitelline envelope (VE) shows a high density of αMan and βGlcNAc moieties in its micropylar portion, over the site of sperm entry. Upon fertilization, no modification in the distribution of the surface sugars occurs in the chorion, whereas αMan and βGlcNAc are no longer detectable on VE.

In sperm of fertile males, binding sites for αMan and βGlcNAc are present on specific domains of the plasma membrane overlying the middle portion of the acrosome and the axoneme terminal tract. Fluorimetric assays indicated the presence on the sperm surface of $\beta\text{-N-Acetylglucosaminidase}$ ($\beta\text{GlcNAc-ase}$) and of $\alpha\text{-mannosidase}$ activities with a pH optimum of 3.9.

In sperm of the male autosomal sterile mutant *ms(3) HB156* that are motile and are transferred to the female but that do not enter the egg, binding sites for βGlcNAc are absent from the acrosomal tract of the plasma membrane and surface $\beta\text{GlcNAc-ase}$ activity is 50% of that present on sperm of fertile males. Binding sites for αMan and $\alpha\text{-Mannosidase}$ activity were as in spermatozoa of fertile males.

The results suggest that $\beta\text{-N-Acetylglucosaminidase}$ on the sperm plasma membrane and βGlcNAc residues on the vitelline membrane play a crucial role in sperm-egg interactions.

03-033

Transcriptional and translational control of gene expression during *D. melanogaster* spermatogenesis: the *Mst23Ea* gene expression as a model.

Giordano E., Di Paola F., Crispi S., Pannuti A. and L.C. Polito.

Dipartimento di Genetica, Biologia Generale e Molecolare dell'Università di Napoli Federico II. Via Mezzocannone 8, 80134, Napoli Italy.

The genetic program leading to the sequential transformation of cellular components during *Drosophila melanogaster* spermiogenesis is achieved at least by two temporally distinct levels of gene expression. Most of the genes required for spermiogenesis are transcribed in the growing phase of the premeiotic spermatocytes several days before their protein products are necessary. Transcription ceases just before meiosis and the successive differentiation program, stored in pretranscribed mRNA molecules, is then controlled at translational level in absence of transcription. In order to gain further insights into the molecular mechanisms regulating this peculiar gene expression of the *D. melanogaster* spermatogenesis we undertook the study of a newly identified *Mst23Ea* gene which is exclusively transcribed in the male germline. Here we report the identification and the study of the cis-regulatory sequences directing the spermatocyte specific transcription of the gene and the postmeiotic spermatid translation of its transcripts. We show that a region from -254 to +27 bp, sufficient for a high level of proper transcription in the male germ line, can be split into two regulatory elements. A first element encompassing the transcriptional start site from -33 to +33 bp is sufficient to guarantee stage and tissue specific transcription of the gene although at a low level. A second element located from -198 to -34 has a quantitative effect on the testis specific expression. The *Mst23Ea* transcript, first synthesized in primary spermatocytes, is translated only in the postmeiotic stages. Sequences localized in the 5' untranslated leader are sufficient to repress translation of the *Mst23Ea* transcripts in the spermatocytes and early spermatids during sperm differentiation. Band shift experiments show that all the *Mst23Ea* regulatory elements bind specifically to protein factors extracted from adult testis.

We are currently investigating the functional role of the *Mst23Ea* gene product using a transgene encoding *Mst23Ea* antisense RNA, *in situ* antibody staining of the endogenous *MST23Ea* protein and *in vivo* localization of a *MST23Ea*- β -galactosidase fusion protein.

AXONEMAL DIVERSITY IN INSECT SPERMATOOZOA

B. A. Afzelius¹ and R. Dallai²

¹Department of Ultrastructure Research, University of Stockholm, Stockholm, Sweden - ²Dipartimento di Biologia Evolutiva, Università di Siena, Siena, Italy

Most animal spermatozoa have a flagellum with a 9+2 pattern (i.e. 9 microtubular doublets around 2 central singlets) or a 9+9+2 one (accessory tubules flank the doublets). The A-tubule of the doublet usually has outer and inner dynein arms. However, outer arms are missing in Ephemeroptera and Trichoptera. Inner arms are missing in spermatozoa of several cecidomyiid Diptera, which nevertheless are motile. When both sets of dynein arms are missing the sperm tail is immotile. Accessory tubules presumably have a supporting role only; their cross-sectional appearance usually is circular, although in Psocoptera+Mallophaga+Anoplura it is elliptic. An intertubular material fills much of the spaces between the accessory tubules (except in Ephemeroptera). In most species the accessory tubules have a wall with 16 protofilaments but in Diplura, Ephemeroptera and Psocodea there are 13, in Phasmida 17, in Trichoptera 16-20, and in Diptera 13, 14, 15 or 16 ones (Dallai & Afzelius, 1990, 1994). The number of doublets may also vary: some species of Cecidomyiidae thus have 10 and 20 doublets in a ring and in Sciaridae and some Cecidomyiidae the number may be even higher. The bizarre sperm flagellum of Thysanoptera is derived from three 9+0 axonemes (Bode, 1983), which merge to form an asymmetric structure consisting of 9 doublets without dynein arms, 9 doublets with dynein arms, and 9 singlet microtubules also with dynein arms. (Dallai & Afzelius, 1991).

03-036

THE ULTRASTRUCTURE AND BIOCHEMICAL CHARACTERIZATION OF AXONEMAL DYNEIN FROM *ASPHONDYLIA RUEBSAAMENI* KERTESZ (DIPTERA: CECIDOMYIIDAE).

P. Lupetti, C. Mencarelli, R. Dallai

Dipartimento di Biologia Evolutiva, Università di Siena, Siena, Italia.

The aberrant structure of *Asphondylia ruebsameeni* Kertész sperm axonemes has been studied by both conventional electron microscopy and quick-freeze, deep-etching techniques. In this species more than 2500 microtubular doublets are disposed in double parallel spirals coiled around an axial core of mitochondria; each doublet is provided with outer arms only. Such a peculiar axoneme shows a bizarre pattern of movement when observed within the deferent duct of adult males. The three-dimensional structure of the dynein arms has been elucidated by quick-freeze, deep-etching preparations of demembranated unfixed sperm-cells. At first glance, the dynein arm shows a domain organization similar to that previously observed in other species of both invertebrates and vertebrates, consisting of a head region formed by two globular domains in close vicinity of the A subtubule and a thin stalk contacting the B subtubule of the adjacent doublet. However, a more accurate analysis of micrographs revealed the presence of a globular extra-component regularly intercalated between the arms.

Outer arms could not be extracted by the high salt treatment usually efficient in the axonemes of other species, and could be removed only by dialysis against a low ionic strength buffer. The high molecular weight polypeptide complement of the solubilized dynein was shown by SDS-page to consist of only one band at ca.300kDa. A polyclonal antibody specific for a synthetic peptide which corresponds to the consensus sequence of the P-loop of both axonemal and cytoplasmic dyneins strongly reacted with this polypeptide. Solubilized dynein exhibited a sedimentation coefficient of about 12S and a Mg²⁺-dependent ATPase activity which was inhibited by vanadate.

Our preliminary data suggest that *Asphondylia* sperm dynein could be the first model of a two-headed axonemal dynein in which the two heads are formed by the same polypeptide, a feature commonly found in cytoplasmic dyneins.

03-038

MORPHOLOGICAL CHANGES OF EUPYRENE AND APYRENE SPERM WITH TIME AFTER MATING IN THE FEMALE REPRODUCTIVE ORGANS OF THE BUTTERFLY *ATROPHANEURA ALCINUS* KLUG (LEPIDOPTERA: PAPILIONIDAE)

M.Kubo-Irie, T.Shinkawa, T.Mohri, T.Nakazawa and H.Mohri¹.

Biological Laboratory, University of the Air, Mihama-ku, Chiba, Japan
-1 National Institute for Basic Biology, Myodaiji, Okazaki, Japan.

The male and female butterflies, *Atrophaneura alcinous*, were mated by the hand-pairing method. To examine the sequence of sperm passage, samples were dissected out from male and female reproductive organs with time from the onset of mating. They were observed under a microscope after vital staining with fluorescent dye and under an electron microscope after ultrathinsectioning.

Spermiogenesis occurred simultaneously within a cyst in the testis. Eupyrene sperm bundles migrated into the vas deference, whereas apyrene sperm were not in a bundle and moved separately with each other. Thereafter apyrene sperm preceded in the pathway of the female reproductive organs. The cyst wall of eupyrene sperm bundles became loose during the passage through the vas deference and the mass of eupyrene sperm was transferred to the bursa copulatrix about 40 minutes after mating. About 6 hours after mating only apyrene sperm appeared in the spermatheca (legena receptaculi) and eupyrene sperm followed them 1 hour later. The latter were deprived of their sheath. The adult female began oviposition at the next day after mating. Such a time lag of passage between eupyrene and apyrene sperm observed in *Atrophaneura alcinous* is characteristic among Papilionidae species. Our observation suggests that apyrene sperm play a role as pilots to assist the transfer of eupyrene sperm.

03-037

SPERMATOGENESIS OF DIAPAUSE AND NON-DIAPAUSE PUPA IN THE SWEET POTATO HORNWORM, *AGRIUS CONVULVULI* (L.) (LEPIDOPTERA: SPHINGIDAE).

M.Shimoda, M.Kubo-Irie¹, H.Mohri²

Department of Insect Genetics and Breeding, National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan -1 University of The Air, Mihama-ku, Chiba, Japan -2National Institute for Basic Biology, Myodaiji-cho, Okazaki, Japan

Spermatogenesis was investigated in both diapause and non-diapause individuals of *Agrius convolvuli*. To determine the timetable of spermatogenesis, testes were dissected out from larva, pupa and adult, and observed under the optical microscope after vital staining with fluorescent dye and under the electron-microscope after ultrathinsectioning. Spermatocytes destined to either nucleate (eupyrene) or anucleate (apyrene) spermatozoa were recognizable in the testis of 5th instar larva.

In non-diapause individuals, larvae were reared at 25°C and 16L-8D photoperiod; their pupal stage extended for 15 days at 25°C and 12L-12D photoperiod. The eupyrene metaphases were seen during fifth instar larvae and lasted until about day-5 pupae. The earliest spermatids appeared in day-2 wandering larvae, about 3 days before pupation, however, the nuclei of these spermatids started elongation after pupation. The eupyrene spermatids with elongated nuclei, nearly mature sperm bundles, appeared at the day of pupation. The apyrene spermatocytes were seen during fifth instar larvae, and early apyrene spermatids appeared only after pupation. On the other hand, diapause was induced by rearing at 23°C and 12L-12D photoperiod; their pupae remained in diapause for 121 ± 38 days at 25°C and 12L-12D photoperiod. The timetable of the early stages of spermatogenesis was almost similar to that found in non-diapause ones. But the eupyrene metaphases continued to appear uninterruptedly throughout diapause. The eupyrene spermatids with both spherical nuclei and elongating nuclei were also seen in the diapause pupae, and the sperm bundles almost disappeared 40-60 days after pupation. In testes of diapause pupae, spermatocytes were conspicuously characterized by degenerating structures of mitochondria losing cristae, small lobed cytoplasm and concentric layers of endoplasmic reticulum around the nucleus.

03-039

SPERM RELEASE BY AN INTRATESTICULAR MUSCULAR MECHANISM IN THE TROGID BEETLE *OMORGUS FREYI*

M. Friedländer, R. Eren-Jeger and C. H. Scholtz*

Life Sciences Department., Ben Gurion University, Beer Sheva, Israel and *Zoology Department, Pretoria University, Pretoria, South Africa.

Desert beetles of the genus *Omorgus* display an unique mechanism of sperm release involving intratesticular visceral muscles. Like in other insects, the testes are made of finger-like follicles containing clusters of spermatogenic cells that develop synchronously; each cluster is confined within a cyst. However, in contrast with follicles of other insects, those of *Omorgus* are subdivided into sectors by radial cellular septa converging into a centrally located vas efferens. In transverse sections, they resemble oranges sliced through their equatorial plane. Further, an extended net of myofibrils surrounds the cysts, runs within the septa and attaches to vas efferens and follicular walls. Apparently, during *Omorgus* phylogenesis, the vas efferens changed its position from outside to inside the follicle. Accordingly, the myofibril net may derive from the muscular system of the intra-follicular vas efferens. In a typical follicle, sperm release is related to pressure exerted by new cysts generated at its distal end. Appearance of the novel muscular mechanism may be related to the disproportionately large size of *Omorgus* follicles; the pressure would be insufficient for sperm release if the vas efferens remained outside the follicle.

03-040

THE DORSAL VESSEL OF INSECTS: MORPHOLOGICAL SOLUTIONS TO CIRCULATORY PROBLEMS.

T. A. Miller

Department of Entomology, University of California, Riverside, CA USA

Insects have an open circulatory system and the hemolymph is not needed to transport oxygen. Nevertheless, it is vital that the hemolymph reach all of the tissues of the enveloping epidermis and internal organs and tissues. To accomplish this task in the extremities, insects have evolved ingenious specializations reported by others in this symposium. However, there are major specializations of structures in the main part of the abdomen of orthopteroid insects to ensure local circulation in the perineural and pericardial sinuses. Two very different types of these specializations have evolved in locust and cockroach to accomplish local circulation that make the cardiac physiology of locust and cockroach unique. Similar specializations in other insects have not been studied in the same detail, but are equally as important.

03-042

STRUCTURE AND FUNCTION OF THE ANTENNA-HEART OF *PERIPLANETA AMERICANA*

W. Hertel, H. Agricola

Institut für Allgemeine Zoologie und Tierphysiologie, Friedrich-Schiller-Universität Jena, Germany

In insects, specially accessory pulsatile organs were developed for supplying the antennae with haemolymph. The best investigated one is the antenna-heart of *P. americana*.

A transverse muscle band connects the two ampullae, which are dilated by contracting of this muscle. The rhythm of this dilator muscle is caused by a myogenic automatism and is influenced neuronally via the nervus cardioantennalis. All muscle fibres cover the whole muscle and branch at the ends near the ampullae. Intercalated discs are missing, but the fibres are electrically coupled with an appropriate coupling coefficient. Extensively branched muscle fibres of an accessory dilator muscle are integrated in the transverse muscle. All muscle fibres revealed similar electrical properties. Electrical stimulation of the antenna-heart nerve resulted in a complex effect: a transient heart block followed by an increase in the heart beat rate. The acceleration is caused by the peptide transmitter proctolin, shown (see below) and detected biochemically. Octopamine is the inhibitory neuromediator in the antenna-heart.

Furthermore, by means of the immunofluorescence technique the biogenic amines octopamine and 5-HT as well as the insect neuropeptides proctolin and allatostatin could be shown in the antenna-heart. Colocalization of proctolin and allatostatin proved in the antenna-heart as well as in the suboesophageal ganglion (SOG) and Co^{2+} -backfills of the antenna-heart nerve suggest the SOG to be the source of this immunoreactivities.

03-041

IDENTIFIED NEURONES INNERVATING THE HEART OF INSECTS

P. Bräunig

Institut f. Zoologie, Technische Universität München, Garching, Germany

The number of identified insect neurones involved in the generation of behaviours such as flight, walking, respiration and stridulation, as well as neurones involved in sensory integration of visual, acoustic, olfactory and mechanical stimuli has grown so enormously that databases, or at least unified rules for labelling individual cells are urgently needed. This situation is contrasted by the fact that only very little is known about neurones innervating insect visceral organs such as heart, gut and glands. Although it has been known for a long time that the heart of insects receives innervation from either the retrocerebral glandular complex and/or segmental heart nerves from abdominal ganglia, the neurones forming these nerves are yet unknown in most insect species. Only recently some progress has been made for at least one insect species, the migratory locust. Quite a number of neurones have been identified individually which innervate the heart in these insects. The neurones show a wide spectrum of morphological and neurochemical characteristics, and almost each ganglion of the ventral nerve cord appears to contribute to the innervation of the heart.

03-043

WING CIRCULATORY ORGANS OF INSECTS - MORPHOLOGY AND EVOLUTION

H.W. KRENN, G. PASS

Institute of Zoology, University of Vienna, Austria

In addition to the dorsal vessel, insects possess auxiliary pumps for hemolymph supply of body appendages. The accessory pulsatile organs for hemolymph transport in the wings are located beneath the tergite of each winged segment. They suck hemolymph from the posterior wing veins through cuticular tubes running along the tergites. All wing circulatory organs consist of a pump casing, formed by the scutellum, and an associated myofibrillar pulsatile component.

The comparative investigation of more than 100 species from almost all insect orders revealed a remarkable diversity in the anatomy of the pulsatile components. They can be formed either by modifications of the dorsal vessel or by muscular diaphragms which are attached to, or separate from, the dorsal vessel. In several lineages of Holometabola convergent evolutionary trends can be reconstructed leading from dorsal vessel modifications to separate unpaired or paired pulsatile diaphragms ("wing-hearts"). There is strong evidence that the pulsatile diaphragms are individualized parts of the dorsal vessel wall. The diversity and systematical distribution of wing circulatory organs in Lepidoptera allows the reconstruction of the transformation from attached diaphragms to separate wing-hearts without postulating intermediate states of uncertain functionality.

The results lead to a new interpretation of the evolution of the circulatory organs in the thorax. Spatial constraints resulting from modifications of the flight apparatus are discussed as possible causes for the multiple parallel evolution of wing-hearts.

03-044

HOW OTHER MEMBERS OF THE FAMILY TRANSPORT SOLUTES - FUNCTIONAL MORPHOLOGY AND PHYSIOLOGY OF THE CIRCULATORY SYSTEM OF SPIDERS

R. J. Paul

Institut für Zoophysiologie, Westfälische Wilhelms-Universität
Münster, Germany

The circulatory system of most spiders consists of the heart, pericardium, arterial vascular system, the open venous system, and lung veins connecting book lungs to the pericardium. Morphological details of the heart and pericardium allow them to function co-operatively as a pressure-and-suction pump, which generates a continuous perfusion of the book lungs both during systole and diastole. The arterial vascular system and the venous open system show adaptations to cellular oxygen requirements. At least in the legs, capillarization is absent and gas exchange with the tissues has to take place primarily along the open portion of the circulatory system. The high pressure generated in the prosoma during locomotor activity is not transmitted to the opisthosoma. A neuronally controlled occlusion mechanism (muscular valve) at the anterior end of the pedicel is most likely responsible for the maintenance of this large pressure gradient. The prosomal perfusion is interrupted during fast locomotion, the opisthosomal perfusion is maintained. Cardiac output in the tarantula can be increased by two mechanisms: increase of stroke volume and increase of heart frequency. Both are related to an increase of heart pressure. Especially during the early phase of recovery from fast locomotion, there are changes in blood flow distribution. A larger share of blood is pumped to the prosoma. The underlying mechanism could be a neuronal control of the cardio-arterial valves of the opisthosomal lateral arteries.

03-046

HEARTBEAT AND REVERSAL OF HEARTBEAT DIRECTION INTERACTS WITH DISCONTINUOUS CARBON-DIOXIDE RELEASE IN RESTING PAPILIONID-PUPAE

S.K. Hetz¹, L.T. Wasserthal²¹Department of Animal Physiology, Humboldt-University at Berlin, Germany²Institute of Zoology I, University of Erlangen, Germany

In non-diapausing pupae of the papilionid species *Troides rhadamantus* and *Ornithoptera priamus* (Lepidoptera, Papilionidae) within the initial half of development, discontinuous carbon-dioxide release was found to occur at the same time when heartbeat direction changes from backward pulsations to forward pulsations.

Heartbeat patterns consisted of continuous forward-pulse periods, continuous backward-pulse periods and intermittent backward-pulse periods when heartbeat and heartbeat-pauses alternated.

Thermo-anemometric, infrared-optic and ultrasonic-doppler studies indicated that the haemolymph transport in anterior direction is more effective than in posterior direction. This is due to the higher heartbeat-frequency and heartbeat-amplitude of the forward-pulsations.

A possible role of the interaction between heartbeat-reversal and carbon-dioxide release can be found in the more effective mixing of the haemo-lymph during forward-pulsations. This convective mixing shortens the diffusion pathway of carbon-dioxide within the haemolymph and so facilitates the carbon-dioxide transfer from haemocoel into tracheal space.

DISCONTINUOUS CIRCULATION AND ITS EFFECT UPON TRACHEAL VENTILATION IN ADULT INSECTS AND THE STRUCTURAL ADAPTATIONS.

L.T. Wasserthal

Institut für Zoologie I, Staudtstr. 5, D-91058 Erlangen, Germany

In resting adult insects (Lepidoptera, Coleoptera, Diptera and Hymenoptera) hemolymph oscillates between anterior body and posterior body, due to its internal partitioning and discontinuous heartbeat activity (periodic heartbeat reversal and/or heartbeat pauses combined with discontinuous backward flow in the perineural sinus). Heart ostia and partitioning structures behind the waist are adapted to this mechanism in different ways within different insect orders. The relatively uncomplicated circulation mechanism of higher flies with a dominant central heart chamber contrasts to the mechanism in moths where three pumping organ systems (abdomen wall, heart and accessory pulsatile organs) work in a hierarchical order. While in the resting and running blowfly air sac ventilation is driven mainly by periodic hemolymph shift alternately in anterior body and abdomen due to heartbeat reversal, in various insects intermittent abdominal pumping movements are performed and are coordinated with specific phases of the heartbeat periodicity, most frequently coinciding with the moment of maximum hemolymph accumulation in the abdomen.

03-047

CARDIAC AND RESPIRATORY ACTIVITIES IN THE ADULT FLY, *PROTOPHORMIA TERRAENOVAE*

A.M. Angioy, P. Muroi, N. Piroddi, I. Tomassini Barbarossa

Dipartimento di Biologia Sperimentale - Sezione di Fisiologia Generale, Università degli Studi di Cagliari, Cagliari, Italia

In adult flies, cardiac activity consists of the regular alternance of a fast phase with a slow phase, at higher and lower beating frequency respectively. A periodical inversion in the direction of haemolymph flow corresponds to phase alternance, which is thought to play an essential role in tracheal ventilation. In this study we analyzed electrocardiographic activity in intact and semi-intact preparations, to determine the most significant heart activity parameters in adult flies. We also attempted to see if any relationships exist between cardiac and respiratory activities. To this end, heart activity and endotracheal pressure were simultaneously monitored on intact specimen by means of electrophysiological and piezoelectrical techniques respectively. Changes in abdominal sizes during regular heart cycles were also measured by means of a computerized image analyzer system. Results showed that bioelectric heart activity consists of impulses propagating forwards along the vessel during the fast phase and backward during the slow phase. Consequently, haemolymph flows towards the head during the fast phase and towards the abdomen during the slow phase. Cardiac and respiratory activities are closely related, showing cyclic synchronous time courses. A deep inspiration occurs simultaneously with an abdominal expansion, which takes place just before the beginning of a fast phase. A profound expiration occurs simultaneously with an abdominal retraction, which takes place immediately before the beginning of a slow phase. Inspirations and expirations are followed by a return of thoraco-cephalic air pressure to the atmospheric value during the forward and backward beating of the heart respectively.

MORPHOLOGY, PHYSIOLOGY, AND PEPTIDERGIC REGULATION OF THE HEART OF THE TOBACCO HAWKMOTH *MANDUCA SEXTA*.

N.J. Tublitz and G.R. Huesmann

Institute of Neuroscience, University of Oregon, Eugene OR USA 97403

The heart of the tobacco hawkmoth *Manduca sexta* plays a number of critical roles during the life cycle of this organism. In addition to its obvious circulatory function, the heart is intimately involved in thermoregulation, wing inflation, and flight. In this talk I will discuss several aspects of cardiac structure and function in this species, focussing on the morphology and physiology of the adult heart and its control by neuropeptides.

03-050

THE SPATIAL ORGANIZATION OF DIGESTION IN INSECTS

Walter R. Terra

Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, São Paulo, Brazil.

Digestive enzymes were assayed in materials derived from midgut cells and from the spaces outside and inside the peritrophic membrane (PM) from insects of different orders. Moreover, midgut fluid fluxes were studied using dyes. The data showed that in lower insects most digestion occurs inside the PM, whereas in more evolved insects only the initial stage of digestion occurs there; intermediate and final stages take place in the space outside PM or at the midgut cell surface. Most insects present a countercurrent flux of fluid outside PM which powers digestive enzyme recycling. Hemiptera insects differ from the main evolutionary stream. These insects lack a PM and their midgut cell microvilli are ensheathed by an outer lipoprotein membrane (perimicrovillar membrane, PMV). These membranes (isolated by gradient ultracentrifugation) have low density (1.087 g/cm³) and lipid content (1090 µg lipid/ mg protein), which is close to what is found in myelin sheaths. α-Glucosidase is bound to the PMV in *Dysdercus peruvianus*, and was purified to homogeneity. Immunocytochemical localization of α-glucosidase in *D. peruvianus* midgut cells showed that PMV originate from double membrane vesicles budded from differentiated Golgi areas. These results, along with digestive enzyme compartmentalization data, suggested that PMV evolved in plant sap-sucking Hemiptera ancestors as a structure to permit the absorption of amino acids present at low concentration in sap. In evolved Hemiptera displaying luminal digestion (seed- and blood-feeders), PMV compartmentalizes digestive events as PM in other insects.

WATER CIRCULATION IN THE HONEY BEEK. Crailsheim¹, K. Visscher², G. Sherman²

(1) Institut für Zoologie an der Karl Franzens-Universität A-8010 Graz, Universitätsplatz 2, Austria

(2) Department of Entomology, University of California, Riverside, CA

The volume of a honey bee's haemolymph can vary between 11 and 20 µl. Soon after the injection of a radioactive tracer (polyethylene glycol) into the haemolymph, the tracer can be found equally distributed within the haemolymph, indicating a rapid mixing (Crailsheim 1985, J. Insect Physiol. 31: 707-713).

Usually the crop of a honey bee contains concentrated sugar solutions. This food is transported through the proventriculus into the midgut in response to the actual metabolic need (Crailsheim 1988, J. Insect Physiol. 34: 85-90). Sugar and water are absorbed very quickly from the midgut (Crailsheim 1988, J. Insect Physiol. 34: 839-845).

We studied bees collecting water (for thermoregulation and to maintain high hive humidity for brood rearing) over long distances in a desert. Returning water foragers had crops full of water, with almost no sugar. When a water forager must fly for a long time before reentering the colony, water, instead of sugar, enters the midgut when the proventriculus opens. When this happens, bees absorb about one quarter their own weight in water, and excrete most of it within about 20 minutes. In this time they exchange a volume of water at least as large as that of their entire haemolymph.

03-051

THE MIDGUT AS A COORDINATED EPITHELIUM

P. F. Billingsley

Department of Zoology, University of Aberdeen, Tillydrone Avenue, Aberdeen, AB9 2TN, Scotland, U. K.

The insect midgut must respond to the ingestion of food by secretion of digestive enzymes and initiation of absorptive processes. In insects that feed continuously, there is little evidence for a co-ordinated response to the diet. However, in the intermittent feeders, in particular the haematophagous species, the cellular responses to ingestion are predictable co-ordinated both spatially and temporally. This co-ordination is also evident in the secretagogue response, where enzymes are produced according to the quality and quantity of the diet.

This presentation will provide an overview of processes in the insect midgut that can provide evidence for the insect midgut epithelium acting in a co-ordinated manner to initiate synthesis and secretion of digestive enzymes and peritrophic matrix, and absorption of dietary and digestive products. The overview will suggest mechanisms by which such co-ordination and control can occur, and highlight some areas where further research is clearly necessary.

03-052

CELL DIFFERENTIATION IN THE *MANDUCA* MIDGUT EPITHELIUMK.M. Baldwin¹, R.S. Hakim^{1,2}, M.J. Loeb² and S. Sadrud-Din^{1,2}¹Department of Anatomy, Howard University, Washington, DC USA²Insect Neurobiology and Hormone laboratory, USDA, Beltsville, MD USA

In the larval *Manduca sexta* midgut epithelium, undifferentiated stem cells proliferate prior to the molt and then differentiate to become goblet or columnar (absorptive) cells during the molt. Cell differentiation follows the pattern seen in the embryo, except that the newly differentiated cells are intercalated among mature larval cells. A distinctive cell pattern is observed in both embryos and larvae. Single goblet cells are surrounded by a one-cell-thick reticulum of 3-6 columnar cells. This pattern is observed as soon as the two cell types can be identified. Establishment of such a pattern requires some type of cell signalling. The dye Lucifer yellow will not transfer between larval midgut epithelial cells during the intermolt periods, but the cells become dye-coupled temporarily at the time the pattern is established in the newly differentiating cells. Thus, the signal for pattern formation could be passed through gap junctions. To study the effects of gap junctions on cell patterning, we have begun to isolate the gap junction protein from larval midgut epithelium. Fractions highly enriched in both gap and septate junctions are also enriched in proteins of 80 kDa and 95 kDa. Preliminary data suggest that the gap junction protein is 80 kDa. Cultures of larval midgut epithelial cells have been developed to study controls on cell proliferation and differentiation. Stem cells will proliferate in culture in the presence of 20 hydroxyecdysone and fat body extract. Stem cell differentiation in cultures only occurs in the presence of a factor produced by the mature larval cells.

03-054

CHARACTERISATION OF PERITROPHIC MEMBRANE PROTEINS FROM THE LARVAE OF *LUCILIA CUPRINA*
 R. L. Tellam, C. Elvin, R. Casu, C. Eisemann and S. Schorderet
 CSIRO Div. Trop. Animal Prod., Indooroopilly, Queensland, Australia

The peritrophic membrane (PM) is a semi-permeable chitinous matrix lining the gut of most insects and is thought to have important roles in the maintenance of insect gut structure, the facilitation of digestion and protection from invasion by microorganisms and parasites. Proteins are integral components of this matrix although the structures and functions of these proteins have not been characterised in any detail.

The PM from the larvae of the fly *Lucilia cuprina*, the primary agent of cutaneous myiasis in sheep, was shown to contain 6 major integral PM glycoproteins, two of which together represent >70 % of the total mass of the integral PM proteins. The cDNAs coding for 3 of these proteins were cloned and sequenced. The deduced amino acid sequences indicated that each of these proteins contain 5 similar, but non-identical domains, each of ~ 70 amino acids and characterised by a specific register of 6 cysteines. One of these domains was also present in the non-catalytic regions of chitinases from *Brugia malayi*, *Manduca sexta* and *Chelonus*. There was a uniform distribution of these proteins throughout the PM. RT-PCR indicated that the PM proteins were primarily expressed in larvae and were synthesised by cells in the cardia. One of these proteins, peritrophin-44, binds reacylated chitosan and tri-N-acetyl chitotriose in vitro suggesting that these proteins bind directly to chitin fibrils within the PM. Antibodies to each of these proteins, when fed to larvae, inhibited the growth of the larvae by a common mechanism which involved the blockage of the pores in the PM and the subsequent starvation of the larvae. These results indicated that PM proteins play a key role in the maintenance of PM structure and in the determination of the porosity of the PM. Furthermore, it was demonstrated that PM proteins are effective targets for immunological control of the growth of these larvae.

03-053

DEVELOPMENT OF A POLARIZED EPITHELIUM: THE V-ATPASE AS A MEMBRANE MARKER IN THE MOULTING MIDGUT OF *MANDUCA SEXTA*.

U. Klein, D. Jaeger

Zoologisches Institut der Universität, München, Germany.

For our study on differentiation of epithelial cells and the biosynthesis of domain-specific membrane proteins we make use of the moulting midgut of larval *Manduca sexta*. During the moults unpolar stem cells proliferate and differentiate into mature columnar or goblet cells (Baldwin and Hakim 1991, Tissue & Cell 23, 411). The plasma membrane V-ATPase is the primary ion pump that energizes epithelial transport; it is localized only in the goblet cell apical membrane and may serve as a membrane marker. We now investigated the spatial and temporal distribution of the V-ATPase and its mRNA during moult by immunocytochemistry and *in situ* hybridization (Jaeger et al. 1996, J exp Biol, in press).

In mature goblet cells, immunoreactivity of the apical membrane is lost during moulting but re-appears shortly before ecdysis; this is due to dissociation of subunits of the peripheral V₁ sector from the membrane V₀ sector (Sumner et al. 1995, J Biol Chem 270, 5649). The mechanism of reconstitution, either by re-assembly of old or new V₁ sectors from the cytosol or by complete turnover, is not yet known. Slightly increased mRNA signal in mid-moult found for a V₁ subunit in mature goblet cells, points to enhanced biosynthesis. In differentiating goblet cells, the endosomal goblet cavity precursor compartment (GCPC) gains immunoreactivity in late moult. The V-ATPase signal of this membrane increases in intensity and area after fusion of the GCPC with the apical domain. Therefore, the V-ATPase is sorted into a membrane which changes its domain status and, thus, may not keep its target definition. Surprisingly, considerable mRNA-labelling was found in both mature cell types and in all proliferating cells from the beginning. In columnar cells, however, immunolabelling is found only transiently in the cytosol of the mature cells in apically secreted cell portions. To approach the problem of V-ATPase sorting and assembly, we currently investigate the effects of cycloheximide and brefeldin A, inhibitors of the biosynthetic pathway.

VECTOR PARASITE INTERACTIONS IN THE INSECT MIDGUT

Susan C. Welburn and David C. Kaslow¹. Division of Molecular Genetics, Institute of Biomedical and Life Sciences, University of Glasgow, Anderson College, 56 Dumbarton Road, Glasgow, G11 6NU, U.K. ¹ Molecular Vaccine Section, LMR, NIAID, National Institutes of Health, Bethesda, MD 20892, USA.

It has been generally assumed that the insect plays a largely passive role in the vector parasite relationship to the extent that in many cases vectors of parasitic disease are regarded only as a 'flying syringes'. It is becoming increasingly clear that insects and the parasites they transmit have a far more intimate relationship especially in the insect midgut.

In the cases of malaria and leishmania the parasites have evoked the use of an enzyme (chitinase) at different points in their life cycles to penetrate the chitinous tissue of the vector and facilitate transmission. Some insects (for example tsetse) have evolved efficient sugar dependant systems to recognise and destroy incoming parasites; parasites which evade this primary defence utilise the same host molecules as signals for their differentiation and subsequent 'exit' from the vector. In tsetse lectins secreted in the insect midgut control both establishment of the parasite infection (signalling cell death) and conversely also appear to be essential for trypanosome migration from the midgut and subsequent development to mammalian infective form (signalling maturation). These examples raise important considerations concerning the nature of the host parasite interface - it is in the parasite and vectors best interests that infections are maintained in a controlled manner and for as long as possible within the insect.

03-056

PUTATIVE ENDOCRINE CELLS IN THE OPAQUE ZONE OF *STOMOXYS CALCITRANS* (DIPTERA: MUSCIDAE)
R. Bastow, W. Mordue
Department of Zoology, University of Aberdeen, Tillydrone Avenue, Aberdeen, AB9 2TN, UK

Cell bodies are present in the opaque zone of sugar fed *Stomoxys calcitrans* which are immunoreactive to the vertebrate opioid β -Endorphin. Cells resembling endocrine cells of the vertebrate gastrointestinal tract are present in the midgut of *Stomoxys calcitrans*. At the ultrastructural level, endocrine-like cells are seen in close association with epithelia which synthesise and release proteases in the opaque zone of *Stomoxys calcitrans*. In an attempt to understand the role of these peptide-containing cells in the digestive physiology of the insect, the intention is to investigate any correlation between changing intracellular concentrations of peptides and proteases during processing of the blood meal. This will include further double immunolabelling of β -Endorphin immunoreactive material and trypsin-like enzyme in the opaque zone and the development of a suitable competitive ELISA to measure changing concentrations of β -Endorphin immunoreactive material. Immunoreactive peptide/peptides will be further characterised by use of HPLC analytical methods.

03-058

MECHANISMS OF TRYPSIN SECRETION
B. P. Jordão
Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, São Paulo, Brazil.

Trypsin secretion was verified in two Diptera Muscidae species using immunocytochemical techniques. The bacteria-feeding *Musca domestica* larvae do not accumulate secretory vesicles in their midgut cells and trypsin produced is fully active, unlike the blood-feeding *Stomoxys calcitrans* flies, which accumulate numerous secretory granules in a specialized midgut region (opaque zone), that are released upon stimulation, and trypsin produced is activated only when in the gut lumen. Biochemical data indicate *M. domestica* soluble trypsin is derived from an intracellular membrane form. The data indicate that *M. domestica* trypsin is secreted via an exocytic route of discharge of secretory vesicles. Inside these vesicles, trypsin was immunolocalized on the membrane. Membrane trypsin is not affected by papain or phosphatidylinositol-specific phospholipase C; is similarly solubilized by detergents with high or low critical micellar concentrations; solubilization increases at high pH values in the presence or absence of detergent. Solubilized membrane-trypsin behaves as a hydrophilic protein. The data suggest that trypsin is bound to the secretory vesicle membrane by a hydrophobic peptide anchor. Upon exocytosis, trypsin solubilization must occur because the neutral luminal pH causes a conformational change which hinders part of the trypsin anchor. Attaching trypsin to vesicle membrane may represent the insect's strategy to protect midgut cells from proteolytic damage in the absence of zymogens. Opaque zone secretory granules were heavily stained for trypsin both in unfed and blood-fed *S. calcitrans* flies. Heterogeneity in labelling intensity in different granules from a single cell and the appearance of new small and heavily stained granules, close to the apical membrane in fed flies, suggest the occurrence of preferential release of newly-synthesized granules, and possibly of non-parallel secretion. Trypsin-stained intact secretory granules and cell debris were found in the ectoperitrophic space of the opaque and lipid zones of blood-fed flies, supporting the assumption that some trypsin is released by apocrine means. Our data indicate trypsin secretion in *S. calcitrans* flies occur mainly by the classical exocytic route. The minor amount of trypsin secreted by apocrine means could represent a way of rapidly releasing enzyme soon after a blood meal is taken. Supported by: FAPESP, CNPq and British Council.

MICROVILLAR MEMBRANES FROM MIDGUT CELLS
Clélia Ferreira
Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, São Paulo, Brasil.

Although the midgut microvillar membranes seem to be important in terminal digestion, little is known about their chemical composition. By differential precipitations, we isolated microvilli from different midgut regions of larvae of *Tenebrio molitor* (Coleoptera), *Rhynchosciara americana* (lower Diptera), *Musca Domestica* (higher Diptera) and *Spodoptera frugiperda* (Lepidoptera). The microvillar preparations were treated with hyperosmotic Tris buffer, then diluted, centrifuged, and the purified microvillar membranes were recovered from the resultant pellets. Specific activities of marker enzymes in purified membranes were 1.5-3.0-fold higher than in the original microvillar preparations, except for the membranes from the anterior midgut of Lepidoptera, where no enrichment was achieved. The final yield was about 20% in all preparations. Contamination by soluble proteins was under 0.3%, and by other membranes never exceeded 5% ,as judged by chromatography in Sepharose 4B and/or by sucrose gradient ultracentrifugation. The microvillar membrane from posterior midgut of Lepidoptera was contaminated by glycogen, which can also be seen on electron micrographs. In comparison with mammals, insect membranes are rich in carbohydrates (all insects except *S. frugiperda*), cholesterol (*T. molitor*), lipids (*T. molitor*), and proteins (*M. domestica* and *S. frugiperda*). Our results suggest that the initial microvilli preparation of *S. frugiperda* anterior midgut are isolated with no cytoskeleton contaminants, needing no further purification steps. They also suggest that the amount of protein found in the microvillar membranes depends on the phylogenetic position of the insect and, along the midgut, on the amount of membrane bound enzymes or membrane bound transporters. Supported by FAPESP and CNPq.

CHEMORECEPTORS OF THE POTATO TUBER MOTH,
PHTHORIMAEA OPERCULELLA ZELL. (LEPIDOPTERA
GELECHIIDAE).

Aziza Sharaby¹, M.M. El-Missiry², S. Abdel-Hamed³
^{1,3} Pests and Plant Protection Department,
National Research Centre, Dokki, Cairo, Egypt.
² Pharmaceutical sciences Department, National
Research Centre, Dokki, Cairo, Egypt.

Description and distribution of moth chemoreceptors on different body appendages by the use of optical and scanning electron microscopes, revealed present of :

1. Antenal chemoreceptors: Include sensilla trichodea (types a and b), sensilla chaetica and sensilla coeloconica.
2. Proboscis chemoreceptors: The apical region bears sensilla chaetica at its apex and rasp-like structure along its length, while the distal region bears two types of sensilla styloconica, among which are found sensilla trichodea and sensilla chaetica.
3. Tarsal chemoreceptors: Include one type of sensilla in the form of curved sensilla trichodea (type b) on the different tarsal segments and the two pulvilli that bear various sensilla including macrotrichodea, chaetica and chemoreceptor setae.
4. The ovipositor lobes: Bear mechanoreceptor and chemoreceptor sensilla, in the form of trichoid sensilla (types a and b) and 5-6 macrotrichodea.
5. The male copulatory organs: (represented by two harps and anal papillae) bear different receptors in the form of sensilla trichodea pheromonal receptors (acted in S. trichodea, type b) and pegs on the two harps, and numerous numbers of sensilla styloconica on the two anal papillae.

03-061

STRUCTURE AND DEVELOPMENT OF THE INTERNAL REPRODUCTIVE SYSTEM OF *APHELOCHEIRUS AESTIVALIS* (F.) (HETEROPTERA: APHELOCHEIRIDAE)

M. Papáček, T. Soldán¹

Pedagogical Faculty, University of South Bohemia, České Budějovice, Czech Republic - ¹ Institute of Entomology, Academy of Sciences, České Budějovice, Czech Republic

The histological structures and morphological arrangement of male and female internal reproductive system of *A. aestivalis* have been studied in nymphs of instars 1-5 and variously aged apterous adults. The anlagen of gonads are well apparent in the first instar, differentiation of testicular follicles and ovarioles starts in the instar 2 and is finished in the 3rd instar. Two pairs of the accessory mesadenia are differentiated in the same way. Morphological differentiation among germ cells descendants happens during the late instar 4 and instar 5 as well as formation of the germinal trophic core from a membrane labyrinth in females. Vitellogenesis is started before imaginal moulting.

The timing of crucial reproductive processes in *A. aestivalis* seems to be rather different from the situation in most of other aquatic Heteroptera. For instance, the evidently permanent, spring to autumn gradual, multi-waved spermatogenesis and the presence of mature sperm in spermatheca of teneral, newly hatched females indicate possible semivoltinism as far as the life cycle is concerned.

03-060

MOUTHPARTS MORPHOLOGY OF A CARNIVOROUS MAYFLY, *MIRAWARA MEGALOPREPIA* RIEK (EPHEMEROPTERA: AMELETOPSIDAE)

T. Soldán¹ and M. Putz²

¹Institute of Entomology, Academy of Sciences of the Czech Republic, České Budějovice Czech Republic - ²Biological Faculty, South Bohemian University, Czech Republic

The morphology of fully-grown larvae of *M. megaloprepia* was studied with emphasis to its carnivorous habits. Contrary to most other mayfly larvae which are collectors, scrapers or unspecialized shredders the mouthparts of *M. megaloprepia* are highly specialized to engulfing the whole benthic animals. Labrum is large provided with stout spines on the ventral surface, covering all the remaining mouthparts; Maxilla with considerably reduced molar part and conspicuous movable teeth with membranous base; both maxillary and labial pales are uniquely multi-segmented; hypopharyngeal superlinguae strongly reduced. A lot of types of strong seatac and spines specialized for grasping the prey are described not only on mouthparts but also on the fore legs. All the mouthparts are very flexible at their bases. Epipharyngeal area can be enormously widened. Proctodcum forms a membranous retractile crop. The relationships between this mouthpart arrangement and other types occurring in mayflies are discussed with regard to ecological and phylogenetic aspects.

03-062

MORPHOLOGICAL STRUCTURES OF THE OVIPOSITOR IN THE EULOPHINAE (HYMENOPTERA: EULOPHIDAE)

Zoya A. Yefremova

Department of Zoology, Ulyanovsk State Pedagogical University, Russia

Morphology of the eulophin ovipositor is studied basing mainly on palaearctic material. Sclerites of the ovipositor (gonapophysis, gonostyl, gonocoxite), their shape, junction, apodemes and various sensillae on these sclerites are described for the Eulophinae for the first time and coeloconic sensillae were found on the sclerites also for the first time.

The research showed that different tribes of the Eulophinae have various structures and their junction. The analysis of evolutionary transformations of gonostyl and gonocoxite are presented in eulophin groundplan where gonostyl has numerous trichoid sensillae. That ovipositor is used for puncture of leaf-vein Lepidoptera. Another morphological modification is represented by a complete knit of gonostyl and gonocoxite though gonostyl has lost all the sensillae. The intermediate type of the ovipositor has membranous junction of gonostyl and gonocoxite that has only trichoid sensillae. The ovipositor of the last 2 types inserts the eggs into integument of Noctuidae larvae. These evolutionary transformations are found as an adaptation to ovipositing on active living host. Those structures can be regarded as an apomorphic state and they are important for transferring those external parasites as are eulophids to new ecological niches.

03-063

THE SUBGENUAL ORGANS OF *LOCUSTA MIGRATORIA MANILENSIS* (May.)
B.X. Li, Y.Z. Lin¹
Department of Insect Ecology , Institute of Zoology, Chinese Academy of Sciences, Beijing, P. R. China -1 Department of Biology, Shandong Normal University, Ji'nan, Shandong, P. R. China

The structure of the subgenual organs in the for-, mid-, and hindleg of oriental migratory locust *locusta migratoria manilensis* was investigated in detail. In each leg the subgenual organs consist of two scolopale organs: the proximal and the distal organ. In the for-, mid-, and hindleg, the scolopidia of the subgenual organs are 42 , 38 , and 31 , that of proximal subgenual organs are 28 , 24 , and 20 , and in the distal organ, they are 14 , 14 and 11 . The morphology of the trachea in the mid- and hindleg is significantly different found that found the foreleg.

The location of the subgenual organs of locust is the same with that of the tibial tympanal organs of cricket and bush cricket that have the same innervation. The shape of the proximal organs is the same with just like that of the subgenual organs of the latter. The never 5B₁ and the tympanal never (TN) have the same origination. The arrangement of the scolopidia of the distal organ can comparably with those of the intermediate organs of cricket and bush intermediate organ and the crista acustica in Tettigoniodea and Grylloidea.

03-065

PHYLOGENETIC EXAMINATION OF THE SURFACE STRUCTURE AND ARRANGEMENT IN LEPIDOPTERAN SCALE(LEPIDOPTERA)
T.Shinkawa,T.Nakazawa
Biological Laboratory,The University of the Air, Mihama-Ku Wakaba,Chiba, Japan
Almost whole body of Lepidoptera is covered with scales differentiated into various patterns ranging from sensory hairs to ordinary scales.We carried out a comparative study using SEM on the surface structure of scales of various genera classified as Lepidoptera, which are distributed widely throughout the world. The relationship among the surface structures, the arrangement and color- patterns of scales was also examined. The surface structure of scales can be classified phylogenetically into several types. The arrangement of scales is closely related with these properties of scale.The stable color-patterns might be organized. This phylogenetic classification is applicable to every species of the order Lepidoptera.The surface structures of scales appears to be common in every species of each genus. Different structures of scales between each genus,however,suggest the phylogenetic development of scale and the specific evolution of cover scales causes a wide variety of color-patterns. The arrangement of scales also varies from a random arrangement to a concentric circular arrangement around the thorax. In conclusion there are five characteristics in these morphological development of scales.
1. There is no relationship between the color-pattern and the arrangement of scales on the wing surface.
2. The hairs are randomly positioned without any regularity and do not contribute formation of the color-pattern.
3. The arrangement of scales evolves in the concentric circles direction centering on the thorax.
4. The position and the arrangement of both hairs and scales are independent of each other.
5. In the group which has either pigment projections or random projection structures on the wing surface,the development of pigment projection and random projection structure is reversely proportional to the development of scale in that portion: as the structure develop,the scale degenerate.

03-064

EVOLUTIONARY TRENDS IN TACHINID EGG MORPHOLOGY (DIPTERA, TACHINIDAE)
S.P.Gaponov
Voronezh State University, 394000 Voronezh. RF.
I have studied the egg morphology of 112 species of 93 genera of tachinid-flies with different methods of egg-laying. In the egg structure of different groups morphological parallelisms (homoplasy) are widely spread. Within subfamilies Exoristinae (e.g. in tribes Blondelliini, Erycini), Tachininae and Phasiinae (in some groups of genera) there form eggs of transitory type, which combine features of macrotype and membranous eggs. The following transformations were noted in the egg structure of Tachinidae: 1) decrease of sizes and increase of a degree of incubation (microoviparian: Goniini); 2) increase of sizes as well as a degree of egg incubation (some Exoristinae, some Phasiinae, Voriinae, Dexiinae and Tachininae); 3) development of two aeropylar areas situated on the poles (usual) or egg sides (rare); 4) consolidation of cripts in the aeropylar zone (some Goniini, some Exoristini); 5) development of separated single aeropylar centre (some Goniini, macrooviparian Phasiinae); 6) division of the chorion into two parts: dorsal and ventral (microtype and most macrotype eggs); 7) melanization of the egg shell (Goniini); 8) there appears a devise for hatching and letting out of the 1st instar larvae: a) a lid of various structure; b) a coneshaped protuberance; c) an operculum; d) a belt of aeropylar cripts forming a seam (a-d - some Exoristinae); e) a longitudinal seams (some Phasiinae); f) a transversal seam (some Tachininae); 9) development of a plastron surface; 10) reduction of a plastron surface as well as respirative cripts (Tachininae, Dexiinae, some Exoristinae, some Phasiinae); 11) development of membranous chorion (ovolarviparian species); 12) thickening of the chorion (in eggs of microoviparian and most macrooviparian species); 13) get thin of the chorion (in eggs of most part of ovolarviparian species.

03-066

MORPHOLOGICAL ANALYSIS OF THE IMMATURE STAGES OF *SARCONESIA CHOROGASTER* (WIED.) (DIPTERA: CALLIPHORIDAE: TOXOTARSINAE)
S.R. Bonatto, C.J.B. de Carvalho
Departamento de Zoologia, Universidade Federal do Paraná, Curitiba, Paraná, Brasil
Sarconesia chlorogaster Wiedemann, 1830 is the only species of Toxotarsinae that occurs in Brazil, where it is limited to the southern region. This species has a high level of sinantropy and can be easily collected on decaying organic material.
From specimens reared under laboratory conditions on artificial oligidic diet, the external morphology of the egg and the immature stages (three larval instars and puparium) were described and illustrated. The cephalopharyngeal skeletons of the three larval instars were described and illustrated also.
The morphological analysis using the scanning electron microscopy showed details of unkown structures in the larvae: structure of the spines bands; presence of sensorial papillae in the oral region; presence of branched projections of the perispiracular glands; presence of a button in the base of the posterior spiracle; and in the puparium, the presence of a pair of respiratory horn.

03-067

THE IMPORTANCE OF MESOSCUTUM STRUCTURE IN TAXONOMY AND SYSTEMATICS OF THE HOVERFLIES (DIPTERA: SYRPHIDAE)

A. Vujić, M. Bokorov

Institute of Biology, University of Novi Sad, Novi Sad, Yugoslavia

In many recent papers which deal with taxonomic problems in the family of hoverflies one of character in use is the relief structure of mesoscutum. The authors make differences between some closely related species with type of puncturation: rough, dense, fine etc. The dusting and lustrous of mesoscutum are also often used characters.

In the analyses of mesoscutum scanning electron microscope JEOL-JSM 35 was used. Structure of sclerite surface in details is thoroughly studied in the species of three genera: *Cheilosia*, *Merodon* and *Paragus*.

Base on the results of the examination the estimation of the validity of mesoscutum characteristics used in taxonomy of the family is given. Status of couple of closely related taxa is elucidated. The differences in mesoscutum structure of springtime and summertime generations of a few species are studied. Finally, the potential significance of the examined structures in the systematics of the fly-group has been suggested.

03-068

OCCURRENCE AND ORIGIN OF PYGOPHORAL PARANDRIA IN THE PENTATOMOIDEA AND ARADOIDEA (HETEROPTERA)

J. Vilímová

Department of Zoology, Charles University, Prague, Czech Republic

Parandria - a pair of projections of pygophore, fixed or movable, cut off by a line of descle-rotization, with no associated musculature - are developed in three taxa, viz. Discocephalinae and Podopinae from the family Pentatomidae and family Aradidae. A gradual transformation series leading to development of parandria exists within the representatives of Aradidae. Parandria are always fixed firmly to the pygophore. Two pairs occur in some aradids. The pygophore of Discocephalinae bears never movable "posterolateral projections", delimited by a sulcus from the pygophore. *Podops* generic group (8 genera), tribe Podopini (Podopinae), has developed true parandria - movable, hollow lobes, connected by a membrane with the pygophore, and covering a large area of its dorsal surface. The parandria of such form represent an autapomorphic situation within the Pentatomoidea.

03-069

COMPARATIVE MORPHOLOGICAL STUDY OF LARVAL AND PUPAL STAGES OF *HELICOVERPA ARMIGERA* (Hb.) AND *HELIOTHIS PELITIGERA* (D. ET S.) (LEPIDOPTERA NOCTUIDAE HELIOTHINIINAE)

L. Sannino, B. Espinosa¹, P. Lombardi², A. Balbiani²
Istituto Sperimentale per il Tabacco di Scafati (SA), Italy - 1 Dipartimento di Entomologia e Zoologia Agraria, Università di Napoli, Portici, Italy - 2 Istituto Sperimentale per il Tabacco di Scafati (SA), Italy

Studies on the morphology of *Helicoverpa armigera* (Hb.) and *Heliothis peltigera* (D. et S.) were conducted at the Tobacco Experimental Institute by means of field and laboratory observations.

The new-born larvae show slight differences at pinacula, which in *armigera* are a little bigger than in *peltigera* and have, in L1 setae, the anterior margin flattened or concave, while it is always circular in *peltigera*.

In mature larvae the differences can be summarized as follows: a) the cuticular spinules of *peltigera* are of two different kinds - big, rare, of white colour, and little, dense, of black colour - while in *armigera* they are of one kind, short, squat and very close; b) spiracles are symmetric in *armigera* and slightly asymmetric in *peltigera*; c) the cuticular spinules of the big kind can be present on the pinacula of *peltigera*, while in *armigera* they are always absent.

Slight differences were found also in the pupal stage:

a) in *armigera* the portion of maxillae protruding over the mesothoracic legs is long about half the distance between the tips of antennae, but of almost equal length in *peltigera*; b) the cremaster in *armigera* is slightly prominent, with the basal tubercles of spines always present, while in *peltigera* the prominence is missing and the tubercles are only sketched

03-070

MORPHOLOGY OF THE QUITINIZED STRUCTURES OF MUSCIDAE SPERMATHECA (INSECTA: DIPTERA)

M. Couri

Departamento de Entomologia, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brasil

Little is known about the morphology of Muscidae (Diptera) spermatheca. Most papers illustrate only the capsule, which shape has little systematic significance when analyzed as a separate character. The observation of the quitinized structures of the spermatheca of some Muscidae species, made it possible to elucidate and understand characteres, which can be used in further phylogenetic analysis. 20 species of different sub-families were studied: *Biopyrellia bipuncta* (Wiedemann), 1830; *Musca domestica* Linnaeus, 1758; *Philornis univitattus* Dodge, 1968; *Charactrella malacophaga* Lopes, 1938; *Cyrtoneurina polystigma* (Wulp), 1896; *Neomuscina neosimilis* Snyder, 1949; *Brontaea debilis* (Williston), 1896; *Graphomyia mexicana* Giglio-Tos, 1893; *Mydaea plaumani* Snyder, 1941; *Scutellomusca marginata* (Albuquerque), 1954; *Dolicophaonia gallicola* (Albuquerque), 1958; *Phaonia nigriventris* (Albuquerque), 1954; *Limnophora saeva* (Wiedemann), 1830; *Coenosia camorinensis* Albuquerque, 1956; *Neodexiopsis paulistensis* Albuquerque, 1956; *Atherigona orientalis* Schiner, 1868; *Stomoxys calcitrans* (Linnaeus), 1758; *Muscina stabulans* (Fallén), 1817; *Ophyra solitaria* Albuquerque, 1958 and *Hydrotaea nicholsoni* Curran, 1939. The structures are very delicate, specially the spermathecal and expulsor ducts. No furca was observed. Two of the spermathecal ducts are fused just before entering the uterous. The following characteres and their states, were used to characterize species: 1. Shape of the capsule: round, pear-shaped or elongate; 2. Surface of the capsule: smooth to very rugose; 3. Pores at the capsule: absent or present (at base, apex or scattered); 4. Relative shape and size of the capsules: equal or different; 5. Spermathecal duct length: very short to very long; 6. Relative length of the spermathecal ducts: equal or one longer.

03-071

THE ULTRASTRUCTURE OF THE OUTER CHORIONIC SCULPTURING OF EGGS OF BRAZILIAN PHLEBOTOMINE SAND FLIES OF THE SUBGENUS *LUTZOMYIA* FRANÇA (DIPTERA: PSYCHODIDAE)

R. G. de Queiroz
Universidade Federal do Ceará, Fortaleza, Brazil

The outer chorionic sculpturing of phlebotomine sand flies has long been noted to have interspecific variations. In the present work, chorionic sculpturing of eggs of 6 sand fly species of Brazil was examined, for the first time, with the scanning electron microscope (SEM). Three patterns could be identified. Parallel ridges were observed in only *L. whitmani*, subgenus *Nyssomyia*. Polygonal chorionic patterning was detected in *L. migonei*, *L. carmelinoi*, *L. lenti* and *L. evandroi*, all belonging to the species group *migonei*, and *L. fischeri*, belonging to the subgenus *Pintomyia*. The mountain-like pattern was observed in the chorion of eggs of *L. wellcomei*, subgenus *Psychodopygus*. Although all these species but *L. carmelinoi* and *L. lenti* can be easily differentiated by the chorionic sculpturing, it is clear that there is no unique association of a particular pattern with a taxonomic group. Further investigations are in progress on whether or not different chorionic sculpturings reflect different microclimatic conditions present in the oviposition sites.

Financial support from WHO/TDR (M8/181/4/Q.21) and NIH (AI 16305-17).

03-073

MORPHOLOGY, FINE STRUCTURE AND FUNCTION OF PROSOMAL GLANDS IN *TYPHLODROMUS* spp. (ACARI: MESOSTIGMATA: PHYTOSEIIDAE).

G. Nuzzaci, A. Di Palma, P. Aldini, E. de Lillo
Istituto di Entomologia Agraria, Università degli studi di Bari, Italy

On the glands of the prosomatic region in Mesostigmata there are few reports particularly in Phytoseiidae: there is infact very little information both by an anatomical point of view (Starovir, 1973; de Lillo & Aldini, 1994) and their feeding behaviour (Flechtmann & McMurtry, 1992).

A morphological and ultrastructural study on the prosomal glands in females of *Typhlodromus exilaratus* Ragusa and *T. rhenanoides* Athias-Henriot (Mesostigmata: Phytoseiidae) has been made by means of light, scanning and trasmission electron microscopy. All of the studied glands are composed of more than one cell, sometimes with a different cytological structure.

A functional interpretation of them has been proposed on the basis of their anatomy.

Our observations have revealed:

- a salivary gland complex, dorsally located in the propodosoma and connected with the salivary styli;
- coxal glands, observed latero-ventrally located at the level of the first and second pair of legs, which discharge their secretion near the coxal base of the first legs;
- a pair of glands found under the cheliceral base, above the pharynx and in front of the brain; their function is not well understood.

03-072

PROPOSED TECHNIQUES FOR DETECTION OF CHEMOSENSILLA ON THE ANTENNAE OF ADULT DIASPIDIDAE (HOMOPTERA, DIASPIDOIDEA)

F. Porcelli*, L. De Marzo**, A. Frigeri***

* Istituto di Entomologia Agraria - Università di Bari - Italy.

** Dipartimento di Biologia, Difesa e Biotecnologie agro-forestali
Università della Basilicata - Potenza - Italy.

*** Istituto di Fisiologia Generale - Università di Bari

Transmission electron microscopy does not allow the study of a large number of species, mainly because of the need of live insects to process and the long time required for the preparation that must be obtained in a specialized laboratory.

The detection of chemosensilla on the antennae of adult diaspidid can also be obtained with the techniques proposed here:

- i) Confocal Laser Scanning Microscopy (CLSM) allows to observe, on balsam preserved specimens, the dendritic branch channels of the shaft of chemosensilla. CLSM offers the optical sectioning thus it shows the presence of chambers into the shaft; furthermore, CLSM improves both resolution and deep of field if compared with the traditional light-microscopy.
- ii) ii) Fluorescent microscopy can be used to label specifically the cells structures. Several fluorophores appears to be useful to observe sensillary sinus of chemosensilla.
- iii) Crystal violet staining allows researcher to detect chemosensilla; moreover, it is possible to distinguish porous from aporous regions of the shaft. This method was originally proposed by Slifer; it has been modified by Porcelli using the Karnovsky's fixative and the wetting agent TWEEN 80 and was adapted to be used during collection trips.

03-074

MORPHOLOGY AND ULTRASTRUCTURE OF ALIMENTARY CANAL IN *BACTROCERA DORSALIS* (HENDEL)

Wen-yung Lee

Institute of Zoology, Academia Sinica, Taipei, Taiwan, Republic of China

The alimentary canal of *Bactrocera dorsalis* was studied by means of the light microscopiy and the electron miicroscopy. This alimentary canal is a long slander tract composed of the foregut, midgut and hindgut. The foregut is very small and short found in the cervical region and the anterior part of the prothorax, consisting of the oesophagus, crop, and cardia. The oesophagus appears as a tiny tube from the mouth to a bun-like shape of the cardia which is lying in the mesothorax. The crop is a pedunculate sac with a long stalk connecting to the oesophagus a short distance before the cardia. By the long stalk, the crop lies in the anterior part of the abdomen. The midgut is the longest part of the alimentary canal from the cardia to the evagination part of the malpighial tubules. The anterior part lying in the mesothorax is rather small and straight while the posterior coil portion is in the first four abdominal segment. The hindgut consists of the colon and rectum. The former is a coil tube and the latter is large formed as a cucumber shape in the female and s-shaped in males. Both of them have four rectal papillae.

The ultrastructure of the foregut and hindgut possesses a well structure of cuticular intima. The epithelium is moderately developed in the hindgut but barely evident in the foregut. They are surrounded by a single layer of the circular muscles. There is no differentiated proventriculus in *B.dorsalis*. The oesophagus extends into the inner portion of the cardia and the epithelium of the midgut starts from the outer layer of the cardia. There are three types of cells can be found in the midgut: the columnar cells, goblet cells and regenerative cells. The structures and the functions of the cells as well as the rectal papillae are invastigated and described in detailed.

03-075

MORPHOLOGICAL PECULIARITIES OF THE CHORIONIC STRUCTURE OF SOME BEETLE EGGS (COLEOPTERA, TENEBRIONIDAE, CETONIINAE)

M. Carl

Institut für Umweltforschung, Türkenfeld, Germany

For the first time the chorionic structure and the different chorionic layers of the following beetles are described. The critical-point dried eggshell was broken to reveal the different chorionic layers. Surface and cross-section of the chorionic layers are examined by scanning electron microscopy (SEM).

Tenebrionidae:

- *Morica favi* LUCAS: The eggshell consists of two layers. The surface of the outer layer shows a rough and irregular relief as well as its cross-section. The inner layer is characterized by a smooth surface and an even cross-section.
- *Scaurus tristis* OLIVIER: The eggshell consists of two layers. The thin outer layer covers numerous crystals which are embedded into the outer surface of the inner layer. The inner layer shows a rough and irregular relief as well as its cross-section.
- *Pinelia crenata* F.: The eggshell consists of two layers. The outer layer is characterized by numerous pits which partly reach through this layer to the outer surface of the inner layer. The cross-section is rough and irregular. The inner layer is characterized by a smooth surface and an even cross-section.
- *Blaps alternans* BRULLÉ: The eggshell consists of two layers. The surface of the outer layer consists of white wax-like crystals. The inner layer is characterized by a smooth surface and an even cross-section.

Cetoniinae:

- *Eudicella woermanni* KRAATZ: The eggshell consists of at least ten layers. The outer layer shows wide cracks between the wax-like material. The second layer consists of pillar-like material with a roughly broken cross-section. The third layer is characterized by a smooth surface and an even cross-section. The next approximately six layers are similar to fabric with numerous fibres. The last (inner) layer seems to be solid with a rough and irregular relief.

The known chorion of many species of the Cerambycidae, Chrysomelidae, Passalidae, Staphylinidae et cetera in most cases possess micropyles visible on the exterior and interior surface of chorion as well as channels in cross-section. It is remarkable that the eggs of the above mentioned Tenebrionidae and Cetoniinae lack any micropyles and channels extending completely through chorion.

03-076

CORRESPONDING GENITAL MUSCLES IN MALE AND FEMALE MELOLONTHA MELOLONTHA (COLEOPTERA: SCARABAEIDAE) AS INDICATORS OF MORPHOLOGICAL CORRESPONDENCE IN MALE AND FEMALE GENITAL SCLERITES

F.-T. Krell

Theodor-Boveri-Institut für Biowissenschaften, Zoologie III, Würzburg, Germany

The sclerites of ectodermal genitalia are extremely different between both sexes in insects. In the cockchafer *Melolontha melolontha* (L.) males possess a spiculum ventrale and an aedeagus consisting of a phallobasis and two paramera surrounding the endophallus. In contrast, females possess only two pairs of reduced palpi vaginales and two setose fields. Despite these profound differences the genital musculature shows an extensive correspondence in the two sexes which has never been described in Pterygota. By myological comparison of both sexes considering origins, insertions, and topographic correlations of muscles the following hypotheses are inferred (KRELL 1996): 1. Aedeagus and vaginal palps are derivatives of different urites. 2. Spiculum gastrale and vaginal palps are derivatives of urite IX and are therefore morphologically corresponding structures. 3. The caudal part of Spiculum gastrale is of sternal or pleural origin. 4. The aedeagus is derived from urite X (or from intersegmental area IX/X). 5. The bursa copulatrix is derived from urite X (or from intersegmental area IX/X); bursa and aedeagus correspond morphologically. 6. The female genital tract has no sclerites corresponding to the aedeagus.

03-078

ENDOSYMBIONT INCLUSION IN THE OOCYTES OF SILVERLEAF WHITEFLY, *BEMISIA ARGENTIFOLII* (HOMOPTERA: ALEYRODIDAE)

H. S. Costa¹, N. C. Toscano¹, T. J. Henneberry²

¹ Department of Entomology, University of California, Riverside, CA USA; ² USDA-ARS, Western Cotton Research Laboratory, Phoenix, AZ USA.

This study investigates the process of inclusion of endosymbiotic organisms from adult silverleaf whitefly females, *Bemisia argentifolii* Bellows and Perring, into the developing ova. In dissected females, individual mycetocyte cells containing microorganisms were scattered singly among developing oocytes. Oocytes with mycetocytes included were first observed in females 16 h after emergence. The mean number of oocytes ≥ 0.1 mm in length per female increased through the fourth day after adult eclosion then leveled off.

The number of oocytes containing mycetocytes followed a similar pattern. Stages of mycetocyte inclusion followed a pattern based on size of the oocyte. Oocytes became associated with a single mycetocyte cell when they were a mean of length of 0.135 ± 0.003 mm (minimum of 0.11 mm). Mycetocytes were observed inside a common membrane with oocytes, at what becomes the pedicel end of the ova, when oocytes were an average of 0.147 ± 0.004 mm long. In the final stages of ovum development, the plasma of the oocyte completely surrounded the mycetocyte and the chorion was thickened.

Mycetocytes included in oocytes had a mean length of 33 ± 0.4 μ and width of 27 ± 0.5 μ . Although the females that were dissected had opportunity to oviposit, some retained several fully developed ova. Because inclusion of mycetocytes into oocytes is a continuous process, manipulations of endosymbionts before inclusion into the oocytes should be possible at any time during adult life; however, earlier treatment of an individual would likely affect a greater proportion of their offspring.

EYE DESIGN IN THE ELEPHANT HAWKMOTH, *Deilephila elpenor*

P.A. Brännström and Y. Arroyo-Yanguas

Department of Zoology, Lund University, Lund, Sweden

The Elephant hawkmoth, like other moths, have an enormous field of view monitoring almost all directions except for those hidden by the body. We measured the total field of view and the visual overlap between the two eyes. We found that the overlap is largest (30° to 45°) in the antero-ventral region below the animals horizon, while above the horizon it is 30° or less. The area of largest visual overlap is where the animals see the flowers they feed on during their foraging flight.

Using optical and histological methods we obtained values for the sensitivity to white light, S_w , (Warrant & Nilsson 1995) and the interommatidial angle $\Delta \Phi$ (Snyder 1979) across the entire hawkmoth eye. We found the antero-ventral area of maximum binocular overlap to coincide with the region of highest sensitivity and, surprisingly, also the poorest resolution. At the conference, we will provide a possible explanation to this enigmatic eye-design.

Orthographic projections with the sensitivity and interommatidial angle (a measure of image grain-size) in the right eye represented by isolines. The striped border marks the part of eye where the centre of the pseudopupil or eye-glow reach the border of the eye: the maximum field of view is larger. Anterior is to the right in both figures.

03-079

MORPHOLOGY AND DEVELOPMENT OF OVARIES IN ENSIGN SCALE INSECTS (INSECTA, COCCOMORPHA: ORTHEZIIDAE)
T. Szklarzewicz
Department of Systematic Zoology, Institute of Zoology, Jagiellonian University, Kraków, Poland

The paired ovaries of scale insects are telotrophic. Each ovariole is composed of tropharium and vitellarium that contains one developing oocyte. All germ cells of the ovariole originate as a result of synchronous divisions of one stem cell. The tropharia of so far investigated scale insects consist of small number of nurse cells: in Diaspididae and Coccidae - 3, in Pseudococcidae - 7. In these groups stem cells divide two or three times. In ortheziids the number of germ cells in trophic chambers is much higher (about 50 cells). Moreover, tropharium besides nurse cells contains also arrested oocytes. Both the oocyte in the vitellarium and the arrested oocytes are connected with the trophic core via nutritive cords. In the third larval instar the ovaries of *Orthezia urticae* are spindle shaped. They consist of numerous ovariole anlagen. Each anlage is composed of one germ cell cluster and has a form of a rosette. In the centre of each rosette a polyfusome occurs. During the third larval instar cystocytes differentiate into oocytes and trophocytes. Presented observations indicate that ortheziid ovarioles show some peculiar character i.e. the high number of germ cells per cluster, the occurrence of arrested oocytes and the existence of polyfusomes. Anagenesis of hemipteran ovaries is discussed in relation to the presented results.

03-081

FUNCTIONAL ANATOMY OF SALIVARY GLANDS OF *KEROPLATUS REAUMURII* *PENTOPHTHALMUS* GIGLIO-TOS LARVAE (DIPTERA: KEROPLATIDAE).

A. Lucchi, I. Barsotti, L. Santini
Dipartimento di Coltivazione e Difesa delle Specie Legnose, Sezione Entomologia agraria, Università degli Studi di Pisa, Italy.

As occur in most of the Diptera Keroplatidae, larvae of *Keroplatus reaumurii pentophthalmus* emit from the mouth a huge quantity of a mucoid, silk-like substance used, during the whole post-embrional development, for several purposes such as locomotion, protection from biotic and abiotic factors, supply of food and building of the pupal cocoon. Source of this substance are two hypertrophic tube-like salivary glands that open ventrally to the hypofarynx and extend into the abdomen, on either side of the alimentary canal. Gross-anatomy and ultrastructure of these glands were examined during the last larval stage of development. They are entirely formed by unducted unicellular secretory units that discharge the secretion into the gland lumen, which is lined with an intima surrounded by microvilli. Each cell shows a large spheroidal nucleus centrally located and characterized by polythene chromosomes. In the cytoplasm are visible typical secretory organelles such as abundant rough endoplasmic reticulum, very numerous mitochondria most varied in size and shape, free ribosomes and Golgi areas presenting a peculiar rounded vesicular appearance. Numerous secretory vesicles are uniformly distributed throughout the cytoplasm.

03-080

FINE-STRUCTURE OF THE METASTERNAL RESERVOIR OF *NEZARA VIRIDULA* L. (HETEROPTERA: PENTATOMIDAE).

Andrea Lucchi
Dipartimento di Coltivazione e Difesa delle Specie Legnose, Sezione Entomologia agraria, Università degli Studi di Pisa, Italy.

The metasternal reservoir of *Nezara viridula* is a sack-like organ ventrally located below the digestive tract and extending, with the posterior part, into the first two segments of the abdomen. It is devoted, together with the lateral glands, to the production and storage of the defensive secretion of the bug. TEM observations reveal the presence in the reservoir of two different types of secretory units: almost the whole of the surface consists, in fact, of a single layer of unicellular secretory units (type-1 SU), whereas a multilayered structure of columnar cells, constituting a peculiar strip-like organ, is limited to the ventral part of the reservoir (type-2 SU). Type-1 SU are formed by an uninterrupted layer of epithelial cells underlying the cuticular intima and separated from the haemolymph by a very thin basal lamina. Type 2 SU consists of cells presenting an intima, reduced to the epicuticular part, that forms numerous subparallel finger-like invaginations plunging in the cavity of the cells. The cytological features of the type-1 and 2 SU are described in this survey by drawings and TEM micrographs. Particular emphasis is given to the defence behaviour of the bug.

03-082

THE GENITAL ORGANS OF *FRANKLINIELLA OCCIDENTALIS* (PERGANDE) (THYSANOPTERA: THRIPIDAE)

R. Dallai, P. Lupetti, G. Del Bene¹
Dipartimento di Biologia Evolutiva, Università di Siena, Siena, Italia - ¹ Istituto Sperimentale per la Zoologia Agraria, Cascine del Riccio, Firenze, Italia

The female genital organs of the thrips *Frankliniella occidentalis* consists of a pair of ovary and oviducts, a spermatheca and a single accessory gland. The spermatheca is a small-brownish orange organ adhering to the vagina, while the accessory gland is a large structure with an apical bulb and a long duct. Both organs have secretory and duct-forming cells in their epithelium. The short spermathecal duct flows into the vagina through a diverticulum of the vaginal epithelium. This also provides anchorage to muscle fibers which control the opening of duct lumen. The male genital organs consist of two testes, two deferent ducts, two seminal vesicles and two accessory glands. Seminal vesicles and glands open into a large ejaculatory bulb. The accessory glands have secretory epithelium without duct forming cells. Testes and deferent ducts are surrounded by a peritoneal sheath formed by inner muscle fibers and outer pigmented cells. The pigmented cells are not present in the accessory glands. The ejaculatory bulb continues with an ejaculatory duct, the epithelium of which is lined by a thin cuticular intima. At this level the peritoneal sheath becomes thin and has muscle fibers with intermingled pigmented cells, with the latter adhering to the epithelium.

03-083

ULTRASTRUCTURE AND DISTRIBUTION OF A FLAT-TIPPED SENSILLUM IN BAETIDAE (EPHEMEROPTERA)

E. Gaino, M. Rebora¹Istituto di Zoologia, Università di Perugia, Italy - ¹ Istituto di Zoologia, Università di Genova, Italy

The presence of a peculiar flat-tipped sensillum in Baetidae has been demonstrated on the antennal segments of the nymphs of *Baetis rhodani*. This sensillum bears an apical pore and its slightly enlarged tip forms a flange. It is evenly distributed over the surface of the scape and pedicel, whereas forms bridges between consecutive articles of the flagellum. On the basis of morphology and location, we hypothesize that this flat-tipped sensillum functions both as mechano- and chemoreceptor.

A comparative ultrastructural investigation carried out on Italian species pertaining to the genera *Acentrella*, *Baetis*, *Centroptilum*, *Cloeon* and *Procloeon* has revealed that this flat-tipped sensillum is not a common feature of Baetidae. Indeed, it is limited to *Acentrella sinaica* and to some other species of *Baetis* other than *B. rhodani*, namely *B. alpinus*, *B. melanonyx* and *B. buceratus*. It is not found in *B. digitatus* and *B. muticus* or in the representatives of the remaining genera of Baetidae.

This kind of sensillum seems to be a specialization of the basiconic type and constitutes a microcharacter useful for both taxonomy and phylogenetic considerations.

03-085

A SCANNING ELECTRON STUDY OF THE EXTERNAL MORPHOLOGY OF PHLEBOTOMINE SAND FLY LARVAE OF THE GENUS *LUTZOMYIA* (DIPTERA: PSYCHODIDAE) OF A CUTANEOUS LEISHMANIASIS FOCUS IN CEARÁ STATE, BRAZIL.F. A. C. Pessoa¹, R. G. de Queiroz¹, R. D. Ward²¹ Universidade Federal do Ceará, Brazil; ² Keele University, U.K.

Cutaneous leishmaniasis is a disease caused by protozoans of the genus *Leishmania*, which are transmitted to man by phlebotomine sand flies. Although the biology and morphology of adult sand flies have been extensively studied, the immature stages of these insects are not well known. As a result, sand fly species have been routinely identified by only adult characters. The present work describes, for the first time, the ultrastructure of the 4th instar of larvae of 7 species, namely *L. longipalpis*, *L. whitmani*, *L. intermedia*, *L. migonei*, *L. lenti*, *L. evandroi*, and *L. sericea*, and the taxonomic importance of external structures is assessed. Laboratory-reared larvae, first killed in hot water, were fixed in 3% glutaraldehyde, then washed thoroughly in several changes of phosphate-buffered saline, submitted in 1% osmium tetroxide for an hour and dehydrated through a series of alcoholic solutions, critical point dried, and gold sputtered. The specimens were examined with a Hitachi scanning electron microscope S 4500. Interspecific variations were observed in the arrangement of setae of the segments, and morphology of antennae, spiracles, caudal setae and mouthparts. Therefore, these characters may be used as an alternative means of identification of these species.

03-084

OVARIOLE ULTRASTRUCTURE IN *SILO MEDITERRANEUS SATURNIAE* MORETTI (TRICHOPTERA: GOERIDAE)M.C. Bicchieri¹, E. Gaino

Istituto di Zoologia, Facoltà di Scienze MM.FF.NN., Università degli Studi di Perugia, Perugia, Italy

The organization of the meroistic polytrophic ovarioles of *Silo mediterraneus saturniae* Moretti was examined by light microscopy and both scanning (SEM) and transmission (TEM) electron microscopy.

Each ovariole is composed of a linear sequence of follicles the maturation of which is detectable by both dimension values and a superficial polygonal pattern. Structural details of egg cells, follicle cells and nurse cells were observed in follicles in previtellogenic and vitellogenic stages. The loose, net-like texture of the stalk cells is particularly evident between adjacent, fully developed follicles.

The onset of the vitelline envelope is marked by precursor material synthesized by the follicle cells in the form of electron-dense granules. The granules are extruded in the space between the membrane infoldings occurring close to the egg border. The aligned granules fuse together to form linear arrays which give the vitelline envelope an initial striated aspect. By contrast, during choriogenesis precursors are accumulated along the basal region of the follicle cells in a discontinuous layer which gradually becomes an electron-dense, thin and homogeneous sheath.

As choriogenesis proceeds, follicle cells tend to detach from the egg surface giving rise to a scallop-like layer. This arrangement is consistent with the irregularly folded appearance of the chorion in newly ovulated eggs. Under SEM, the egg inclusions are visible underneath the chorion owing to the thinness of this envelope.

The simple organization of the chorion seems to be related to the egg deposition in water-absorbing spumaline which has a protective function.

03-086

A NEW MORPHOLOGICAL STRUCTURE IN *KERMES BOTTARD* (HOMOPTERA COCCOIDEA KERMESIDAE)

S. Marotta, A. Tranfaglia

Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy

Kermes vermilio (Planchon) is a common scale insect living on *Quercus* spp. in the Southern Italy urban environment.

Morphological studies on female and male young instars have showed the presence of ventral frontal lobes. They are situated just antero-medially to each basal antennal segment and have membranous appearance.

Until now, similar lobes were known only in many species of the family Eriococcidae. These structures are here recorded in Kermesidae for the first time and probably they are present in other species of the family.

Their function is unknown.

03-087

CYTO- AND HISTOCHEMICAL STUDIES OF THE OVARY IN *PANORPA COMMUNIS* (MECOPTERA).

B. Simiczyjew

Department of General Zoology, Wrocław University, Poland

The polytrophic ovarioles of *Panorpa communis* are differentiated into a terminal filament, germarium and vitellarium. The germarium contains germ cells clusters (cystoblasts and cystocytes) at early stages of their differentiation. All cystocytes enter the prophase of meiosis, so their ultimate fate can not be predicted at this stage. At the base of germarium the cystocytes become morphologically diversified. One of the central cells of the cluster become the oocyte while the remaining cystocytes transdifferentiate into nurse cells. The oocyte nucleus is spherical and transparent while the nurse cells nuclei become polyploid, they grow rapidly and are filled with numerous DNA- positive granules. The presence of intercellular bridges was revealed by rhodamine - phalloidin staining of F-actin. The intercellular bridges between the oocyte and the nurse cells were found to contain more F-actin than those connecting the nurse cells. The derivatives of one cystoblast - three nurse cells and oocyte are enveloped by follicular epithelium, thus forming an egg chamber. The follicular epithelium is morphologically diversified into a group of densely packed follicle cells around the oocyte, a highly flattened group of cells which encompass the nurse cells and a group of cells which migrate in between the oocyte and nurse cells at the beginning of vitellogenesis. This diversification is also reflected in the organization of microfilaments.

03-089

MORPHOLOGICAL ASPECTS OF ENDOCYTOBIOSIS IN COCKROACHES

L. Sacchi, A. Grigolo, S. Corona, U. Laudani¹, C. Bandi², M.G. Selmi³, E. Bigliardi³

Dip. di Biologia Animale, Università di Pavia, Italy - 1 Ist. di Entomologia, Università di Pavia, Italy - 2 Ist. di Patologia Generale Veterinaria, Università di Milano, Italy - 3 Dip. di Biologia Evolutiva, Università di Siena, Italy

Intracellular symbiotic bacteria have been observed in all cockroaches (Blattaria) examined. They inhabit specialised cells of the fat body, are transovarially inherited, and appear to be essential for the growth and reproduction of their hosts. Molecular phylogenetic analyses placed the symbiotic bacteria of the Blattaria among the favobacteria and indicated that the infection occurred in an ancestor common to cockroaches and termites. The endocytobionts are enveloped by a vacuolar membrane derived from the host cell (the bacteriocyte). Ultrastructural studies of the host and symbiont membrane systems were performed in three Blattaria families (Blattellidae, Blaberidae, Cryptocercidae). The results show the presence of vesicles originated from blebbing processes of the vacuolar membrane and of close adhesion sites between this membrane and the prokaryote cell envelope. Freeze-fracture replicas evidence aggregates of intramembrane particles on the vacuolar membrane. A blebbing of the symbiont outer membrane is described in the Cryptocercidae. The vesicles detaching from the symbiont outer membrane could be a mechanism for releasing symbiont products in the vacuolar space. The transovarially transmitted symbiotic population is integrated in the ontogenetic processes. In *Periplaneta americana* (Blattellidae), after the acquisition of the bacteria, the formation of a "mycetome" is observed. The mycetome is made up of a syncytial envelope, probably formed by the vitellophages, that contains a considerable symbiont ball. During the embryonic development, there is a progressive decline in the bacterial population, caused by lytic processes which take place inside the mycetome. In the following phases of embryogenesis, a residual bacterial population abandons the yolk sac and moves to the epineural sinus, where it is phagocytized by the embryonic plasmatocytes which then become bacteriocytes. The formation of these cells follows a pattern similar to that observed in *B. germanica* (Blattellidae). Therefore, the bacteriocyte formation took place, within the order Blattaria, following similar coadaptive processes.

03-088

INTERNAL REPRODUCTIVE ORGANS IN ADULT MALE *POLISTES DOMINULUS* (CHRIST) (HYMENOPTERA: VESPIDAE)

G. Salerno and S. Turillazzi

Centro di Faunistica ed Ecologia Tropicali, CNR, Florence, Italy

In the genus *Polistes*, as in most Hymenoptera, spermatogenesis ceases in the late pupal stage (Machida, 1934; Pardi, 1947). Apart from that, very little is known about the male internal reproductive organs. This study provides a morphological and histological description of the internal reproductive organs of male *Polistes dominulus*.

Adult males, emerged from colonies reared in the laboratory, were divided according to age, fixed in Pamp's fluid and dissected in alcohol. The reproductive tracts of some individuals were drawn under a camera-lucida and used for measurement, while others were embedded in polystyrene, sliced into 8 µm sections and stained for light microscopy.

The internal reproductive organs of male *P. dominulus* consist of a pair of testes joined medially, paired seminal vesicles, accessory glands and ducts. At emergence, the testes are loaded with sperm, the seminal vesicles show a corrugated internal surface with very few sperm, the accessory glands have a thick wall with active columnar cells and scanty secretory product in their lumina. After emergence the testes slowly degenerate and the sperm descend into the seminal vesicles. The thickness of the gland wall decreases and a lot of secretory product is found in the gland lumen. With increasing age, the testes size decreases and the gland size increases.

Males older than 2-3 days store many sperm in their seminal vesicles and are therefore capable of mating repeatedly.

The increase in size and content of the accessory glands suggests that their secretion not only contributes to the seminal liquid, but could also be functionally involved in the territorial mating system of this species. In this reproductive strategy males are active in territories for more than one month (Beani and Turillazzi, 1988).

03-090

SPIRACULAR MORPHOLOGY OF IMMATURE STAGES OF PHLEBOTOMINE SANDFLY (DIPTERA, PSYCHODIDAE).

A.M. Fausto*, M. Maroli**, M. Mazzini* and M.D. Feliciangeli***.

* Department of Environmental Sciences, University of Tuscia, Viterbo, Italy. **Department of Parasitology, Istituto Superiore di Sanità, 00161 Rome, Italy. ***School of Medicine, Faculty of Health Science, University of Carabobo, Nucleo Aragua, Maracay, Venezuela.

Insect larval spiracular system assumes a great variety of forms. Many of the changes observed in different systems are clearly adaptative. In the present investigation, the morphology of the spiracles of fourth instar larvae of eight sandfly species (*Phlebotomus perniciosus* Newstead, *P. papatasi* Scopoli, *P. perfiliewi* Parrot, *Lutzomyia longipalpis* (Lutz & Neiva), *L. ovallesi* Ortiz, *L. youngi* Feliciangeli & Murillo, *L. evansi* Nuñez-Tovar, *L. trinidadensis* Newstead were examined by scanning electron microscopy.

Larvae of phlebotomines are amphipneustic, having 2 pairs of spiracles: the metathoracic one is situated at the anterior edge of the second thoracic segment; the post abdominal pair is on the posterior corner of the eighth abdominal segment. In the larvae of the all eight species both the anterior and posterior spiracles are placed at the top of a globular body. Their structure includes an external opening with a closing apparatus and a peritreme which surrounds it. The latter has rose-like shape, consisting of a circularly arranged petal-like protuberances, separated each from the other by elongated septa. Each petal is longitudinally crossed by an elevated linea divide the petal in two identical parts.

The taxonomic and phylogenetic value the specific features of spiracular morphology is discussed.

03-091

MORPHOLOGY AND ULTRASTRUCTURE OF THE CEPHALIC VESICLES OF THE DRYININAE AND GONATOPODINAE LARVAE (HYMENOPTERA, DRYINIDAE).

M. Carcupino¹, A. Guglielmino², M. Mazzini¹, M. Olmi²¹ Department of Environmental Sciences, University of Tuscia, Viterbo, Italy - ² Department of Plant Protection, University of Tuscia, Viterbo, Italy

Dryinidae are parasitoids of Homoptera Auchenorrhyncha. The larvae are usually partly ectoparasitic. The posterior part of the parasitoid body protrudes from the host between two overlapping sclerites, whereas the anterior part draws in the haemocoel of the host. The head of larvae of Dryininae and Gonatopodinae shows two vesicles in front of their face. These structures are usually considered to be involved in the feeding of the first larval instars. In order to obtain new data useful in clarifying the real function of these structures, the external morphology and the internal organization of the cephalic vesicles have been examined in the following species: *Dryinus collaris* (L.) (Dryininae); *Gonatopus communis* Olmi, *G. atlanticus* Olmi and *G. camelinus* Kieffer (Gonatopodinae).

03-092

SULFATION AS A POSSIBLE MECHANISM TO REGULATE VITELLOGENIN TRANSIT THROUGH EPITHELIAL CELLS IN *CARAUSIUS MOROSUS* OVARIAN FOLLICLESA. Cecchetti¹, A. Falleni, M.T. Locci, F. Giorgi
Department of Biomedicine, University of Pisa

During vitellogenesis the fat body synthesizes a number of non-vitellogenic proteins that are transferred to the ovarian follicles along with vitellogenins (Vgs). While Vgs are stored in the oocyte to sustain embryonic development, non-vitellogenic proteins are thought to play a major role to regulate endocytic uptake and/or trigger onset of early development. A non-vitellogenic protein has recently been identified in the stick insect *Carausius morosus* (Giorgi et al., 1995). This is a fat body derived protein of 157 Kd that is selectively sulfated during vitellogenesis. Data proved that it is neither labelled with ³H-acetylglucosamine nor with ³⁵S-SO₄²⁻ in cultured fat body. This suggests that sulfoconjugation takes place upon transfer to the ovarian follicle rather than upon secretion from the fat body and that it is not associated with the carbohydrate moiety of the protein. In order to verify this possibility a number of developmentally different ovarian follicles were exposed both *in vivo* and *in vitro* to ³H-acetylglucosamine or ³⁵S-SO₄²⁻ for time exposures ranging from 30 minutes to 8 hours. Samples were then processed for fluorography, scintillation counting and high resolution autoradiography. Autoradiographs were quantitatively analyzed according to the procedure set up by Salpeter (1978). When observed at the EM level, follicle cells appear characterized by an extensive endocytic activity along the apical end and by numerous secretory vesicles throughout the cortical cytoplasm. Autoradiographic analysis of ovarian follicles exposed to ³⁵S-SO₄²⁻ demonstrate that radioactivity is first associated with the Golgi apparatus of the follicle cells, followed by secretion into the interfollicular spaces and finally it is localized over the microvillar area between the follicle cells and the oocyte. With longer time exposures to the radioisotope, some of the radioactivity appears associated with the cortical ooplasm. Data are interpreted as suggesting that the 157 Kd protein is sulfated within the follicular epithelium, following a transcytotic pathway through the follicle cells. By doing so this sulfated protein may contribute to forming the extracellular matrix of the interfollicular cell channels. In addition, it may also provide some binding sites for the incoming Vg so as to retain it in the interfollicular channels prior to interaction with the oolemma.

03-093

HEMOPOIESIS IN THE STICK INSECT *CARAUSIUS MOROSUS*M.T. Locci, A. Cecchetti¹, M. Masetti¹, F. Giorgi
Department of Biomedicine, ¹Department of Environmental Sciences, University of Pisa, Italy

The problem concerning the origin of hemocytes in insects is far from being elucidated. While hemocytes in the adult are known to be produced by specialized hemocytopoietic organs of mesodermal origin (Ratcliffe et al., 1985), those in the embryo are thought to originate from median mesodermal cells (Romoser and Stoffolano, 1994). In many insect species, these organs have been identified and histologically characterized (Gupta, 1985). The hemocytes of the stick insect *Carausius morosus*, i.e. plasmatocytes, granulocytes and spherulocytes have already been identified in the adult (Locci et al., 1995). Cells with similar ultrastructural characteristics were also identified amongst those released by *in vitro* cultured embryonic yolk sac. In the present study, the heterogeneous cell population released by the yolk sac has been characterized both morphologically and immunohistochemically. Hemocytes in *C. morosus* were shown to react against ConA and an anti-vitellogenin monoclonal antibody (Mab B12), besides responding to a phenoloxidase test. These same reactivities were thus used to verify whether some of the cells released by the yolk sac were embryogenetically related to hemocytes. Some of these cells reacted with all three substrates, suggesting that they could potentially behave as hemocytes. Based on these observations we propose that the yolk sac may provide stem cells capable of differentiating into hemocytes upon migrating to an embryonic hemocytopoietic organ, the embryonic dorsal vessel. Several lines of evidence suggest the dorsal vessel of the adult insect as a potential hemocytopoietic organ. Dorsal vessels from a number of stick insects were thus cultured for over 15 days in Grace's medium supplemented with adult hemolymph. During this culture period different kind of cells were released into the culture medium. Ultrastructural analysis of these cells demonstrated that they are morphologically similar to different classes of hemocytes, i.e. plasmatocytes, granulocytes and spherulocytes. On the basis of these observations we postulate that the dorsal vessel in stick insects behaves as a hemocytopoietic tissue both in the embryo and in the adult. The cells that are released by the yolk sac upon *in vitro* culturing are interpreted as stem cells, partly differentiating as hemocytes and partly contributing to the embryonic dorsal vessel.

03-094

HAMANN'S ORGANS AND THEIR SIGNIFICANCE FOR STAPHYLINOIDEA BEETLES OF AGYRTID — COLONID GROUP OF FAMILIES (AGYRTIDAE, LEIODIDAE, COLONIDAE) PHYLOGENY UNDERSTANDING

E. E. Perkovsky

International Solomon University, Department of Biology, Kiev, Ukraine

Hamann's organs are to be found on the 7th, 9th and 10th antenna segments of leiodid beetles and consist of periarticular gutters on the distal surface of 7th, 9th and 10th antennal segments and usually vestibulums and vesiculums, which often occupy the main part of the volume of the 7th and part of the 9th and 10th segments (Accordi, Sbordoni, 1978).

The 7th antenna segment of the Cretaceous form *Nyujwa* Perkovsky (Leiodidae, Camiarinae, Neopeltopini) from Baikal region is extended enormously, the 8th is strongly reduced, the 9th is slightly narrower than 7th, 10th is strongly narrower than 9th, 11th is strongly narrower than 10th.

The reduction degree of *Nyujwa* the 8th segment is common to recent Leiodidae with typical for the family interrupted 5-segmented club. A strong extension of the 7th, 9th and 10th antennal segments in recent Leiodidae is always connected with Hamann's organs development on these segments.

Easier access to the 7th segment Hamann's organs of Cretaceous Leiodidae was to be reached through the 8th segment reduction. At the same time periarticular gutter does not appear on the 7th segment distal surface of the colonid antenna, and their 8th segment is never reduced, which is proof to attribute Colonidae to the related Agyrtidae, but different from Leiodidae phyletic line.

Accordi, F., Sbordoni V., 1978. The fine structure of Hamann's organs in *Leptodirus hohenwarti*, a highly specialized cave Bathysciinae (Coleoptera Catopidae). Int. J. Speleol. 9 : 153-165.

DESCRIPTION OF IMMATURE STAGES AND LIFE HISTORY OF OXYNA PARIETINA L. /DIPTERA: TEPHRITIDAE/ ON ARTEMISIA VULGARIS /ASTERACEAE/ IN CZECH REPUBLIC

J. Kinkorová, M. Jokeš
Department of Entomology, Research Institute of Plant Production, Prague, Czech Republic
Oxyna parietina L. is univoltine and nearly monophagous on native mugwort *Artemisia vulgaris* /Asteraceae/ in Czech Republic.
Larvae develop singly in and feed in stems of the host plant.
The egg is described and illustrated in detail in plant tissues for the first time.
The third instar larvae and puparium are described and figured using scanning electron microscopy.
Life history of *Oxyna parietina* is described and potential use as a biocontrol agent for *Artemisia vulgaris* in Czech Republic is discussed.

03-097

LTSEM MORPHOLOGICAL STUDIES ON *DICYPHUS* (D.) *ERRANS* (WOLFF) (HETEROPTERA: MIRIDAE).
A. Minnocci, R. Petacchi
Scuola Superiore di Studi Universitari e di Perfezionamento "S. Anna", Pisa, Italy
Dicyphus errans is a Mirid predator of glasshouse and field crop phytophages (mites, aphids, whiteflies) of cultivated Solanaceae and Cucurbitaceae.
Morphological observations of frozen-hydrated specimens of adults and preimaginal stages were conducted by Low Temperature SEM.
Egg characteristically show two short respiratory horns on the apex, arising from the anterior margin of the body of the shell, laterally from the elliptic operculum. The eggs are deeply embedded in plant tissue while the operculum-horn complex emerges from the leaf surface. Subsequently during embryonal development the operculum moves away from the respiratory horns, which remain attached to the chorion.
The first three antenna articles bear sensillar fields of 10-30 "smooth peg" sensilla on the dorsal surface. No differences exist between male and female adults while in the preimaginal stages sensilla reside only in first two segments. In the dorsal first article of adults and preimaginal stages there is a placoid sensilla. Numerous sensilla tricoidea and chaetia are present in all the articles. First and second instars show very numerous small smooth sensilla on the second and third articles between scattered long grooved sensilla chaetia.
Examination of the mouthpart morphology show that the rostrum has numerous "hair-like" mechanoreceptor sensilla all along its surface. The bipartite apex (separated by the dorsal stilet groove) reveals one terminal field of 9-11 peg sensilla on each lateral lobe.
Between the meso- and metathoracic adult legs, on the lower border of the episternum, there is the pterotoracic scent gland orifice. It has a peritreme surface constituted by specialized mycoid microsculpture involved in the of discharged secretion dispersion mechanism. In nymphs, on the other hand, the scent gland system is dorsal and abdominal.

03-096

ANTENNAL CHEMOSENSILLA IN *CARAUSIUS MOROSUS* BRÜNNER (PHASMIDAE)
R. Petacchi, A. Minnocci
Scuola Superiore di Studi Universitari e di Perfezionamento - "S. Anna" Pisa, Italy
To date few morphological and ultrastructural observations concerning the antennal chemosensilla in stick insects (*Phasmidae*) are available. The objective of the current study is to provide further information on these sense organs in *Carausius morosus*.
Throughout the parthenogenetic female antenna there is a low number of sensilla in the first half and a markedly increasing density in the second half. Mechanosensitive sensilla of different types (peg-like, bristle-like and campaniform), a small number of poreless thermo-hygrosensitive (Altner et al., 1978) and chemosensilla have been found.
Three types of chemosensilla have been identified. Type 1 has a cuticular apparatus (outstanding hair-shaft) 100-150 µm long, gradually tapering from the base (5-6 µm in diameter) to the tip, with fluted aporous walls and spatulate tip. The cross sections of hair show a double lumen formed by the cuticle. Inside the innervated lumen there are arc unbranched dendrites of five receptor cells. They have different diameters and the pattern of their microtubules is 5x2+1 or 7x2+3. The section in the ciliary sinus shows the thick dendritic sheath that wraps the five outer dendritic segments and the tubular body. This structure is typical of sensilla with gustative function.
Type 2 is a "hair-like" sensilla. It is shorter than type 1 (80-90 µm) and has a smaller diameter (4-5 µm at the base); it has a blunt tipped and smooth walls. Ultrastructural investigation demonstrated the presence of pores and spoke channels that perforate the thick cuticular wall of the hair. This type seems to be an olfactory sensilla. The number of sensory cells is from four to six.
"Peg-like" sensilla (type 3) are less abundant and smaller (15-25 µm in length and 2-3 µm in diameter at the base), peg-shaped and blunt tipped. The hair, in cross section, shows a relatively thin cuticular wall and displays a high density of pores each leading into numerous pore tubules. The latter are surrounded by a wider liquor channel filled with receptorlymph, similar to the hair lumen. The cellular components consist of a greater and variable (5 - 22) number of sensory neurons. The dendritic segments are first enclosed in a common sheath and later divide into numerous branches.
Altner H., Tichy H., Altner I. (1978) - Cell Tiss. Res., 191: 287-304.

03-098

MORPHOLOGY OF THE STOMODEUM IN LARVAE OF SOME TRICHOPTERAN FAMILIES
G. Spinelli Batta, C. Corallini Sorcetti
Istituto di Zoologia, Università di Perugia, Perugia, Italy
The larvae of some families belonging to the Trichoptera Order, have some cuticular structures such as spines, teeth and bristles in the stomodeum and particularly in the proventriculus.
In this study, the Authors examined, under scanning electron microscope, mature larvae from the following families and genera: Rhyacophilidae (*Rhyacophila*), Hydropsychidae (*Hydropsyche*, *Cheumatopsyche*), Polycentropodidae (*Polycentropus*, *Plectrocnemia*), Phryganeidae (*Agrypnia*), Odontoceridae (*Odontocerus*) which have a largely carnivorous feeding regime.
In *Hydropsyche* and *Cheumatopsyche*, these structures are very complicated and consist of elaborate tooth-like, spiniform processes called "gastric mills" by Boon (1983-85).
In *Rhyacophila* the spines are distributed along longitudinal ridges.
In *Polycentropus* and *Plectrocnemia* both spines and fringes of long bristles are present.
In *Agrypnia* the spines are numerous and uniformly distributed all over the proventriculus; in the crop there are a few small spine-like tubercles, and at pharyngeal level there are spines again.
Odontocerus has small combs with teeth of different sizes, distributed longitudinally at the beginning of the proventriculus and variously disposed in its caudal portion.
In conclusion, morphological examination of the stomodeum reveals differences between the various families but the complexity of the proventriculus does not seem to be related to the feeding regime. *Rhyacophila*, exclusively predatory and carnivorous, has only some series of spines whereas *Hydropsyche*, which is filter-feeder and has an omnivorous feeding regime, has "gastric mills".

03-99

HEMOLYMPH PUMPING MECHANISM IN THE
LOCUST MIDLEG

R. Hustert, B. Reichert, M. Hardt

Zoologisches Institut, Universität Göttingen, Berliner Str. 28, D-37073
Göttingen, Germany

An oblique diaphragm separates the trochanter and the femur in locust midlegs and blocks the passage of hemolymph in the leg's ventral compartment. The only distal outlet is into the ventral blood vessel of the femur. It is supplied with a flap-like valve that opens when the diaphragm is pulled proximally by two muscle bundles. This is a rhythmic movement that is usually synchronized with increased hemolymph pressure arising from the expiratory phase of ventilation. When the muscle bundles relax during inspiration the diaphragm flattens due to the antagonistic tension produced by its elastic tissue and by cross striated muscle fibres which are arranged radially on the diaphragm.

The muscle bundles that pull at the diaphragm are supplied by a single excitatory motoneuron. A different single neuron extends over the diaphragm and may have modulatory function on its muscle fibres and possibly on other parts of the leg, for immuno-histochemistry has shown a high content of serotonin in it.

03-101

THE CYTOSKELETON IN OVARIAN CLUSTERS OF
POLYTROPHIC MEROISTIC INSECTS

R. Rübsam and J. Büning

Zoological Institute I, University of Erlangen, Erlangen;
Germany

We comparatively investigate the cytoskeleton of polytrophic meroistic ovaries in several insect orders (adephage coleopterans, neuropterans, hymenopterans, trichopterans, lepidopterans, mecopterans and dipterans). Well known are the dynamics of the *Drosophila* egg chamber cytoskeleton (e.g. Cooley and Theurkauf (1994), *Science* 260: 590-596). To what extent are these results also valid in other insect orders?

Our data clearly demonstrate that the occurrence of actin filaments in prominent cytoskeletal structures, like the fusome or the ovarian ring canal is no common feature typical of all orders, but differs depending on the group. For example there is no actin detectable in the *Drosophila* fusome, while in hymenopterans and especially in adephage coleopterans it seems to be an abundant component of this organelle. The association of actin with ring canals does not show a unique pattern as well, but varies in several ways throughout the groups studied so far. While the protein is largely absent to ring canals in adephage coleopterans, lepidopterans, trichopterans and mecopterans, its association with hymenopteran ring canals is restricted to a short period of cluster development.

Inquiry of additional cytoskeletal molecules during insect oogenesis is in progress.

Supported by DFG grant to J.B.

03-100

ULTRASTRUCTURAL AND IMMUNOCYTOCHEMICAL STUDY OF
KARYOSPHERE AND NUCLEAR BODIES IN INSECTS WITH
DIFFERENT TYPES OF OVARIOLES.D.S. Bogolyubov, O.A. Alexandrova, A.G. Tsvetkov, E.M. Antipanova,
M.N. Gruzova.Laboratory of Cell Morphology, Institute of Cytology, St. Petersburg,
Russia

The morphological features of diplotene oocyte nuclei were studied for some insects with different types of ovarioles: *Tenebrio molitor*, *Tentyria nomas taurica* (Coleoptera), *Chrysopa perla* (Neuroptera) and *Galleria melonella* (Lepidoptera). The ultrastructural analysis of karyosphere in different insects showed several patterns of its formation. In all species studied except *T. molitor* the karyosphere has a fibrous capsule. Apart from the karyosphere, the numerous extrachromosomal nuclear bodies (NB) of different morphological types appear in oocytes of all species studied. They seem to be involved in karyosphere capsule formation. In *T. molitor* where the capsule is absent, some NB are present in the karyosphere. According to immunocytochemical data and in situ hybridization of U2 snRNA some NB contain snRNP and non-snRNP splicing factor SC 35 and can be referred as analogues of B snurposomes of amphibian oocyte nuclei. Other NB contain the coilin-related protein and snRNP and they are similar to coiled bodies of somatic cell nuclei. In all cases the karyosphere contains snRNP. Staining of tenebrionid oocyte nuclei with antibodies against fibrillarin and in situ hybridization to rDNA gave negative results, which allows conclusion to be made that nucleoli are absent in oocytes of tenebrionids and that is why the karyosphere does not contain fibrillarin. By contrast, in *C. perla* and *G. melonella* oocyte nuclei the nucleoli exist. The karyosphere capsule in *C. perla* oocytes contains fibrillarin. It can be connected with the nucleoli involvement in capsule formation.

03-102

SPHERES (BINNEKÖRPER) FROM CRICKET AND DAMSELFLY
OOCYTES CONTAIN FACTORS OF SPLICING pre-mRNA AND
PROCESSING OF pre-rRNAA.G. Tsvetkov, M.N. Gruzova¹, J. Gall²Laboratory of Cell Morphology, Institute of Cytology RAS, St. Petersburg,
Russia-1, and Carnegie Institution, Baltimore, USA-2

By the method of immunocytochemistry it has been shown that spheres from cricket and damselfly oocyte nuclei contain small nuclear RNA (snRNA) and fibrillarin - protein involved in pre-rRNA processing. Besides in cricket oocyte spheres coilin-related protein has been revealed. It is known that coilin is a part of intranuclear structure called coiled body in somatic cells. By the method of hybridization nucleic acids in situ U1, U2 and U6 snRNAs has been identified in spheres of cricket oocytes. Concentration of U2 snRNA was much higher compared to U1 and U6 snRNA. After longtime (24h) incubation of cricket's ovary in medium containing ³H-uridine spheres remained unlabelled by contrast with heavily labelled karyoplasm.

The data obtained show homology between spheres from studied insects and coiled bodies of somatic cell nuclei, spheres from amphibian oocyte nuclei and prenucleolar bodies in nuclei formed in vitro in *Xenopus laevis* egg extract after adding DNA.

03-103

NOTE ON THE FEMALE REPRODUCTIVE SYSTEM OF SOME PUPIPARA (DIPTERA, NYCTERIBIIDAE, HIPPOBOSCIDAE)

G.V. Faraŋonova

Department of Biology, Moscow State University, Moscow, Russia

The position of Nycteribiidae in the system of Diptera is still questionable. Deep changes of their external and internal morphology caused by parasitism make it difficult to determine the relationships of these flies. Nycteribiidae possess adenotrophic viviparity, and their larvae develop in the female organism feeding on the secretion of accessory glands. These glands are great in size, tubular and very branched organs connected by the ducts with uterus-like dispair oviduct. The comparative anatomic analysis of the glands showed many similar features in their morphology in Nycteribiidae and Hippoboscidae. Symbiotic bacteria are found in all examined species. Though the secretion in both families takes place on merocrine pattern, some differences are discovered in the ultrastructure of secretory cells. Hippoboscidae have an extra-cellular reservoir at each secretory cell. The reservoir is separated from the gland duct by cuticular net. Nycteribiid cells have not such structure, and the secretion take place directly in the gland ducts. Apparently, these physiological and morphological distinctions prove phylogenetic separation of Nycteribiidae and Hippoboscidae.

03-105

OBSERVATIONS ON MORPHOLOGY AND BIOLOGY OF *CALAMONCOSIS APRICA* MG. (DIPTERA, CHLOROPIDAE)

M. Grochowska

Department of Zoology, University Mariae Curie-Skłodowska, Lublin, Poland

All the development stages of *C. aprica* were being observed from May to August in the years 1973-1974; 1985-1986. The material was collected by means of the observation, analysis of reed stems, laboratory breeding and the scop method. Morphology of the egg, the first, second, third stages of the larva and of pupa was described and illustrated. Female and male terminalia, not known so far, were described. On the bases of a few years' observations it has been established that *C. aprica* appears in great numbers in galls of *Platycephala planifrons* (F.) on Common reed (*Phragmites australis* Trin.) stems. In a particular stem there were from 8 to 58 larvae. Eggs, the first and second larval stage were found in the first half of June. The third stage was observed from the middle of June till the middle of July. Pupa appeared in the second half of June and was presente there till the middle of July. Adult were collected over the reed from the third decade of June to the third decade of August. It is supposed that *C. aprica* has two generations within one year. It is known that the Summer generation develops on the reed in galls of *Platycephala planifrons* and its larvae are phytophages. Winter generations probably appear in galls of *Lipara*, and their larvae feed rotten plant substance.

03-104

A SCANNING ELECTRON MICROSCOPICAL STUDY OF LARVAL STRUCTURES IN AFRICAN DIPTERA.

E. De Coninck

Entomology Section, Royal Africa Museum, Tervuren, Belgium.

The head structure, spines and papillae of the segments, and the anterior and posterior spiracles of larval stages were studied by Scanning Electron Microscopy.

The main morphological features are illustrated by micrographs.

03-106

ULTRASTRUCTURE OF THE ENDOCRINE CELLS IN THE MIDGUT EPITHELIUM OF THE COCKROACH, *PERIPLANETA JAPONICA*

C. H. Yu and W. - K. Kim¹

Department of Biology, Inha University, Inchon, S. Korea
- ¹ Department of biology, Korea University, Seoul, S. Korea

The endocrine cells in the midgut epithelium of the cockroach, *Periplaneta japonica* were observed by the light and electron microscope. The midgut epithelium of the last instar larva and adult cockroach was consisted of principal columnar cells, regenerative cells, and endocrine cells. Midgut endocrine cells were positioned basally in the epithelium as cone-shaped single cell or underneath the regenerative crypt cells. When midgut epithelium grows and the cell composing it transform, between the endocrine and regenerative cells were made desmosome type junction and large vesicular shaped stretches of loose contact. The endocrine cells were characterized by a clear cytoplasm with abundant Golgi complex and numerous secretory granules. The secretory granules in the cell were spherical, unit membrane bound, and osmiophilic electron dense granules about 200~400nm diameter. The secretory granules have been observed as discharged by exocytosis on the basal, lateral side of the cell.

03-107

THE FINE STRUCTURAL ASPECTS OF COCOON SILK PRODUCTION IN THE SPIDER, *ARGIOPE AURANTIA*
M.J. Moon, M.A. Townley¹, E.K. Tillinghast¹

Department of Biology, Dankook University, Cheonan 330-714, KOREA - ¹ Department of Zoology, University of New Hampshire, Durham, NH 03824, U.S.A.

The silk glands of araneid spiders are of several types. Among these, the principal fibers used in constructing the eggcase are products of the cylindrical glands (or tubuliform glands) which are present only in females. And development of these glands parallels maturation of the ovaries.

The cylindrical gland spigots of the garden spider, *Argiope aurantia*, have a noticeably wider aperture than those serving other types of silk glands, reflecting the relatively large size of the cylindrical gland fiber. Examinations of formed fibers indicate a multicomponent internal structure, and highly magnified electron micrographs reveal each fiber contains numerous electron lucent fibrils embedded in an amorphous electron dense matrix.

These heterogeneous fibers not necessarily taking place in a uniform manner throughout the length of the cylindrical gland. By the several evidences obtained from light and electron microscopical observations, a mechanism related to eggcase silk formation can be presented.

03-109

THE EGG SHELL FORMATION AND CHORION FINE STRUCTURE OF *HYDROMETRA STAGNORUM* (HETEROPTERA)
B.Simiczjew, A.Ogorzałek

Department of General Zoology, Wrocław University, Poland

The hydrometrid egg shell layers are secreted by follicular epithelium, after the vitellogenesis has been completed. The vitelline membrane is the first to be formed, and its formation is preceded by an increased of rough endoplasmic reticulum and increase in the number of dictyosomes, then by accumulation of secretory vacuoles which are secreted from the cell to the space between the oocyte and follicular cells. There the material accumulates, fuses and forms consecutive layers on the surface of oocyte. The vitelline membrane is formed around the entire oocyte and shows no local modifications. The chorion is two-layered: compact endochorion and complex exochorion composed of air chambers. The egg capsule comprises three specialized regions of different structure: micropylar apparatus, the main part of the egg covered with ridges and the posterior pole with attachment disc. The distinct regions of the egg capsule are produced by different groups of follicular cells.

03-108

WOUND HEALING PROCESS OF THE INTEGUMENT IN THE SPIDER, *PARDOSA ASTRIGERA* (ARANEAE: LYCOSIDAE)

Moon-Jin Jeong, Myung-Jin Moon

Department of Biology, Dankook University, Cheonan 330-714, KOREA

The integument of cephalothorax in the wolf spider, *Pardosa astrigera*, was consist of outer cuticle and a epidermal cell layer. After puncturing of the integument by sharp needle, the wounds were gradually healed along with the following two processes: (1) Coagulation and wound plug formation by hemocytic migration, (2) Regeneration of the epidermal cell layer and secretion of a new cuticle.

Shedding of the hemolymph was immediately blocked by the coagulation, and formation of the wound plug was initiated by the accumulation of hemocytes at the wounding site. This step was accomplished within 12 hours after wounding, and it was found that the granulocyte was the most predominant type among the several types of hemocytes.

Reconstruction of the epidermal cell layer beneath the wound plug was first detected at 10 day sample, and production of new cuticle through the apical surface of the epidermal cells appeared at 14 days after wounding.

03-110

THE FUNCTION, MECHANICS AND DESIGN OF HINDWING FANS.

Robin Wootton

Department of Biological Sciences, University of Exeter, Exeter EX4 4PS, UK

The hindwings of most flying Orthoptera, Phasmida and Dictyoptera appear to gain most aerodynamic force from the downstroke. This comes partly from the initial 'peel', but also from the main translational phase, as the wing sweeps downward and forward. The fan appears subtly designed to maximise lift by a semi-automatic mechanism, the 'umbrella effect', which creates camber and depresses the trailing edge by compressing and slightly buckling the radiating veins. This is made possible by the fan shape, which approximates to part of a logarithmic spiral, and can be modelled as such both physically and mathematically to predict a theoretical optimal design. The great variability which actually occurs seems less determined by fine aerodynamic and energetic considerations than by the need to maintain an adequate area of total lifting surface in insects whose forewings are adapted to variously degrees for protection, rather than flight.

The fans of locusts, which are spectacular long-distance fliers, show many refinements on the basic form. These appear to enhance the umbrella effect, while minimising the energy expended in creating it.

03-111

Ultrastructure of digitiform sensilla on the hypopharynx of larval *Elodes marginata* FABR. 1798 and *Flavohelodes flavicollis* KIESW. 1859 (Coleoptera: Scirtidae).

U. HANNAPPEL & H.F. PAULUS

Institut of Zoology University of Vienna, Austria

Sensilla are called digitiform if their hairshaft lies in a longitudinal and superficial groove built by the cuticle. Digitiform sensilla are widespread in different orders of insects like Coleoptera, Lepidoptera and Diptera. These sensilla are found on the antenna and the maxillar- and labialpalpi in larvae and imagines. However in larval *Elodes* and *Flavohelodes* digitiform sensilla are only found on the hypopharynx. Therefore it is important to know if such sensilla have always the same ultrastructure and function.

The four digitiform sensilla on the keel-sclerite of the hypopharynx of larval *Elodes marginata* and *Flavohelodes flavicollis* were investigated by electron microscopy.

In the two species the digitiform sensilla don't show any structural divergences of their ultrastructure. Each sensillum consists of a poreless, massive hairshaft, which lies in the superficial, cuticular groove. The basis of this peg is surrounded by typical joint-structures. At its tip the outer dendritic segment contains the tubular body and terminates on the basis of the hairshaft. A single bipolar sensory cell innervates each sensillum.

The tubular body demonstrates that digitiform sensilla on the hypopharynx in larval *Flavohelodes flavicollis* and *Elodes marginata* are mechanosensitive sensilla.

Following conclusion can be made:

In literature the term "digitiform sensilla" bases only on the external cuticular morphology of these sensilla. However our results proof that this term unites a multitude of sensilla of different types and functions.

03-113

THE ANTENNAL CIRCULATORY ORGANS OF HYMENOPTERA: FUNCTIONAL MORPHOLOGY AND PHYLOGENETIC IMPLICATIONS

S. MATUS, G. PASS

Institute of Zoology , University of Vienna, Austria

The antennal circulatory organs of 38 species of Hymenoptera were investigated by light and electron microscopy. In *Apis* this organ consists of an unpaired ampulla from which blood vessels originate extending into the antennae. The ampulla is a very delicate structure of elastic connective tissue. It connects to the head hemocoel via numerous small wall perforations. No specific ampulla muscles exist, but contraction of the pharynx dilators causes ampulla compression, thereby forcing hemolymph flow into the antennae.

The functional type of antennal circulatory organ without directly-acting ampulla muscles is common to all other Hymenoptera. In some anatomical characters, however, these organs vary considerably between taxa. There are also species with two ampullae; some have a hemolymph channel connecting the ampulla with the dorsal vessel; others have a pumping case for the ampulla formed by cuticular apophyses. There are also differences in number and morphology of the ampulla openings. The distribution of all these characters and the implications for phylogenetic systematics of Hymenoptera are discussed.

03-112

THE MORPHOLOGY OF THE CIRCULATORY ORGANS IN DIPLURA: THE ANCESTRAL CHARACTER STATE IN INSECTS?

B.-A. GEREKEN, G. PASS

Institute of Zoology, University of Vienna, Austria

In contrast to pterygote insects, the circulatory organs of Diplura show a number of characters which demand special interest.

Diplura are unique in comparison to all other insects in their antennal vessels being connected to the anterior end of the dorsal vessel. Most insects possess pulsatile organs at the base of the antennal vessels which work independently of the dorsal vessel. In all subtaxa of the myriapods, there is a connection of the antennal vessels to the dorsal heart comparable to that of Diplura. This is considered the plesiomorphic state of the Tracheata. The connection of those vessels was apparently lost during the evolution of the Ectognatha.

Another remarkable feature of the circulatory system in the head capsule is a vessel ring which encompasses the gut and connects the dorsal vessel to a short ventral vessel. This feature is shared by Diplura, Archaeognatha and Zygentoma but not by any pterygote insect. A similar construction was found in Chilopoda and the possible homology of these structure is discussed.

Modifications in the morphology of the posterior end of the dorsal vessel and in the auxiliary guiding structures which take part in the hemolymph supply of the different abdominal appendages were found in Diplura, Archaeognatha, Zygentoma and Ephemeroptera. This contribution sets out to scrutinize the evolutionary pathways and transformations of these circulatory organs.

03-114

WING CIRCULATORY ORGANS AND POSTEMBRYONIC DEVELOPMENT OF THE DORSAL VESSEL IN THE THORAX OF NEUROPTERIDA (INSECTA).

T. GATSCHNEGG, H. W. KRENN, G. PASS

Institute of Zoology, University of Vienna, Austria

The auxiliary pumps of insect wings consist of a cuticular part forming the pump casing and of a pulsatile pumping structure. The present investigation compares the wing circulatory organs and the course of the dorsal vessel in the thorax on the basis of semithin serial sections in 32 species of Megaloptera, Raphidioptera and Neuroptera.

All Megaloptera have a pulsatile diaphragm in each pterothoracic segment which is distant from the dorsal vessel. The latter bears no ostia. In the Raphidioptera, the wing circulatory organ in the metathorax is different from that in the mesothorax. In the metathorax, the dorsal vessel has an ampullary enlargement with a pair of ostia close to the pulsatile diaphragm. In the mesothorax, the dorsal vessel is distant from the pulsatile diaphragm and has no ostia. In most investigated Neuroptera, the pulsatile diaphragms in both winged segments are directly attached to the dorsal vessel, which has a pair of ostia. In a few species, however, the pulsatile diaphragm is separate from the dorsal vessel.

Studies of the postembryonic development reveal that larval instars and imagines are comparable with regard to the course of the dorsal vessel and the occurrence of ostia.

The phylogenetic pathways of the wing circulatory organs exhibit several convergent transformations toward the appearance of separate pulsatile diaphragms. Spatial and developmental constraints are discussed as possible reasons for the evolutionary diversification of wing circulatory organs.

03-115

THE SEGMENTAL BLOOD VESSELS OF *PERIPLANETA AMERICANA*B. Mayer¹, G. PassDepartment of Evolutionary Biology, Institute of Zoology,
University of Vienna, Austria

Segmental blood vessels are lateral arteries of the dorsal heart tube which occur in the Blattodea and in some Mantodea. *Periplaneta americana* has a pair of short vessels in the meso- and metathorax and longer paired vessels in the 3rd to the 6th abdominal segments. The functional morphology of the heart and the segmental vessels is analyzed by light and electron microscopy. The segmental blood vessels lie entirely in the pericardial sinus and have no direct connection to the perivisceral sinus. They originate from the ventrolateral walls of the dorsal vessel and extend laterally, finally ending near the pleurae in the fat body. At first glance the segmental vessels appear as simple hemolymph spaces in the fat body, but they have a very delicate wall of connective tissue. While the dorsal vessel wall is muscular, no muscle fibers could be detected in the segmental vessels. At their origin there is a clump of loosely-packed, irregular cells which clearly have the function of a valve. *In vivo* observations of the activity of the dorsal vessel and the hemolymph flow through the segmental vessels indicate that the valves open independently of each other and show no correlation to the contractions of the dorsal vessel. The results are interpreted with regard to both functional and phylogenetic aspects.

03-117

THE ULTRASTRUCTURE OF THE GUT AND THE PERITROPHIC MEMBRANE IN FEMALES OF THE TICK *IXODES RICINUS*

P.A. Diehl, L. Gern, M. Vlimant

Institut de Zoologie, Université, Emile-Argand 11,
2007 Neuchâtel, Switzerland

Many blood sucking arthropods possess a peritrophic membrane. Generally, ticks do not produce a peritrophic membrane except in the argasid tick *Ornithodoros moubata* (Grandjean, 1984) and several *Ixodes* species: *Ixodes ricinus* (Samson, 1909, Zhu et al., 1991, Zhu et al., 1993), *I. scapularis* (Rudzińska et al., 1982), *I. persulcatus*, *I. hexagonus*, *I. trianguliceps*, and *I. uriae* (preliminary results: Gern et al., 1995). The peritrophic membrane is thought to constitute a mechanical barrier for the penetration of pathogens such as the spirochete *Borrelia burgdorferi* (Hayes and Burgdorfer, 1992).

Using SEM and TEM electron microscopy, we reexamined in detail the structure of the gut and the peritrophic membrane in females of *I. ricinus* during feeding and the subsequent pre- and oviposition period. Special attention was paid to the foregut-midgut junction, the hindgut, and to the deposition and subsequent fate of the peritrophic membrane. The first signs of synthesis and deposition of the membrane appear earlier than the 18 hours after beginning of feeding previously reported by Zhu et al. (1991). The formation of the membrane is closely associated with the microvilli.

We hope that our studies will lead to a better understanding of the role(s) of the peritrophic membrane for the behaviour of pathogens in this tick.

03-116

HISTOCHEMICAL STUDY OF QUEENS SPERMATHECA OF *Atta sexdens rubropilosa* ANTS (HYMENOPTERA:FORMICIDAE)

M.I. Camargo-Mathias.

Departamento de Biologia, UNESP, Rio Claro, SP, CP 0199, CEP
13.506-900, Brasil.

The spermatheca is a structure found in insects whose function is to store sperm from the time of copulation to time of egg fertilization. It consists of a pouch internally lined with a cuticle and frequently presenting associated spermathecal glands responsible for the production of spermathecal fluid.

The objective of the present study was to perform a morpho-histochemical study of the spermatheca of queens of *Atta sexdens rubropilosa* ants involving tests for the detection of lipids, proteins and polysaccharides. The material was fixed in 4% paraformaldehyde and embedded in JB4 resin (Polaron Instruments Bio Rad) for histological processing.

The spermatheca of the queen has the morphology of a bilobate pouch whose lobes fuse in the middle portion of the structure. No secretory gland was detected in association with the spermatheca, but groups of cells with secretory characteristics (one group in each lobe) forming a sort of acinus were observed. The histochemical tests applied revealed that the spermathecal secretion at the intracellular level is basically of a protein and polysaccharide nature in these insects. This secretion, however, may be modified in the pathway from the secretory cell to the spermathecal lumen. The storage portion of the spermatheca has thin walls consisting of epithelial cells and lined internally with a cuticle. This epithelium reacted positively to most of the histochemical tests applied. Some investigators suggest that the reduced thickness of the reservoir wall may permit the passage of products other than those secreted by the glandular cells of the spermatheca.

DEPENDENCE BETWEEN HEART BEAT, GAS EXCHANGE RHYTHMS AND BODY MOVEMENTS IN *GALLERIA MELLONELLA* PUPAU. Tartes, A. Kuusik¹, A. Vanatoa²

Institute of Zoology and Botany, Tartu, Estonia - 1 Institute of Plant Protection, Estonian Agricultural University, Tartu, Estonia - 2 Institute of Zoology and Hydrobiology, Tartu University, Tartu, Estonia.

During pupal development in *Galleria mellonella* pupae there exist clear periods of rhythmic abdominal movements described as bending movements in *Tenebrio molitor* pupa (Tartes & Kuusik, 1994, *Physiol. Entomol.*, **19**, 216-222). These abdominal movements are independent from gas exchange cycles. Besides, in *Galleria mellonella* there exist irregular abdominal rotations and often gas exchange is abolished by abdominal rotation movements.

In young and middle-age pupae the heart activity periods alternate with the heartbeat pauses. In late pupae the heartbeating is almost incessant and sometimes is interrupted by short (5-6 s) pauses while common pattern is the alternation of the periods of slow and fast heartbeats and also small and large systole amplitudes.

In most middle-age and in few young pupae more than 80% of heart activity periods typically coincide with the bouts of abdominal pulses. In older pupae often heartbeat and body movements are strictly synchronized.

It could be suggested, that phenomenon, where contractions of abdominal muscles support the heartbeat, is widespread among insects. The supposed function of rhythmic body movements to support circulation may be an example of economic exploitation of the same movement for different tasks in insect.

03-119

MORPHOLOGICAL TYPES AND PHYSIOLOGICAL RESPONSES OF ANTENNAL OLFACTORY RECEPTOR NEURONS IN THE DESERT LOCUST, *SCHISTOCERCA GREGARIA* (ORTHOPTERA: ACRIDIDAE)

S. A. Ochieng¹, E. Hallberg¹, B.S. Hansson²

¹Department of Structural Zoology, University of Lund, Sweden

²Department of Animal Ecology, University of Lund, Sweden

Morphological features of antennal sensilla of the desert locust, *Schistocerca gregaria*, were investigated with scanning and transmission electron micrographic techniques. Three types of olfactory sensilla were identified: sensilla coeloconica, sensilla basiconica and sensilla trichodea. S. coeloconica were situated in cuticular pits in the antennal surface. They contained one-to-four sensory neurons and double walls penetrated by slit-like pores. S. coeloconica showed high excitatory responses in a dose-dependent manner to some plant odours and organic acids that have recently been identified from odours emitted by locust nymphs. Conversely, this sensillum type was inhibited by most semiochemicals produced by the locusts and shown to affect the gregarization behaviour. S. basiconica contained up to 50 sensory neurons and each neuron displayed massive dendritic branching towards the distal end. The sensillum wall was penetrated by a high number of pores. In contrast, s. trichodea contained one-to-three sensory neurons that sent unbranched dendrites into the sensillum lumen and the sensillum wall was penetrated by relatively fewer pores. Both s. basiconica and s. trichodea showed excitatory responses to gregarization pheromone compounds and plant odours but were not affected by the organic acids.

03-121

CARDIAC ACTIVITY OF THE ADULT BUDWORM, *HELIOTHIS VIRESCENS*

A.M. Angioy, D. Boassa, D. Dulcis, Helke Hartlieb¹, P. Muronì, I. Tomassini Barbarossa

Dipartimento di Biologia Sperimentale, Sezione di Fisiologia Generale, Università degli Studi di Cagliari, Cagliari, Italia - 1 Max-Planck Institut für Verhaltensphysiologie, Seewiesen, Germany

The present investigation aims at determining the most significant parameters of cardiac activity in the adult budworm, *Heliothis virescens*. Monopolar extracellular recordings of electrophysiological heart activity were obtained by using metal electrodes positioned on the dorsal cuticular body surface of intact, restrained specimens. Signals were led off via a negative-capacity amplifier, displayed on a CRO and stored on a magnetic recorder. As in the case of other insect species (Angioy and Pietra, 1995; Ai and Kuwasawa, 1995), the regular cardiac activity in *Heliothis* consists of the cyclic alternance of a fast phase with a slow phase, which are distinguishable on the basis of their action potential frequencies and durations. The fast phase comprises a high-frequency action potential discharge (135.60 ± 0.03 pulses/min) lasting 36.72 ± 8.65 s. The slow phase consists of a low-frequency action potential discharge (59.40 ± 0.06 pulses/min) lasting 64.44 ± 15.19 s. The interspike interval gradually increases from the beginning to the end of the fast phase, while it decreases in the first two-thirds of the slow phase and thereafter increases in the final third of the phase. The regular action potential frequency of each phase is greatly affected following stimulation of external sensory receptors located on several areas of the insect body. Time-course analysis of consequent electrocardiographic changes indicates that, as in the case of other insect species (Angioy et al., 1987; Ai and Kuwasawa, 1995), sensory-induced cardiac responses occur in the adult budworm, *Heliothis virescens*. Angioy A.M. (1988) J. Insect Physiol. **34**, 21-27; Angioy A.M. and Pietra P. (1995) J. Comp. Physiol. B **165**, 165-170; Ai H. and Kuwasawa K. (1995) J. Insect Physiol. **41**, 1119-1131.

03-120

ACCESSORY PULSATILE ORGANS: MODEL SYSTEMS FOR NEUROBIOLOGICAL AND EVOLUTIONARY STUDIES

G. PASS¹, H.W. KRENN¹, B.-A. GEREKEN¹, W. HERTEL², H. AGRICOLA²,

1) Institute of Zoology, University of Vienna, Austria
2) Institute of Zoology, University of Jena, Germany

Compared to the closed vascular system of vertebrates, the open circulatory system of insects seems simple. The hemolymph is propelled through the body cavity by the tubular dorsal heart. The action of this pump alone, however, cannot effect circulation in long body appendages such as antennae, legs, wings, ovipositors, and cerci. Many insects possess small pulsatile organs for hemolymph exchange in these structures, which in most cases are completely independent from the dorsal vessel.

Comparative studies of the functional morphology of these accessory pulsatile organs in representatives of most insect orders revealed an unexpected diversity of construction. For this reason, these organs are significant for phylogenetic systematics and for general aspects of organ evolution. The reconstruction of their evolutionary pathways elucidates their origin by the recruitment of the individual components from different organ systems and the formation of new functional units. In several cases, their structural transformation and individualization can be explained by modifications of other organ systems.

Due to their capability of autonomous rhythm generation and the fact that they consist of only very few components, the accessory pulsatile organs are also ideal objects for studying the function of simple nerve-muscle systems.

03-122

MORPHOLOGY OF THE TUBULAR HEART OF THE BLOWFLY *PROTOPHORMIA TERRAENOVAE*

I. Tomassini Barbarossa, M. Dardani, P. Muronì, N. Piroddi, A. Antonelli, S. Spiga¹, G.P. Serra¹

Dipartimento di Biologia Sperimentale, Sezione di Fisiologia Generale, Università di Cagliari, Italia - 1 Dipartimento di Biologia Animale ed Ecologia, Università di Cagliari, Cagliari, Italia

Several research studies have been performed on cardiac activity and its sensory-induced changes in blowflies (Thon, 1980; Angioy and Pietra, 1995). However, very few morphological data of the contractile organ have been described in these insect species (Jensen, 1977). We report herein the results of a laser scanning confocal microscopy study on the vessel of the adult fly, *Protophormia terraenovae*. The abdominal portion of the pulsating dorsal vessel, arbitrarily called the heart, is made up of chambers in series. They are provided with lateral valve-like openings, resembling the incurrent ostia already described in other insect species. The heart wall is richly supplied by a widespread network of tracheoles deeply embedded among myocardial cells. The abdominal portion of the vessel continues with a cylindric thoraco-cephalic part, generally called the aorta, six to eight times smaller in diameter than the abdominal heart. Neither ostia nor tracheoles are present in the thoracic aorta, which extends to the head and terminates with an enlarged opening into the brain. The vessel wall consists of a layer of muscle fibers between two sheets of connective tissue. Myocytes show large nuclei, which protrude externally and internally with respect to the vessel wall in the aorta and in the abdominal heart respectively. The outer and inner perimysial layers are quite similar to those described in Orthoptera (Baccetti and Bigliardi, 1969) and contain longitudinal elastic-like and circular periodic banded collagenous-like fibrils respectively. Angioy A.M. and Pietra P. (1995) J.Comp. Physiol. B **165**, 165-170; Baccetti B. and Bigliardi E. (1969) Z. Zellforsch. **99**, 13-24; Jensen H. (1977) Cell Tiss. Res. **180**, 293-302; Thon B. (1982) J. Insect Physiol. **28**, 411-416.

THE EVOLUTIONARY AND ECOLOGICAL SIGNIFICANCE OF METAMORPHOSIS AND ITS HORMONAL REGULATION.

H. F. Nijhout

Department of Zoology, Duke University, Durham, NC USA

Insect evolution is characterized by progressive divergence in the morphology of larval and adult stages. Metamorphosis is the process by which a larval form with one set of adaptations transforms into an adult form with a different set of adaptations. In addition to the sequential changes of metamorphosis, many insects can develop into one of several distinct alternative morphologies at some stage in their life cycle, each with unique specializations. The distinctive forms that develop in these sequential and alternative polyphenisms are genetically identical. They arise through discrete switches in developmental pathways, usually in response to specific stimuli from the environment. The endocrine system provides the transduction mechanism between the environmental signals and the developmental pathways. Juvenile hormones, ecdysteroids, and neurohormones are known to be involved in the regulation of these developmental switches.

Switching of developmental pathways occurs during relatively brief hormone-sensitive periods. Typically one of two alternative pathways is chosen, depending on whether the hormone is above or below a given threshold. When a choice must be made between more than two possible developmental alternatives this is generally managed through a temporal sequence of several binary switching events. This flexible and modular developmental regulatory mechanism has enabled the great evolutionary radiation of insects, and will be discussed in the context of metamorphosis, caste determination in social insects, and horn polymorphism in scarab beetles.

04-002

THE ENDOCRINE REGULATION OF THE PROCESS OF ECDYSIS DURING METAMORPHOSIS

James W. Truman, John Ewer, and Steven Gammie
Department of Zoology, University of Washington,
Seattle WA, USA

In *Manduca sexta* the injection of eclosion hormone (EH) into molting animals triggers the sequential performance of the pre-ecdysis and ecdysis behaviors. Part of this response to EH treatment includes the production of cyclic GMP in a group of 50 neurons that contain crustacean cardioactive peptide (CCAP). For larval ecdysis this increase occurs well into pre-ecdysis behavior, about 10-15 min before ecdysis, and increases the excitability of these cells. The number of cells showing the cGMP increase as well as its timing relative to ecdysis varies according to metamorphic stage.

The role of EH in triggering ecdysis-related events needed to be reexamined in light of the recent discovery of the ecdysis triggering hormone (ETH; Zitnan et al., *Science*, 1996). A careful determination of the timing of EH release revealed that the major release of this peptide occurs well into the pre-ecdysis behavior, at the time when the CCAP cells show their increase in cGMP. This timing also coincides with that of ETH release. Our current data suggest that EH and ETH have a positive feed-back relationship which insures the massive release of both hormones. This "spike" of peptides would provide an unequivocal signal that commits the animal to attempting ecdysis.

04-003

THE ROLE OF NEUROPEPTIDES IN METAMORPHOSIS

Hiroshi Kataoka

Department of Biotechnology, Graduate School of Agriculture and Agricultural Life Sciences, The University of Tokyo, Yayoi, Bunkyo-ku, Tokyo 113, Japan

It is well known that insect molting and metamorphosis are regulated by various neuropeptides. During past 10 years, these neuropeptide, such as prothoracicotropic hormone, eclosion hormone, allatotropin and allatostatin have been purified and chemically characterized. Furthermore, the cDNAs and/or genomic DNAs of these hormones have cloned and sequenced. In this talk, Our research on these neuropeptides is reviewed.

04-004

CASTES AND METAMORPHOSIS

A. Strambi, A.Rachinsky¹, C. Strambi

CNRS, Laboratoire de Neurobiologie, 31 ch. J. Aiguier 13402, Marseille cedex 20, France. -1 Zoologisches Institut, LS Entwicklungsphysiologie, auf der Morgenstelle 28, D-7400 Tübingen, Germany.

In social insects, individuals belonging to a same species and a same sex, display remarkable differences in their morphology (polymorphism) and/or in their behavior (polyethism). The determination of these differences occurs at critical periods during the development under the influence of morphogenetic hormones (i.e. ecdysteroids and juvenile hormone). The presentation will survey the role of juvenile hormone and ecdysteroids on caste specific features of various social insects. We shall focus on reviewing our present knowledge on the timing of hormone action in epigenetic determination of morphology and behavior.

04-006

TRANSCRIPTIONAL ANALYSIS OF JUVENILE HORMONE SENSITIVE GENES DURING INSECT METAMORPHOSIS

Grace Jones

School of Biological Sciences, University of Kentucky, Lexington Kentucky, U.S.A., 40506, GJONES@POP.UKY.EDU

The promoters of juvenile hormone (JH)-sensitive, and one JH-insensitive gene were isolated from *Trichoplusia ni*, and sequences necessary for, or affecting, transcriptional activity were identified by biochemical and functional methods. The transcription start point for each of the genes were determined biochemically, by both primer extension and the sequencing of multiple, independent full-length cDNA clones. The function of each inferred transcription start point as an actual transcription start point was confirmed by in vitro transcription assay. Using the in vitro transcription system, a minimal core promoter of 60 bp (bp -34 to +24) of the *BJHSP1* (basic JH suppressible protein 1) gene, containing a single TATA box motif approximately 30 bp upstream of the transcription start point, was functionally sufficient to support alpha-amanitin-sensitive transcription. The same construct was also transcriptionally functional in a homologous cell line transfection assay. The corresponding region of the other hexamerin genes also contains a similarly positioned TATA box motif, and promoter constructs for each that included the transcription start point, initiator and inferred basal transcription apparatus binding site were all transcriptionally functional in cell line transfection assay. The action of sequences 5' to the minimal promoter region in modulating the rate of transcription was shown by a cell line transfection assay of a nested deletion series of the promoter for the gene encoding BJHSP1, in which the results identified a strongly suppressive element between positions -160 and -109. This system of genes, including those sensitive to JH and one not sensitive, should be useful in a comparative approach toward identifying those regulatory motifs that are functionally necessary to transduce the regulatory action of JH.

04-005

REGULATION OF THE ECDYSONE-INDUCED CASCADE IN *MANDUCA* AT METAMORPHOSIS BY JUVENILE HORMONE

L. M. Riddiford, T. Shinoda, B. Zhou, K. Hiruma, M. Asahina, M. Jindra
Department of Zoology, University of Washington, Seattle, WA, USA

The polymorphic epidermis of the tobacco hornworm makes first several larval cuticles, then at metamorphosis switches and produces a pupal cuticle. When day 2 5th instar larval epidermis was exposed to 500 ng/ml 20-hydroxyecdysone (20E) for 24 h *in vitro*, all cells became pupally committed. The presence of juvenile hormone (JH) prevented this switch. During the exposure to 20E alone, the mRNAs for both isoforms of the ecdysone receptor (EcR) and for E75A showed a biphasic increase, first peaking at 3-6 h, then rising again between 12 and 24 h. The constitutive Ultraspiracle (USP) mRNA showed no change until after 6 h, then increased. Broad-Complex (BR-C) mRNA first appeared at 6 h, then increased steadily. E75B mRNA showed no change. A comparison of the cellular changes during this period with those occurring *in vivo* during pupal commitment in response to 75 ng/ml 20E equivalents showed that the initial responses are those seen during the commitment phase whereas by 18-24 h the cells are beginning to show the predifferentiative changes associated with the prepupal rise of ecdysteroid. In the presence of 1 µg/ml JH I or methoprene, the initial increases in EcR-A and -B1 mRNAs were unchanged, but the second rise was prevented as was the later rise in USP mRNA. Also, the appearance of BR-C mRNA was prevented in these larvally committed cells. By contrast, the initial increase in E75A mRNA was nearly twofold higher, and this increased level was maintained throughout the culture. Initial experiments indicate that the higher level of E75A mRNA is due to an increased transcription rate in the presence of JH and that inhibition of protein synthesis during pretreatment with JH can block this effect. Thus, the role of JH is to modify some early responses to 20E which prevent the later appearance of metamorphic-specific transcription factors such as BR-C.

Mode of action of RH-5992(Ecdysteroid agonist) in pest control operations

A.Retnakaran,S.R.Palli,W.Tomkins,and M.Primavera
Canadian Forest Service, Sault Ste.Marie, Canada

Upon ingestion by lepidopteran larvae, RH-5992 induces an incomplete precocious molt which results in the death of the insect. Similar to the natural hormone, this agonist binds to the ecdysteroid receptor and initiates a cascade of gene expression, if the larva is exposed to this compound early in the stadium before ecdysteroid secretion. If the larva feeds on this material later in the stadium after the ecdysteroid peak, there is no immediate molt induction but the effect is manifested early in the subsequent larval stadium. The spruce budworm, *Choristoneura fumiferana* has six larval instars and all of these stages are sensitive to RH-5992. No phenotypic effects can be seen in the pupal and adult stages. Of all the larval instars, the second instar which is the stage in which this insect overwinters, is the most sensitive stage to RH-5992. The transcription factor, CHR3, is expressed in response to either RH-5992 treatment or at the onset of ecdysteroid secretion and has been routinely used as an assay to detect the initiation of molting. The diapausing second instar does not express CHR3 throughout the stadium but when exposed to even extremely low levels of RH-5992 this gene is expressed. Ecdysteroid receptor is present in low levels throughout development but no ecdysteroid is secreted during the diapausing second instar larva, making this stage very responsive to this agonist.

Since within 12 hr after ingestion of RH-5992 the larva goes into the molting phase, one of the earliest physiological effects is the cessation of feeding. This is very significant in terms of its control potential because it limits the destruction of the host. The lepidopteran specificity combined with feeding inhibition makes this compound an environmentally attractive control agent. Some examples of its proposed use will be illustrated with results from field trials.

PEST CONTROL BY INTERFERING WITH MOLTING AND METAMORPHOSIS

S.R.Palli, T.R.Ladd and A. Retnakaran, Natural Resources Canada, Canadian Forest Service, P.O.Box 490, Sault Ste.Marie, Ontario P6A 5M7 Canada.

The steroid hormone, ecdysone, initiates and coordinates molting and metamorphosis through a cascade of gene expression and repression events. Like other steroid hormones, ecdysone acts through intracellular receptors at the transcriptional level. The stable ecdysteroid analog RH-5992 controls insects by interfering with the process of molting. To understand the mode of action of this compound and to verify whether it is possible to interfere with molting and metamorphosis by either over or under expressing one or more of the key regulatory molecules, we recently cloned three members of the steroid hormone receptor superfamily: *Choristoneura* ecdysone receptor (CfEcR), *Choristoneura* hormone receptor 2 (CHR2) and *Choristoneura* hormone receptor 3 (CHR3) from the spruce budworm, *Choristoneura fumiferana*. The mRNAs for these three receptors increase in abundance during the ecdysteroid peaks for embryonic, larval, pupal and adult molts but not during the intermolt periods. Upon feeding RH-5992 induces the expression of CfEcR, CHR2 and CHR3 mRNA in midgut, fat body and epidermis of *C. fumiferana*. The induction pattern for each of these receptors is similar in both *in vitro* using 20E and *in vivo* using RH-5992. However, the time course of induction for each of these receptors is different. CfEcR was induced within an hour of exposure to 20E or RH-5992, and reached maximum levels by 3 hr following which it decreased to normal levels by 6 hr. CHR2 mRNA was induced within an hour after exposure to 20E or RH-5992, and reached maximum levels by 3 hr followed by a decrease after continuous exposure for 6 hr. CHR3 mRNA started increasing at 3 hr and rose to a maximum level in 6 hr. After continuous exposure to 20E or RH-5992 for 12 hr, the mRNA levels started declining. SEX DETERMINATION IN DIPTERANS AND THE ROLE OF SEX-LETHAL

D. Bopp, M. Meise, D. Hilfiker-Kleiner, A. Dübendorfer and R. Nöthiger.

Institute of Zoology of the University Zürich, CH-8057 Switzerland.

Among dipterans, different strategies are employed to select and stably maintain male or female development. Nevertheless, these strategies may be based on a common principle in which a primary signal controls the activity of a binary switch gene (1). In the best studied system, *Drosophila melanogaster*, the *Sxl* gene assumes this switch function. When ON, it imposes female development; when OFF, male development ensues. Likewise, genetic studies in the housefly, *Musca domestica*, have identified a putative master switch gene *F* which directs female development when ON, and male development when OFF (2).

We have investigated if the *F* and *Sxl* switch functions are founded on common molecular grounds. Analysis of a *Sxl* homologue in the housefly reveals a high degree of structural similarity and, when introduced into *Drosophila*, shows conservation of the molecular functions. However, the *Sxl* gene is not subject to sex-specific regulation in *Musca*. Thus, this gene cannot act as a switch in sex determination of the housefly and does not correspond to *F*. In *D. virilis*, and in contrast to *D. melanogaster*, the *Sxl* homologue expresses large amounts of a male-specific protein variant in the developing CNS of male embryos (3). It is thus conceivable that this gene may also perform functions not related to sex determination. *Sxl* may be an example for the functionally divergent evolution of a regulatory molecule.

SEARCHING FOR SEX DETERMINING GENES IN *CERATITIS CAPITATA*: ANALYSIS OF GENES HOMOLOGOUS TO *DROSOPHILA MELANOGASTER* SEX-LETHAL (*SXL*) AND *DOUBLESEX* (*DSX*).

G. Saccone, I. Peluso and L.C. Polito

Dipartimento di Genetica, Biologia Generale e Molecolare, Università "Federico II" di Napoli, Italy

In *D. melanogaster*, sexual development is controlled by a hierarchical cascade of regulatory genes (*Sxl* > *transformer* > *dsx*) and regulation of these genes involves sex-specific RNA processing. As in no other Diptera (neither Arthropoda) the molecular basis of sex determination has been elucidated yet, we focused our studies on the Mediterranean fruit fly, *C. capitata* (Diptera), also known as an important agricultural pest. We isolated the homologue of *Sxl* in *C. capitata* (*CcSxl*) and found that this gene encodes for highly conserved protein-products (79% of similarity). In contrast to *Drosophila*, however, this gene is not sex-specifically regulated, but produces the same gene-products in males and females. Therefore, we focused our attention on the bifunctional gene *dsx* which in *Drosophila* acts at the bottom of the *Drosophila* sex regulatory cascade. *dsx* in *Drosophila* encodes sex-specific proteins with opposing functions in sexual differentiation. Male and female-specific proteins share a common amino-terminal part which contains a zinc-finger DNA binding domain, but differ in sequence at the carboxy-terminal ends. We isolated sequences from *C. capitata* which are homologous to *dsx* in *D. melanogaster*. Sequence analysis of an ovarian, a female adults cDNAs and a genomic clone show a high percentage of identity at the nucleotide and amino acid level. The cDNA clones contain coding sequences at the 3' end which correspond in composition to those in female-specific *dsx* transcripts in *D. melanogaster*. Also, *Ccdsx* encodes a conserved zinc finger domain in the amino-terminal part of its gene-products. Preliminary RNA analysis of males and females suggests the presence of sex-specific transcripts in *C. capitata* indicating that *Ccdsx* may perform sex-specific functions. Germline transformation experiments are in progress to test whether *Ccdsx* acts as a bifunctional switch gene in sexual development of *Ceratitis*. These data will be discussed in the light of the "bottom-up" hypothesis of how sex determination pathways have evolved (Wilkins, *BioEssays* 17 no. 1, 71-77).

SEX-PEPTIDE REGULATES VITELLOGENIC OOCYTE PROGRESSION VIA JUVENILE HORMONE.

M. Soller, M. Bownes¹, E. Kubli

Institute of Zoology, University of Zürich-Irchel, Winterthurerstrasse 190, CH-8057 Zürich, Switzerland - 1 Department of Molecular Biology, University of Edinburgh, Edinburgh EH9 3JR, UK.

Mating elicits two well defined responses in females of *Drosophila* and other insects: receptivity is reduced and oviposition is increased. Central to the control of receptivity and oviposition in *D. melanogaster* is the sex-peptide (SP), a 36 amino acid peptide synthesized in the accessory glands. During copulation it is transferred into the female. Injected, or ectopically expressed, SP induces reduced receptivity and increased oviposition, the two post-mating reactions observed after mating.

The induced changes imply that the nervous system and (neuro-)endocrine factors are involved in the response of the female to the SP. We have focused on the elucidation of regulatory mechanisms of the SP reaction cascade which lead to the maintenance of the oviposition response. Mated or SP-injected females produce large numbers of eggs which is reflected by an activation of oogenesis. The production of yolk proteins by the fat body and the ovary plays a major part in this process. Quantitative comparison of hemolymph and ovarian yolk protein levels, their rates of synthesis and the levels of yolk protein transcripts in the fat body and ovary shows that the fat body is continuously producing vitellogenin while synthesis and uptake are enhanced in the ovary. This suggests that the regulation is at the level of vitellogenic oocyte progression. Application of the juvenile hormone (JH) analogue methoprene leads to the same changes in vitellogenesis as mating or SP-injection does, indicating that JH acts downstream of SP.

EXTRAORDINARY REPRODUCTIVE AND DEVELOPMENTAL MODES IN HYBRID STICK-INSECTS WITH SUBSTITUTION, ELIMINATION, ADDITION OF WHOLE GENOMES

Y. Scali
Dip. Biologia Evoluzionistica Sperimentale, Univ. Bologna, Italia.

The genus *Bacillus* comprises two well differentiated bisexual species which have repeatedly hybridized to produce two hybridogenetic taxa (*B. rossius-grandii benazzii*, *B. rossius-grandii grandii*) and a corresponding allodiploid parthenogen (*B. whitei* = *B. rossius/grandii grandii*); *B. rossius* has always been the maternal ancestor. Male hybridogens are sterile, whereas females are fertile. Electrophoretic gene-enzyme markers show that hybridogenetic eggs pass the whole maternal haploset (*rossius*) to progeny, whereas the paternal genome (*grandii*) is eliminated; later it is replaced through real fertilization by that of a host fathering male, so that hemiclinal hybrids are restored each generation. Genetic and chromosomal markers also demonstrate that the egg genome can be completely eliminated and an all-paternal, non-hybrid progeny of both sexes are produced through the fusion of two spermheads of the several entering the egg (androgenesis). Depending on the fathering taxon, a single female can originate androgens of different species/races. Furthermore, several hybridogenetic-androgenetic mosaic specimens are obtained; when their differently originated cell-lines are discordant for sex chromosomes, mosaics are also intersexual. Androgenetics can similarly originate from the clonal parthenogen *B. whitei*, following fertilization by *B. grandii* or *B. rossius* males. Fertilized eggs of *B. whitei* are even capable of incorporating a third genome to produce fertile "synthetic" triploids. The genome addition promotes genetic diversification in their progeny owing to a partially restored recombination in the allotriploid eggs. All this gives evidence that no genomic imprinting is at work in stick insects and it also suggests the existence of much more flexible breeding systems than usually assumed for hybrid/unisexual organisms.

04-014

WHY DO NOT DIPLOID MALES OCCUR IN THE FIELD POPULATION OF THE HAPLO-DIPLOID TURNIP SAWFLY *ATHALIA ROSAE* (HYMENOPTERA, TENTHREDINIDAE) ?
T. Naito
Entomology Laboratory, Faculty of Agriculture, Kobe University, Kobe, Japan

A variety of hymenopteran species in taxonomic-ally diverse groups have a single-locus multiple-allele sex determination system and produce diploid males (homozygous for sex alleles) through sister-brother mating in the laboratory. Diploid males usually have been observed at low frequencies and never been functional. In *Athalia rosae* with a single sex locus system, we can get diploid adult males very easily from sister-brother mating without remarkable developmental mortality. However, we can not find any diploid males in the field population. My investigation has revealed that three major factors would act to obstruct the occurrence of diploid males of *A. rosae* in the field:
(1) Females emerge earlier and move out more quickly from the natal patch than their brothers. This would reduce the sib-mating among progeny.
(2) Females, in case of double matings, always use the second-male sperm for daughter production. Therefore, sib-mating, even if occurred in the natal patch, would be cancelled by the second mating with a male of other brood after her short flight.
(3) A large number of sex-alleles (about 50 in the local population near Kobe) would prevent to produce homozygotes for sex alleles in outbreeding in the field.

"COMPLIMENTARY SEX DETERMINATION, MULTIPLE MATING AND SEX ALLOCATION IN THE PARASITOID *DIADEGMA CHYROSTITICOS*."
R. Butcher, W. Whitfield & S. Hubbard.
Dpt. of Biological Sciences, Dundee University, Scotland.

The solitary endoparasitoid *Diadegma chyrostiticus* shows a heavily male biased secondary sex ratio in culture, but not in the field. The establishment of isofemale lines (son x virgin mother mating and subsequent within-sibling brother x sister mating) of *Diadegma chyrostiticus* results in the rapid male bias of subsequent offspring and in the presence of diploid sons when cultured at 24-27°C, in accordance with single locus complementary sex determination (sl-CSD). However, when isofemale lines are maintained at 16-18°C neither the male biased sex ratio nor diploid sons are observed. The presence of sl-CSD is further confirmed by genetic studies using both phenotypic mutants and alloenzyme studies. At both rearing temperatures a marked inbreeding suppression of maternal fecundity is observed. As predicted, outbreeding restores both a normal maternal fecundity and sibling sex ratio in the next generation. Moreover, *Diadegma chyrostiticus* are observed *in vitro* to undergo multiple mating and to be partially pro-ovigenic. The consequences of multiple mating results in a host-dependent increased maternal fecundity but in a further male biased progeny sex ratio and reduced maternal longevity. For this parasitoid the sex ratio is further compounded by an adaptive sex ratio allocation in response to host size, superparasitism and foundress effects-.

OOGENESIS IN LOWER DIPTERANS: POTENTIAL GERM-LINE / SOMA INTERACTIONS AND EMBRYONIC POLARITY
K. Sander
Inst. f. Biologie I (Zoologie), Albert-Ludwigs-Universität, Freiburg i.Br., Germany

Oogenesis in the lower dipterans (Nematocera) differs remarkably in several respects from its brachyceran counterpart (well studied in *Drosophila*). This may be related to peculiarities in embryonic patterning and polarity (see Seminars in Developmental Biology, Vol. 7). Nematoceran oogenesis was therefore studied in the scanty literature and in some psychodid and scatopsid species, in order to help reconstructing evolutionary divergence between the two suborders. In nematocerans, the oocyte-nurse cell complex apparently polarizes without obvious reference to any somatic structure. Only thereafter are the polarized complexes settling in minute aberrant "ovarioles". The somatic follicular epithelium differs in that neither its "centripetal" cells nor the anterior polar cells (border cells in *Drosophila*) reach the anterior face of the oocyte before nurse cell regression is almost complete. Moreover, the border cells produce a massive micropylar structure while still located anterior to the nurse cells. They then carry the micropyle along to the oocyte surface very late in oogenesis; thus oocyte / polar cell interactions can only be brief but might be extended via the micropylar structure (*tsl* storage?). In *Psychoda*, unusual interactions may occur between the spermatozoa and the somatic cells of the ovariole stalk that harbour them in large numbers - perhaps to compensate in some way for sperm immotility?

CHARACTERIZATION OF NEW GENES INVOLVED
IN THE GENERATION OF DORSAL-VENTRAL
AXES OF DROSOPHILA EGG AND EMBRYO

Debiao Zhao¹, Janis Walker² and Mary Bownes²
1. Shanghai Institute of Cell Biology, Chinese Academy of Sciences, P.R. China. 2. Institute of Cell and Molecular Biology, University of Edinburgh, U.K.

Establishment of the dorsal-ventral axes of the *Drosophila* egg and embryo is mediated by two different, but related signal transduction pathways. One is required for the specification of dorsal follicle cell fate during oogenesis and starts with a signal from oocyte and received by the follicle cells on dorsal side. The other, for specification of dorsal-ventral cell fate during embryogenesis, starts with an unknown signal possibly from follicle cells and received by nuclei of the syncytial blastoderm. Using enhancer trap *gal4/UAS* lines, we have identified four distinctive genes which encode 1) HLH negative transcriptional factor, 2) secreted peptide, 3) tyrosine kinase, and 4) new protein. Whole mount ovary in situ hybridization analysis shows that these four genes have two quite different expression pattern. Genes 1 and 3 are expressed specifically in antiodorsal (also posterior for gene 1) follicle cells surrounding the oocyte in the stage 8-10 of oogenesis, while genes 2 and 4 are expressed in the overlaying follicle cells except antiodorsal in the stage 10-11, suggesting their involvement in two different pathways. Examination of their expression in two different mutant, *grk* and *fs(1)K10* background shows corresponding changes, the expression of gene 3 in *fs(1)K10* mutant ovaries expanded from the antiodorsal towards antioventral side, indicating that all of them function downstream of *grk* and *fs(1)K10* in the genetic hierarchy of dorsoventral axis.

04-018

REGULATION OF THE DROSOPHILA MELANOGASTER
VITELLOGENIN RECEPTOR GENE, YOLKLESS, DURING
OOGENESIS.

C. Schonbaum, J. Perrino, A. Mahowald
Dept. of Molecular Genetics and Cell Biology, The University of Chicago
Chicago, IL USA

In *Drosophila melanogaster*, the uptake of yolk proteins into the oocyte only occurs during certain stages of development (stages 8-10). Yolk protein uptake is first seen following the juvenile hormone induced transition from stage 7 to stage 8, while yolk uptake terminates with the completion of the vitelline membrane around the oocyte. In order to determine if regulation of the yolk protein receptor is involved in the control of yolk uptake, we examined the expression of the receptor. The receptor, encoded by the *yolkless* (*yl*) gene, is a member of the low density lipoprotein receptor superfamily.

Whole mount in situ analysis of *yl* RNA and protein revealed that the *yl* gene is expressed very early during the development of the oocyte. *yl* RNA is expressed only in the germline cells (nurse cells and oocyte) and the RNA accumulates in the presumptive oocyte as early as the germinal stages. This localization requires the activity of *BicaudalD* and *egalitarian*, which are involved in differentiating the oocyte from the nurse cells. The oocyte staining of *yl* RNA is observed through stage 8. During later stages, *yl* RNA is detected in both the nurse cells and the oocyte. The Yl protein is also apparent in the germinal stages, early during the development of the oocyte. Yet, in contrast to the *yl* RNA pattern, Yl protein is seen only in the oocyte and not in the nurse cells of later (stage 10) chambers. Thus, *yl* RNA may be translated more efficiently in the oocyte than in the nurse cells. Furthermore, until stage 7, Yl protein is distributed uniformly throughout the oocyte, but following the transition to the vitellogenic stages, Yl becomes progressively more cortical. By stage 10, the protein is almost entirely at the cortex. Immunogold electron microscopy has shown that Yl is associated with the endocytic apparatus (e.g. coated pits, vesicles, tubules). Thus, yolk uptake at stage 8 appears to be regulated through the activation and relocalization of the receptor or other endocytic components.

We are currently examining the promoter elements required for transcription in the germline and we are examining the relocalization of the receptor following the onset of vitellogenesis.

04-017

MOLECULAR ANALYSIS OF RECEPTOR-ENDOCYTIC
MACHINERY IN MOSQUITO OOCYTES

A.S. Raikhel, V.A. Kokoza, T.W. Sappington, and W.L. Cho¹
Department of Entomology, Michigan State University, East Lansing, MI USA - 1 Department of Parasitology, National Yang-Ming University, Shih-pai Taipei, Taiwan

Insect oocytes are highly specialized for receptor-mediated endocytosis of yolk protein precursors, and are characterized by a concentration of endocytic organelles unparalleled in any other cell. To study the biogenesis of the endocytic machinery in mosquito oocytes at the molecular level, we cloned and analyzed cDNAs and genes encoding two major coated vesicle components: 180-kDa clathrin heavy chain (CHC) and 205-kDa vitellogenin receptor (VgR). In the mosquito CHC gene, which spans more than 25 kb, the coding region is divided into seven exons, five of which encode the protein. Alternative first exons are used differentially for the oocyte-specific and somatic transcripts. Although the 3'-untranslated regions of both these transcripts are encoded by the same last exon, located 12 kb apart from others, the 3' region of the somatic 7.5-kb transcript is 1 kb longer than that of the oocyte-specific 6.5-kb transcript. The structure of the 3'-untranslated regions suggests that the oocyte-specific transcript is more stable than the somatic transcript. The 7.3-kb VgR cDNA encodes a 203-kDa protein which belongs to the low-density-lipoprotein receptor family. In situ hybridization, Northern, and slot-blot analyses shows that these genes are expressed similarly: both CHC and VgR transcripts are evident in the germ cells very early during differentiation of primary and secondary follicles. In pre- and vitellogenic follicles, the transcripts were present in very high concentration in developing oocytes and only in trace amount in nurse cells.

04-019

SOMATIC CELL AND GERM CELL REGULATION OF OOGENESIS IN
PHORMIA REGINA (MEIGEN)

C.-M. Yin, J.G. Stoffolano, Jr.
Department of Entomology, University of Massachusetts, Amherst, MA USA

In the black blow fly, *Phormia regina*, oogenesis is regulated by factors (or actions) from both somatic and germ cells like in the case of other insects. These cells include median neurosecretory cells of the pars intercerebralis, corpus allatum cells, fat body cells, follicular cells, and the oocyte itself. More recently, we have discovered that endocrine cells in the midgut will secrete substances into the hemolymph in liver-fed flies 6 h after the protein meal.

The sequence of events and the action of the involved cells are described below. A protein meal will cause the release of substances from the midgut. Results suggested that two substances are released simultaneously. Both substances can stimulate oogenesis in the bioassay our used. Two hours after the release of these midgut substances, the volume of the median neurosecretory cells (A-type) increased to the maximum before decreased to the pre-protein meal level 4 h later. It appeared that this neurosecretory activity, as reflected by the volume change of A-cells, in turn turned on the ecdysteroid production/release by the ovaries and the juvenoid production/release by the corpus allatum.

In response to ovarian ecdysteroid, competent fat body cells produce/secrete vitellogenin into the hemolymph. In response to juvenoids, follicle cells change shape to make intercellular space (patency). Meanwhile, oocytes begin to produce vitellogenin receptor which is required to form the vitellogenin-specific coated pits to allow endocytosis of vitellogenin into the developing oocyte. What governs the production of vitellogenin receptor is unclear in *P. regina*. It is obvious that we have long way to go before fully understand all the mechanisms governing oogenesis in this blow fly.

04-020

ORIGINS OF ANTERIOR-POSTERIOR AND DORSAL-VENTRAL POLARITY DURING OOGENESIS IN DROSOPHILA

S. Roth¹ and T. Schüpbach²

¹ Max-Planck-Institut für Entwicklungsbiologie, Tübingen, FRG
² Department of Molecular Biology, Princeton University, Princeton, USA

In *Drosophila*, the dorsal-ventral polarity of the egg chamber depends on the localization of the oocyte nucleus and the *gurken* RNA to the dorsal-anterior corner of the oocyte. The TGF α -like *gurken* protein presumably acts as a ligand for the *Drosophila* EGF receptor (*torpedo/DER*) expressed in the somatic follicle cells which surround the oocyte. We have identified *cornichon*, a new gene required in the germline for *gurken-torpedo* signaling. A phenotypic analysis reveals that, in addition to their role in dorsal-ventral patterning, *cornichon*, as well as *gurken* and *torpedo*, are required in an early signaling event between oocyte and posterior follicle cells which establishes the anterior-posterior polarity of the egg chamber. Mutations in all three genes prevent the formation of a correctly polarized microtubule cytoskeleton required for proper localization of the anterior and posterior determinants, *bicoid* and *oskar*, and for the asymmetric positioning of the oocyte nucleus. Therefore, *cornichon-gurken-torpedo* signaling is not only required to transmit the primary dorsal-ventral polarity established by the asymmetric positioning of the oocyte nucleus, but the signaling itself is a prerequisite to generate the primary dorsal-ventral polarity. We plan to clone *gurken* from other insect and arthropod species to study the evolution of primary axis formation and its relation to different types of oogenesis.

04-021

Interaction of the morphogens Bicoid and Hunchback in patterning the anterior of *Drosophila melanogaster* (Meigen)

E. A. Wimmer, M. Simpson-Brose, A. Wong, & C. Desplan

Howard Hughes Medical Institute, The Rockefeller University, New York, U.S.A.

Removal of maternal and zygotic *hunchback* (*hb*) activity by a molecular genetic approach, localizing *nanos* RNA at the anterior pole (BBNH system), has suggested that a synergistic interaction between *hb* and *bicoid* (*bcd*) is required for anterior patterning of the *Drosophila* embryo. However, generating germline mosaic clones by the "flipase-dominant female sterile" (FLP-DFS) technique shows that *hb* activity is not necessary for anterior development.

These contradicting results can be due to different levels of *bcd* activity in the two systems, since the BBNH system interferes with it, whereas the FLP-DFS technique does not. To test the hypothesis that the interaction between *bcd* and *hb* becomes only apparent at reduced levels of *bcd* activity, we removed both *bcd* and *hb* activities with the FLP-DFS technique and varied the level of *bcd* activity by the introduction of transgenes.

Our results indicate that wildtype levels of *bcd* activity are sufficient to pattern the anterior even in the absence of *hb* activity. However, in a situation where the *bcd* activity level is reduced to a degree that it is itself insufficient to organize anterior development, *hb* activity can provide additional organizing function to rescue anterior patterning. Bicoid and Hunchback are therefore indeed able to synergize with each other in order to organize anterior development, despite that in a wildtype embryo this interaction is not required for it.

PATTERN FORMATION IN POLYEMBRYONIC DEVELOPMENT: HOW IS THE INSECT BODY PLAN ESTABLISHED WITHOUT THE SYNCYTIIUM?

M. Grbic, L. Nagy, S. Carroll, M. Strand, Developmental Biology Program University of Wisconsin, Madison WI 53706

Development of the polyembryonic parasitic wasp *Copidosoma floridanum*, which develops up to 2000 individuals from the single egg, dramatically deviates from the general pattern of insect development. It is unclear how an individual embryo is patterned in such an extreme form of embryogenesis. To understand the mechanisms behind polyembryonic development we first described the embryonic development of *C. floridanum* using cell labeling, phalloidin and nuclear staining. We also examined the expression of homologues of the *Drosophila* segmentation genes *even-skipped*, *engrailed* and *Ultrabithorax/Abdominal A* using monoclonal antibodies.

We have found that complete cellularisation in *C. floridanum* embryonic development takes place early in development and that each individual embryo develops from a cellularised embryonic primordium and does not have a syncytium. Eve antigen was first expressed as homogenous domain in the blastula stage embryo, from the posterior to 3/4 the length of the blastula. Following gastrulation, stripes were sequentially formed from anterior to posterior, and the expression corresponded to a segment polarity pattern and not to the pair-rule pattern described in *Drosophila*. The pair-rule expression of Eve has likely been secondarily lost in polyembryonic insects, as a consequence of establishing segmental pattern in a cellularized environment. En antigen was expressed in an anterior-to-posterior progression, without pair-rule modulation characteristic for *Drosophila*. In addition, the En expression domains overlapped with the mature Eve stripes *Ubx/Abd A* was detected in the phylotypic stage of development in the putative abdominal region, and had a conserved pattern of expression. Our results indicate that neither a syncytium nor the formation of double-segments with Even-skipped is required for segmental patterning in insects. Experiments are currently in progress to analyse pattern formation upstream of pair-rule cascade.

BIOSYNTHESIS AND ENDOCYTOSIS OF MOSQUITO VITELLOGENIN: CLONING OF PRO-VITELLOGENIN CLEAVAGE CONVERTASE AND VITELLOGENIN RECEPTOR cDNAs

A.S. Raikhel, T.W. Sappington, J.S. Chen, and W.L. Cho¹
Department of Entomology, Michigan State University, East Lansing, MI USA · 1 Department of Parasitology, National Yang-Ming University, Shih-pai Taipei, Taiwan

The cornerstone of insect egg maturation is massive secretion of vitellogenin (Vg), and its specific accumulation by oocytes. In the mosquito fat body, a single Vg precursor (pro-Vg) is cleaved into small and large subunits. The cleavage site of pro-Vg contains the paired-basic motif, RX(K/R)R, the recognition sequence for eukaryotic convertases. To identify the insect Vg cleavage enzyme, a cDNA encoding Vg convertase (VC) was cloned from the mosquito, *Aedes aegypti*. The 3,735 bp-long VC cDNA encodes a 115-kDa protein with high similarity to, and a domain structure typical of, furin-like convertases. Co-expression of this VC cDNA with the truncated mosquito Vg cDNA resulted in correct cleavage of pro-Vg. A 4.2-kb VC transcript is expressed in the vitellogenic fat body.

The 205-kDa vitellogenin receptor (VgR) is a key oocyte-specific molecule which mediates internalization of its ligand, Vg. Following purification and microsequencing, we cloned two cDNA fragments that encompass the entire VgR coding region. The mosquito VgR deduced amino acid sequence reveals a modular arrangement typical of the low-density-lipoprotein receptor family and shares significant homology with the chicken VgR. The mosquito VgR shows even greater homology to the *Drosophila* yolk protein receptor, in spite of their respective ligands being unrelated.

EVOLUTIONARY CONSERVATION AND DIVERGENCE OF DROSOPHILA SEGMENTATION GENES IN INSECTS

D. Tauts (Munich-Germany)

ABSTRACT NOT RECEIVED

04-027

REGULATION OF YOLK PROTEIN GENE EXPRESSION IN DROSOPHILA MELANOGASTER

S. Hutson, D. Mauchline, E. Ronaldson and M. Bownes.
Institute of Cell and Molecular Biology, University of Edinburgh, Edinburgh, UK.

The three yolk protein genes (*yp1*, *yp2* and *yp3*) of *Drosophila melanogaster* are expressed in the adult female fat body and in the follicle cells at specific stages of oogenesis. Expression in the fat body depends upon the sex-determination pathway, the hormones 20-hydroxyecdysone (20-OHE) and juvenile hormone, the nutritional status of the fly and tissue specific factors. We will describe the results of experiments using P-element mediated transformation to investigate the cis-acting sequences required for the regulation of *yp* gene expression in the fat body. Sequences have been identified 5' of the genes which confer their tissue and sex specific expression in the fat body. Regions responsive to ecdysteroids are located 5', within the coding region and 3' of the gene.

The sex determination gene, *doublesex*, has been shown to bind to one of the cis-acting sites that directs sex-specific for the body expression of *yp1* and *yp2* (Burtis *et al* 1991, EMBO J 10: 2577). 3 other trans-acting functions bind *in vitro*, namely AEF, BBF-2 and C/EBP (Falb and Maniatis 1992, Genes Dev 6: 454) to the same DNA fragment. It is not known whether 20-OHE and its receptor act directly or indirectly on these genes. We present evidence on the mode of action of 20-OHE and show that not all of the factors which bind *in vitro* to sequences flanking the *yp* genes have a role to play *in vivo*.

FATE OF YOLK PROTEINS DURING EMBRYOGENESIS IN LEPIDOPTERA

Susumu Y. Takahashi *, Yoshimi Yamamoto*, Xiaofan Zhao ** and Shoji Watabe***.

*Department of Biology, Faculty of Liberal Arts, Yamaguchi University, Yamaguchi 753, Japan. ** Department of Biology, Shandong University, Jinan, Shandong, P.R.China.

*** Radioisotopes Laboratory, Yamaguchi University, Yamaguchi 753, Japan.

The role of egg proteinases in insects appear to be primarily for utilization and mobilization of yolk proteins during embryogenesis. To prevent inappropriate and uncontrolled degradation of yolk proteins and to accomplish the aims of supplying amino acids for synthesis of embryonic proteins, proteolytic activity in developing eggs are a highly regulated process, whereas despite the importance of the process, the regulatory mechanism of yolk protein degradation still remains to be solved. Very recently, we have purified cathepsin L-like proteinase (BCP) from *Bombyx* eggs and two cathepsin B-like proteinases from *Antheraea* and *Samia* eggs (ACP & SCP). They are all synthesized in extra ovarian tissues (fat bodies and follicle cells) under the control of ecdysone, and stored in the oocytes as a latent inactive proenzymes. In the case of *Bombyx* eggs, these were confirmed by means of *in vitro* translation of RNA and Northern blot analysis using cDNA as a probe. Immunohistochemical experiments also suggest this possibility. During embryogenesis, cysteine proteinases are activated by limited proteolysis. BCP is activated autocatalytic manner, and ACP and SCP required another enzymes for their activation. In order to learn more about the mechanism of activation, recombinant proBCP as well as intermediate forms of the proteinase during activation was prepared and the mechanism of activation was compared with that of purified proBCP. In this symposium, we will discuss about proteinases in the eggs of lepidopterous insects, which include biosynthesis, accumulation in the ovary, mechanism of activation, and regulatory mechanism of yolk protein degradation during embryogenesis, with special emphasis on recent results obtained from the silkworm, *Bombyx mori*.

04-029

THE PURIFICATION AND CHARACTERIZATION OF A CATHEPSIN B-LIKE PROTEINASE FROM THE EGGS OF TUSSAH, *ANTHERAEA PERNYI*Xiao-fan Zhao¹, Jin-xing Wang¹, S. Y. Takahashi², Y. Yamamoto²¹ Department of Biology, Shandong University, Jinan, P. R. China-2 Department of Biology, Faculty of Liberal Arts, Yamaguchi University, Yamaguchi, Japan

Several types of egg proteinases have been reported in insects, for example, both cysteine and serine proteinases are found in *Bombyx mori*. However, whether these proteinases exist widely and act with the same mechanism in the eggs of all Lepidoptera has not yet been determined. Recently, a cathepsin B-like proteinase was identified in the eggs of *Antheraea pernyi*. Furthermore, the enzyme was purified by chromatography. The molecular mass of the proteinase was estimated to be 47 kDa by sodium dodecylsulfate-polyacrylamide gel electrophoresis (SDS-PAGE), and 160 kDa by Sepharose CL-6B gel filtration, suggesting that the proteinase is a tetramer. The activity of the purified proteinase was strongly inhibited by N-[N-(1,3-trans-carboxyoxiran-2-carbonyl)-L-leucyl]-agmatine (E-64) and leupeptin. The pH optimum was 3.5 as determined using the bovine hemoglobin as the substrate. The results of SDS-PAGE showed that the vitellin was the main component of the yolk proteins, while the amount of 30 K protein was very low in *Antheraea pernyi*. The antisera to vitellin from *A. pernyi* could recognize vitellin from *Philosamia cynthia ricini*. Antisera to cathepsin B-like proteinase from *A. pernyi* also cross reacted with the antigen from *P. c. ricini*, which indicated out the similarities on the enzymes and substrates *in vivo* between these two species.

04-030

A COMPARATIVE ANALYSIS OF ANIMAL VITELLOGENIN GENESH. H. Hagedorn, Z. Tu and D.R. Maddison
Department of Entomology and Center for
Insect Science, University of Arizona,
Tucson, AZ USA

Sequences for 17 vitellogenin genes, from 12 different species including 6 insects, are now available. Comparison of the deduced amino acid sequences has shown that they are members of a multigene family. A conserved region has been identified that is common to the vitellogenin genes of three insects, the nematode and the vertebrates. This conserved region also aligns with the Cycloraphid Dipteran yolk proteins, lipases and an α -helix-rich sequence in the lamprey vitellogenin gene. We hypothesize that several gene duplications gave rise to the vitellogenin gene family and that the yolk proteins of the Cycloraphid Diptera were derived from the other animal vitellogenin genes.

04-031

PURIFICATION AND PARTIAL CHARACTERIZATION OF VITELLIN(S) OF THE RED COTTON STAINER, *Dysdercus koenigii***Venugopal, K.J.** and Dinesh Kumar

Department of Zoology, Banaras Hindu University, Varanasi-221 005, India

The predominant yolk protein(s), vitelin(s), were purified from freshly laid eggs by high salt extraction and low salt precipitation followed by gel-filtration and ion-exchange chromatography. Vitellin(s) eluted in gradient NaCl as two distinct peaks (Vitelin A-VnA- of approximate mol. wt. 290 k Da and vitelin B-VnB- of approximate mol. wt. 260 k Da)

Native PAGE of VnA and vnB displayed single bands of respective Rf values 0.17 and 0.25, both corresponding to different proteins of the crude egg extract which revealed 4 bands of Rf values 0.12, 0.17, 0.25 and 0.28. Both the vitellins were glycolipoproteins as exhibited by their staining nature.

VnA and VnB had similar electrophoretic behaviour in SDS-PAGE in which VnA resolved into 3 polypeptides (mol. wt. Ca. 116, 92, 62 k Da) and vnB into 4 with an additional 40 k Da polypeptide; all the sub units staining positive for carbohydrates and lipids. Both the vitellins lacked interchain disulfide linkage.

Immunodiffusion tests conducted using polyclonal antibodies raised separately against the vitellins showed their mutual immunological identity. The antivitelin antisera cross reacted with mated, vitellogenic, female fat body, haemolymph and ovary but did not show any reaction with mated or 5th instar female fatbody or haemolymph exhibiting their sex and stage specificity.

04-032

CHANGES IN PATENCY AND FOLLICULAR VITELLIN CONTENT IN *Tenebrio molitor* INFECTED WITH *HYMENOLEPIS DIMINUTA***T.J. Webb, K. Ellams and H. Hurd**

Centre for Applied Entomology and Parasitology, Department of Biological Sciences, Keele University, Keele, Staffs. ST5 5BG. U.K.

Fecundity depletion in *Hymenolepis diminuta*-infected *Tenebrio molitor* is associated with a severe disruption in vitellogenesis, leading to decreased egg production and viability. Although the titre of juvenile hormone, which is known to coordinate these events, is unaltered, binding of the hormone to follicle cell sites is reduced. Thus, patency is delayed and the passage of vitellogenin to the oolemma is hindered. In an effort to determine whether these changes may be due to a juvenile hormone binding inhibitor, patency studies have been carried out at day 3 post-infection. The results suggest that the patency index of follicles from infected insects increases to control values after *in vitro* incubation (26°C; 6h; 3 changes of medium), and hence, the possible removal of inhibitory substances. ELISA detection of vitellin in 6 size ranges of follicles (0-1000µm in length) indicated that depreciations in yolk protein content are most marked in follicles of <200µm and early in the infection (day 3; 77.5% reduction): follicles appear to attain the correct length, but contain significantly less vitellin.

04-033

EFFECT OF THE ADULT FEEDING AND ENDOCRINE ON THE VITELLOGENESIS AND OVARY DEVELOPMENT IN THE ORIENTAL ARMYWORM *MYTHIMNA SEPERATA* WALKER (LEPIDOPTERA : NOCTUIDAE)**H.Gong, C.Cao**

Institute of Zoology, Academia Sinica, Beijing, China

The yolk protein was prepared from the matured eggs by extraction with PBS buffer and subsequent precipitation in cold distilled water. The molecular weight of the native vitellin was determined as 205 Kd and the two subunits with molecular weights 142Kd, 47Kd by SDS-PAGE. The total protein contents and yolk protein titer of the hemolymph, fat body and ovary during the adult reproductive period was monitored by SDS-PAGE, rocket immuno-electrophoresis and protein assay.

In adult allatectomized within 24h after eclosion, the vitellogenin could not be detected in hemolymph and the ovary could not develop during the adult stage. JHA could restore the vitellogenesis and ovary development. The facts showed the JH served as a key factor to regulate vitellogenesis and ovary maturation during the reproductive stage. To test whether feeding behavior or nutrition effect on vitellogenesis and ovary development. It was exhibited that the initiation of the vitellogenin synthesis did not depend on the nutrition or feeding behavior, the activating of the CA was neither related to the nutrition during the adult stage nor the action of adult feeding, but adult feeding was required for the continual maturation to amount of eggs. So the effect of the nutrition on the vitellogenesis and ovary development may be through that nutrition promotes the endocrine activity.

04-034

YOLK PROTEIN DEGRADATION IN *HYALOPHORA CECROPIA* EMBRYOS.**E.C. Rubenstein, Y. Sharma, and A.A. Silver**

Department of Biology, Skidmore College, Saratoga Springs, NY, USA

Yolk proteins stored in developing insect oocytes are subsequently degraded during embryogenesis. In embryos of the giant silkworm *Hyalophora cecropia*, the yolk proteins are processed into smaller, immunoreactive peptides before complete breakdown. Degradation of the four principal yolk proteins is slow initially, but increases dramatically by day 11 of a 13 day developmental period. This is apparent in stained gels of a developmental series of embryonic extracts, as well as in Western blots for specific yolk proteins. Using zymography, we have identified several proteases that are not detectable in embryo homogenates earlier than day 11. The proteases detected differ with regard to specificity for the two substrates tested and optimum pH for detection. Auto-digestion studies of embryo homogenates at different pH values suggest that the major proteolytic activity responsible for the degradation of vitellin, the major yolk protein, is not present in the embryo until the last two days of development.

04-035

DEVELOPMENT OF THE WING BUDS IN *MEGOURA VICIAE* BUKT. (HOMOPTERA: APHIDIDAE).

L. Mola, G. Signa, G. Barozzi, I. Benedetti, A. M. Bonvicini Pagliai

Dipartimento di Biologia Animale, Università di Modena, Modena, Italy

Previous investigations (Benedetti et al., 1991) have demonstrated that the wing buds in both males and females of *Megoura viciae* and *Acyrtosiphon pisum* are already present two days before birth. The morphological study was extended to parthenogenetic females and to males of *M. viciae* from birth (time 0) to IV instar.

In males, the wing bud epithelium is initially monostratified, becoming bistratified and then progressing to polystratified. Mitotic activity is more intense in the proximal bud, and its behaviour seems to synchronous and follows successive cycles.

TEM observations of the zone between the two buds, which in the adult will become two wings, show small cells lacking mitotic activity. Moreover, from birth to II instar, numerous vacuoles become evident in the wing epithelium.

In parthenogenetic females, which are presumably wingless, the buds resemble those of males from birth to II instar; subsequently, the wing epithelium returns to the monostratified state, and in the IV instar, it cannot be distinguished from the adjacent epithelium.

These observations, in addition to describing for the first time the initial phases of wing morphogenesis, define distinctive features of the wing bud that can be used to identify the presence or absence of these buds during development in other Aphid species.

04-037

A HORMONE FROM THE TSETSE FLY UTERUS STIMULATES PARTURITION AND ABORTION

D.L. Denlinger and J. Zdarek¹

Department of Entomology, Ohio State University, 1735 Neil Avenue, Columbus, Ohio 43210, USA -

¹ Institute of Organic Chemistry and Biochemistry, Academy of Sciences of the Czech Republic, Prague, Czech Republic

Unlike most insects, the tsetse female gives birth to a single, fully-grown larva at the culmination of each pregnancy cycle. The expulsion of the larva is regulated by a hormone present in rich abundance within the female's uterus. The hormone elicits parturition when injected into neck-ligated females at late stages of pregnancy and abortion when injected at earlier stages. We refer to this highly active material (0.043 uterus equivalents stimulates parturition in 50% of the females) as parturition hormone. Injection of the active extract, which appears to be a peptide or small protein, initiates the series of blood pressure pulsations and uterine contractions normally associated with parturition. The discovery that a uterus extract from the flesh fly also elicits parturition in tsetse suggests that this hormone may be widely distributed in insects.

04-036

THE RELATIONSHIP BETWEEN WING FORM AND FLIGHT MUSCLE DEVELOPMENT IN THE ORIENTAL CHINCH BUG *CAVELERIUS SACCHARIVORUS* OKAJIMA (HETEROPTERA, LYGAEIDAE)

Kenji Fujisaki

Faculty of Agriculture, Okayama University, Tsushima-naka, Okayama 700, Japan

The relationship between wing form and flight muscle development was investigated for the adults of the oriental chinch bug, *Cavelerius saccharivorus*, which is an important pest of sugar cane in the subtropical region in Japan. As a result, it was found that there is a positive correlation between the relative wing length (RWL) and the % of retaining the fully developed flight muscles in both sexes. Almost all of the brachypters with RWL of 3.5-4.0 had undeveloped flight muscles, while a considerable portion of macropters with RWL more than 4.5 had fully developed flight muscles. The macropters with RWL of 4.5 were intermediate in the developmental degree of flight muscles. However, it should be noted here that some of the macropters did not have fully developed flight muscles. This indicates that some of the macropters of this species can not necessarily fly.

Based on the above results, the adults of *C. saccharivorus* were classified into three groups; adults with undeveloped wings and flight muscles, adults with developed wings and undeveloped flight muscles, and adults with developed wings and flight muscles. These phenomena were explained by the difference in the threshold level of response to any effectors such as JH between wing form determination and flight muscle form determination.

04-038

PHOTOPERIODISM AND THE ENDOCRINE ASPECTS OF ADULT DIAPAUSE IN *PROTOPHORMIA TERRAENOVAE*

H. Numata, S. Shiga, J. Matsuo

Department of Biology, Faculty of Science, Osaka City University, Osaka, Japan

Protophormia terraenovae (Robineau-Desvoidy) (Diptera: Calliphoridae) showed a long-day photoperiodic response: Adults began to reproduce promptly after emergence under long-day conditions, whereas under short-day conditions they entered diapause without vitellogenesis. Temperature also showed a notable effect on the induction of diapause.

Removal of the corpus allatum (CA) inhibited ovarian development in nondiapaused adults. After application of a juvenile hormone analogue, implantation of the CA, or cutting of the nervi corporis allati in diapause adults, the adults fully developed their ovaries. Thus an inactivity of the CA to secrete juvenile hormone induces adult diapause in *P. terraenovae* and the CA activity is inhibited by the brain by way of the nervi corporis allati.

When the compound eyes were bilaterally covered by silver-containing paint, most of the flies entered diapause even under a long-day photoperiod or continuous light. These results show that *P. terraenovae* perceives photoperiod through its compound eyes.

04-039

ACTIVITY OF Mg^{2+} -DEPENDENT DEOXYRIBONUCLEASE IN ONTOGENESIS OF THE COLORADO POTATO BEETLE *LEPTINOTARSA DECEMLINEATA* SAY

S.A. Borodin

Laboratory of Insect Biochemistry, Department of Organic and Biological Chemistry, Moscow State Pedagogical University, Moscow, Russia

The activity of Mg^{2+} -dependent DNAase of the Colorado beetle was shown to depend on the morpho-functional state of the organism. The most marked changes in the dynamics of total activity of Mg^{2+} -dependent DNAase were noted in the physiologically active beetle, i.e. during the period of growth and development, metamorphosis, feeding and reproduction. The enhancement of the deoxyribonuclease reaction is characteristic before every larval moult, its highest intensity has been observed in the end of the IV instar. The least level of DNAase activity was found in eggs. The dynamics of total activity of Mg^{2+} -dependent DNAase no marked changes in the state of winter rest (winter diapause, oligopause and spring res-toration period).

04-041

ARTIFICIAL DIETS FOR CITRUS-FEEDING SWALLOWTAIL BUTTERFLIES (LEPIDOPTERA: PAPILIONIDAE)

T. A. INOUE, H. SHINBO

National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan

Citrus-feeding swallowtail butterflies, Genus *Papilio*, have been utilized as materials for various experimental purposes in the biological sciences as well as exhibits in museums or insectariums. We developed artificial diets for the butterflies by modifying those for the silkworm, *Bombyx mori*, for the use of the insects as experimental animals throughout the year.

The artificial diets contained 50% of leaf powder of *Fagara arisanthoides*, on a dry weight basis. The fresh leaves were dried by employing three different procedures; (1) freeze drying, (2) drying at 90°C completely, and (3) drying at 90°C after steaming for 5 minutes. *Papilio xuthus*, *P. protenor*, *P. polytes* were used for the experiment. Each ten newly hatched larvae were confined in a plastic cup (10ml) with small amount of the diet. Eggs, larvae and pupae were maintained at 25±2°C, 50~60% RH, and under a long day photoperiod(16L:8D).

It was evident that the drying condition influences largely the food values of *Fagara arisanthoides* leaves. Relatively good growth was obtained in all the species on the diets containing the leaf powder dried after steaming, while a very poor growth was obtained on those containing the leaf powder dried without steaming or freeze-dried. The mortality was very high during the first instar larval stage compared to that during the other instar larval stage. We observed that the decrease of survival during the stage from the 2nd to last instars was mainly caused by devouring. The weight of the pupa and size of the adults were almost the same as those of insect reared on fresh leaves. We also confirmed the fertility of the butterflies reared on these artificial diets. Some other species belonging to Genus *Papilio* also could be reared on these artificial diets, although their fertility has not been confirmed.

04-040

NUTRITIONAL INDICES OF SECOND INSTAR LARVAE OF *PLUTELLA XYLOSTELLA* L. FED UPON LEAVES TREATED WITH EXTRACT FRACTIONS AND ISOLATES OF *MELIA AZEDARACH* L.

S.S. Sandhu and Darshan Singh

Department of Entomology,

Punjab Agricultural University, Ludhiana, India.

Nutritional indices like relative growth rate (RGR), efficiencies of conversion of ingested food (ECI) and conversion of digested food (ECD) showed a linear decreasing trend over solvent check, on increasing concentration from 0.0125 to 0.05% of chloroform : methanol (9:1) crude extract of *Melia azedarach* L. and its hexane, diethylether, ethyl acetate and chloroform fractions against second instar larvae of *Plutella xylostella* L. After four days of exposure, significantly less food was consumed and larval weight gained was lower by 1.5 times. The relative consumption rate (RCR) remained unaffected except in chloroform and crude extract (both @ 0.05%). In hexane, chloroform and crude extract, ECI and ECD indices were reduced to their lowest and ranged from 40.3 to 43.6% and 41.7 to 45.2%, respectively as compared with other treatments (ECI = 48.7 to 48.9%; ECD = 50.8 to 52.2%) and the solvent check (ECI = 56.9 to 60.0; ECD = 58.3 to 61.6%).

In gedunin and ochinolid-B treatments, food consumed and weight gained by the larvae was greatly reduced. RGR was reduced from 0.56 in solvent check to 0.39 in gedunin and 0.40 in ochinolid-B (both @ 0.005%). ECI and ECD indices were also significantly reduced in these treatments.

04-042

SOLID ARTIFICIAL DIET WITH TOMATO JUICE FOR LARVAE OF *BACTROCERA OLEAE* (DIPTERA: TEPHRITIDAE)E. I. Navrozidis¹ and M. E. Tzanakakis²

1. Plant Protection Institute of Thessaloniki, National Agricultural Research Foundation, 570 01 Themi, Thessaloniki - Greece. - 2. Laboratory of Applied Zoology and Parasitology, Faculty of Geotechnical Sciences, Aristotelian University of Thessaloniki, 540 06 Thessaloniki, Greece.

Larvae of *Bactrocera oleae* (Gmelin) (Diptera, Tephritidae) were reared on a reference artificial diet P, in which the water was replaced by canned tomato juice, and the nutritive components were gradually reduced or omitted altogether one by one.

The diet finally selected was without olive oil, Tween-80 and hydrolysed protein, and consisted of: tomato juice 55 ml, cellulose powder 26 g, brewer's 7.5 g, roasted peanuts 3 g, potassium sorbate 0.05 g, methyl-p-hydroxybenzoate 0.2 g and HCl 2N 2 ml to a pH of 4.

The yield of this simpler diet in adults over neonate larvae was 73.8 %, the mean pupal weight 7.1 mg and larval development was completed in 9.5 days at 25±1°C. The cost of ingredients was approximately 15% lower than that of the reference diet P.

04-043

SXL HOMOLOGUE IN *CERATITIS CAPITATA*: *CcSXL* TRANSGENIC *DROSOPHILAS* AS A TOOL TO STUDY THE CONSERVATION OF FUNCTIONAL DOMAINS.

I. Peluso, G. Saccone, M. Furia and L.C. Polito.

Dipartimento di Genetica, Biologia Generale e Molecolare, Università "Federico II" di Napoli, Italy

The molecular bases of sex determination in dipterans are widely unknown. However, it is possible that a common principle exists, according to which different primary signals control the activity of a binary switch gene (Nöthiger and Steinmann-Zwicky, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 615-621).

In *Drosophila*, *Sex-lethal* (*Sxl*) is the master regulator gene responding to the X:A primary signal and its activity leads to female development. To ascertain whether in *C. capitata* a similar sex-differentiation molecular pathway was employed in spite of the different sex-determining primary signals, we underwent the study of the evolutionary conservation of the *Sxl* gene in this organism.

On the basis of the analysis of several *C. capitata* cDNA clones we established that the *Sxl* gene is highly conserved at the nucleotidic sequence level. However, *CcSxl* is not sex-specifically expressed. To test whether the ectopic expression of *CcSxl* in *Drosophila* males was able to induce sex-specific lethality or sexual transformation, *CcSxl* cDNAs were placed under the control of the *hsp70* promoter and introduced into *Drosophila* germline by *P* element-mediated transformation. A collection of 0-12 h transgenic embryos was heat-shocked and stained with anti-SXL antibody, to check the expression of CcSXL protein. At the phenotypic level, we observed an abnormal differentiation of external male-specific structures in different *Drosophila* transgenic lines, suggesting that CcSXL protein can interfere to some extent with the sex-specific splicing of the downstream sex-differentiation gene (*transformer*). Further studies are currently underway to investigate the effect of the ectopic expression of *CcSxl* in different *Sxl* mutant backgrounds.

04-045

EFFECTS OF WING AMPUTATION, BODY SCORCHING, AND PREVENTION OF FLIGHT ON OVARIAN MATURATION IN THE OLIVE FRUIT FLY *BACTROCERA* (*DACUS*) *OLEAE* (DIPTERA: TEPHRITIDAE)

D.S. Koveos, G.D. Broufas, E. Kiliarakis and M.E. Tzanakakis

Laboratory of Applied Zoology and Parasitology, University of Thessaloniki, 540 06 Thessaloniki, Greece

Ovarian maturation is prevented in *Bactrocera* (*Dacus*) *oleae* (Gmelin) developed in the pre-imaginal stages at LD 12:12, 19±1°C and kept as adults at LD 16:8, 26±1°C. When females developed and maintained under these conditions had their wings amputated or cut off at half their length, or their thoracic notum cauterized, at an early age, a high percent of them had mature oocytes one or two weeks after treatment. Cutting off the halteres, which did not prevent flying, resulted in an intermediate effect between the females with amputated wings and those of the control. The younger the females at treatment, the stronger the favorable effect on ovarian maturation. Females with their wings amputated, laid more eggs in olive fruit during their first 3 weeks than untreated females. Intact females kept during their third week in narrow vials where flying was not possible, soon matured their oocytes in contrast to the control.

04-044

PROSTAGLANDIN E2 IN THE SILKMOTH, *BOMBYX MORI*, WITH SPECIAL REFERENCE TO THE STIMULATION OF EGG-LAYING

H. Fugo, M. Yamauchi, S.G. Dedos

Laboratory of Biochemistry and Physiology of Insects, Tokyo University of Agriculture and Technology, Fuchu-shi, Tokyo 183, Japan

Investigation of the role of prostaglandins (PGs) in the reproductive behaviour of *Bombyx* revealed that PGs play no crucial role as oviposition behaviour stimulants. Injection of prostaglandin E2 (PGE2) had no effect on the egg-laying behaviour of virgin females. Oviposition behavior of females injected with PG biosynthesis inhibitors such as indomethacin, quinacrine and NDGA was not interrupted or suppressed. Sterilized males of *Bombyx* can be induced by heat treatment (32°C) for 72 hrs during their wandering stage. The rate of oviposition of female moths mated with sterilized males was quite suppressed, compared to the control, in the 24 hrs ensuing mating. PGE2 injection on the females mated with these sterilized males had no effect on restoring oviposition behaviour. There were no significant differences in the PGE2 content of testes between normal and sterilized males. After mating, the amount of PGE2 increased with either normal or sterilized males. These results indicate that PGs do not seem to be directly involved in the egg-laying behaviour of *Bombyx*, although PGs may have some functions in the reproduction of this insect.

04-046

REPRODUCTION AND SURVIVAL OF ADULT *DACUS* (*BACTROCERA*) *OLEAE* (GMELIN) (DIPTERA: TEPHRITIDAE) AFFECTED BY DIETARY ADMINISTRATION OF ANTIAMINOACIDS

E.N. Zografou, G.J. Tsiropoulos, L.H. Margaritis¹

Biology Institute, National Center for Scientific Research "Demokritos", Athens 153 10, Greece - ¹ Department of Biology, Division of Biochemistry, Cell-Molecular Biology and Genetics, Athens University, Greece

From a series of 30 anti-amino acids, added individually to the adult diet of *Dacus* (*Bactrocera*) *oleae*, the following ten were significantly shortened the life span of both sexes: L-canavanine (arg), 3,4-Dihydro-DL-proline (pro), L-glutamic acid-γ-hydrazide (gln), D-cycloserine (ala), L-methionine sulfoximine (met) and DL-p-fluorophenylalanine (phe). The parentheses indicate the antagonized normal amino acids. In low concentrations these substances reduced the fecundity, without any significant decrease in hatchability.

Female fecundity and egg hatchability were significantly affected, up to zero, by the following three anti-amino acids: 4-amino-DL(L)-phenylalanine (phe), Allyl-glycine (cys) and 3-amino-L-tyrosine (tyr).

04-047

THE MALE REPRODUCTIVE SYSTEM OF *TENEBRIO MOLITOR* IS AFFECTED BY THE PRESENCE OF *HYMENOLEPIS DIMINUTA* (CESTODA) METACESTODES.

F. Carver & H. Hurd

Centre for Applied Entomology and Parasitology, Department of Biological Sciences, Keele University, Staffordshire, ST5 5BG, UK.

Hymenolepis diminuta is known to adversely affect the reproduction of female intermediate hosts. This is the first study of the effects on male reproduction. Initial studies were focused on the bean-shaped accessory glands (BAGs). The size, weight, trehalase activity, protein content and protein profiles of glands from infected and uninfected beetles were compared at different days post-emergence. BAGs from infected males continued to increase in size and weight from 6-10 days post-emergence, when uninfected glands had ceased growing. Trehalase activity reflected the change in size by showing an increase in activity per whole gland. Protein profiles of infected glands remained unchanged but total protein content per gland was significantly increased.

More recent studies have been concerned with the effect of the parasite on the testes and spermatozoa of *T. molitor*. Sperm motility and oxygen consumption / CO₂ production were assessed and results will be discussed with respect to a possible enhancement of male reproductive potential.

04-049

EXPRESSION OF HUNCHBACK, KRÜPPEL AND EVEN-SKIPPED IN THE LOWER DIPTERAN *CLOGMIA ALBIPUNCTATA* WILLISTON (NEMATOCERA: PSYCHODIDAE)

K. Rohr¹, K. Sander², D. Tautz¹

¹Zoologisches Institut der Universität München, Germany;

²Zoologisches Institut der Universität Freiburg, Germany

The mothmidge *Clogmia albipunctata* is considered to be a primitive nematoceran and shows a morphological long germ development with some differences to *Drosophila melanogaster*.

As the comparison of gene expression has become an useful approach to get information about the evolution of developmental mechanisms, we searched for the segmentation gene (gap gene) orthologues hunchback and Krüppel by PCR in *Clogmia* and used the PCR products as probes for in situ hybridizations. In addition, we used an interspecifically reacting monoclonal antibody to visualize the protein expression of the segmentation gene (pair rule gene) orthologue even-skipped in *Clogmia* embryos.

The expression patterns of the segmentation gene orthologues hunchback, Krüppel and even-skipped show some differences to *Drosophila*. In the late appearance of some posterior elements of the patterns, *Clogmia* seems to have some aspects of short germ development. Differences of the posterior domains of hunchback and Krüppel expression could reflect a different mode in the generation of the most posterior segments.

In general, secondary expression is more variable than primary expression, as it is already known from other species. We suggest that the basic functions of these genes are conserved between *Drosophila* and *Clogmia*. However it is surprising that secondary expression patterns differ in such a striking way between closely related species. Most striking is the complete absence of a secondary set of even-skipped expression in *Clogmia*.

04-048

OVARIAN DEFECTS IN HYBRIDS OF THE SPECIES PAIR *DROSOPHILA VIRILIS* AND *DROSOPHILA TEXANA*
K. Lamnissou
Department of Biology, Section of Biochemistry, Molecular and Cellular Biology and Genetics, Athens, Greece

In interspecific matings between *Drosophila virilis* and *Drosophila texana* female sterility is observed in F₂ hybrid females. A previous study has shown that no vitellogenin synthesis occurs in the fat body of sterile hybrid females. The results of this work show that hybrid ovaries of sterile females transplanted into the abdomens of females of the parental species are not able to develop upon maturity. With few exceptions, the hybrid ovaries remained alive in the host environment, but their oocytes failed to develop to vitellogenic stages.

Thus, in hybrid females between *Drosophila virilis* and *Drosophila texana* sterility is the result of defects in at least two developmental processes, synthesis of vitellogenins in the fat body and uptake of vitellogenins by the developing oocytes.

04-050

ISOLATION AND CHARACTERIZATION OF A *BOMBYX VASA*-LIKE CDNA

H. Nakao, T. Iyata, S. Imanishi

Department of Insect Genetics and Breeding, National Institute of Sericultural and Entomological Science, Tukuba Ibaraki, Japan

As a first step toward the establishment of germ cell culture system in the silkworm, *Bombyx mori*, we attempted to obtain a molecular marker of the germ cell. DEAD BOX family includes many genes that are preferentially expressed in germ line of a wide range of animal species and also the family protein has many evolutionary conserved amino acid sequence motifs useful for the isolation of unknown family genes by PCR. Here, we searched for DEAD BOX family genes expressed in *Bombyx* ovary by RT-PCR using degenerate oligonucleotide primers which correspond to such motifs. We obtained five cDNA species belonging to the family. Of those, a cDNA clone showed considerable similarity in the deduced amino acid sequence to that of the *Drosophila vasa* gene product. Using this clone, a cDNA clone containing the full ORF was isolated from a *Bombyx* ovary cDNA library. The sequence of the clone revealed that a N-terminal part of the amino acid sequence contains glycine rich region. Northern analysis showed that the mRNA existed in the egg, suggesting that it functions as a maternal factor. All these characteristics are shared with *Drosophila vasa*. An antibody directed against a bacterially synthesized polypeptide of the cDNA was made and the function of the gene in the early development is now under investigation.

04-051

DEVELOPMENTAL ANALYSIS OF LEG AND GENITALIA FORMATION OF THE SILKWORM, *BOMBYX MORI*, USING GYNANDROMORPH MUTANT

T. Ohtaki, M. Kobayashi¹

Department of General Education, Nishogakusha University, Shonan, Chiba - ¹Department of Sericulture, Faculty of Agriculture, Tokyo University, Bunkyo-ku, Tokyo, Japan

In this study, a hybrid race of the silkworm, *w^{PSa}mo, p, w-2/+ , mln/+ X mo, p(or ps/p), w-2, mln*, was used. This hybrid mutant produces gynandromorph mosaic in a high rate.

In early embryological studies, it was observed that larval legs were formed as extrusion of ventral part of the integument. However, individuals with pleurite/sternite dissociation of larval body color imply that legs are produced first as an extrusion of both pleurite and sternite to lateral direction, and then move downwards, because cells of the pleurite come down to tip of the legs making a wedge shape in the sternite background.

In the median longitudinal dissociation, female and male genitalias are formed independently in one side and the other. However, in some cases, labia and ancus are produced bilaterally. These facts mean that imaginal discs of labia and ancus possibly have a potency of bilateral regeneration.

04-053

MOLECULAR CLONING AND GENOMIC ORGANISATION OF A NOVEL RECEPTOR FROM *DROSOPHILA MELANOGASTER* STRUCTURALLY RELATED TO MEMBERS OF THE GLYCOPROTEIN HORMONE (THYROID STIMULATING HORMONE, FOLLICLE STIMULATING HORMONE, LUTEINIZING HORMONE, CHORIOGONADOTROPIN) RECEPTOR FAMILY FROM MAMMALS

F. Hauser, C.J.P. Grimmelikhuijzen, Department of Cell Biology and Anatomy, University of Copenhagen, Copenhagen, Denmark.

In mammals, reproduction is controlled by: (1) steroid hormones, (2) a family of closely related glycoprotein hormones produced by the adenohypophysis (luteinizing hormone, LH; follicle stimulating hormone, FSH), or placenta (choriogonadotropin, CG), and (3) hypothalamic releasing hormones (e.g. luteinizing hormone releasing hormone, LHRH) that control the release of LH and FSH from the adenohypophysis. Several years ago, the receptors for mammalian FSH, LH and CG have been cloned, as well as the receptor for a fourth glycoprotein hormone, thyroid stimulating hormone (TSH) that is also produced by the adenohypophysis. The receptors for LH and CG appeared to be identical. All three receptors are closely related and form a subfamily belonging to the large family of G-protein-coupled (7 transmembrane) receptors. Using oligonucleotide probes derived from consensus sequences for these glycoprotein hormone receptors, we have now cloned a 831 amino acid residues long receptor from *Drosophila melanogaster* that shows a striking structural homology with the TSH, FSH, LH/CG receptor family from mammals. This homology includes a very large, extracellular N terminus (20% sequence identity with the rat TSH, FSH, LH/CG receptors) and a 7 transmembrane region (53% sequence identity with the rat receptors). The *Drosophila* receptor gene is >7,5 kb long and contains 17 exons and 16 introns. Many of the intron-exon transitions coincide with the intron-exon transitions of the mammalian glycoprotein hormone receptor genes. All this indicates that the *Drosophila* receptor is evolutionarily related to the mammalian receptors. We expect that the novel insect receptor is involved in insect reproduction or development.

04-052

LOCALIZATION OF LOCUSTATACHYKININ-I-IMMUNOREACTIVE PEPTIDES IN DEVELOPING EMBRYO OF *DROSOPHILA MELANOGASTER*

D. W. Kwon, H. O. Kang, B. H. Lee

Department of Biology, Korea University, Seoul, Korea.

Drosophila embryos were described to produce various kinds of peptides during their developmental stages. We confirmed that, in *Drosophila melanogaster*, one of them is Locustatachykinin I, which has been purified in brain and retrocerebral complex (corpus cardiacum-corpus allatum), and has been also shown to play major roles as a myotropic contraction in foregut and oviducts in *Locusta*. The locustatachykinin-I-immunoreactive (LomTK-I-IR) peptides are first seen as several stained spots in both anterior and posterior tips during developmental stages of *Drosophila* embryo. This stage is thought to be early stage of neurulation. In the mid stage of neurulation, LomTK-I-IR peptides are found mostly in medial dorsal region of posterior part of *Drosophila* embryo, as well as in anterior and posterior regions. After the neurulation, the LomTK-I-IR peptides are located as one or two large staining clumps of the embryo. Thereafter, the LomTK-I-IR peptides are strongly stained in three segments of thoracico-anteroabdominal part of the embryo. When the embryo development is nearing along toward 1st instar larval stage, the localization pattern of the LomTK-I-IR peptides differs from that localized in earlier embryo. The three large clumps of the LomTK-I-IR peptides are changed first into various small spots, and then into more large spots, especially in ventral regions of the embryos. Thus, the embryo nearer to 1st instar larva shows various large LomTK-I-IR spots in ventral portion of the embryos.

04-054

TRANSCRIPTIONAL REGULATION OF A CHORION GENE PAIR DURING OVARIAN DEVELOPMENT IN THE SILKMOTH *BOMBYX MORI*.

M.D. Lunke, J.R. Drevet, Y.A.W. Skeiky and K. Iatrou, Department of Medical Biochemistry, the University of Calgary, Calgary, AB, T2N 4N1 Canada.

The chorion of the silkworm, *Bombyx mori*, is composed of over 100 different proteins that are synthesized and secreted in a specific order during oogenesis by follicular cells surrounding the developing oocyte. Chorion protein synthesis is regulated at the transcriptional level. Chorion genes are organized in divergently oriented pairs separated by short, common promoter regions containing all the elements required for normal expression.

Research in our laboratory focuses on the establishment and implementation of the choriogenic developmental program in follicular cells. We have previously identified two proteins, BCFI and BCFII, that bind specifically to the promoter of HcA/B.12, a chorion gene pair exclusively expressed during the late stages of choriogenesis and used as a model in our studies. Although BCFI only appears in the nuclei of follicular cells at the late stages of choriogenesis, coincident with the expression of HcA/B.12, strong evidence suggests that it is actually synthesized much earlier and stored in the cytoplasm in a phosphorylated form as an inactive precursor. BCFI binds to the DNA sequence AGATAA on the HcA/B.12 promoter and is a product of the gene BmGATA β , which encodes at least 3 isoforms by alternative splicing. The 3 proteins encoded by BmGATA β belong to the GATA family of zinc finger-containing DNA-binding proteins, and differ from one another in the organization of their DNA-binding domains.

Our present aim is to determine how the three GATA proteins encoded by BmGATA β differ functionally. We are currently raising and characterizing isoform-specific antibodies that will be used to determine the abundance and subcellular localization of each protein isoform in follicular cells at different stages. The DNA-binding specificity of the three GATA proteins will be studied, and finally, their potential as transcriptional activators of the HcA/B.12 gene will be addressed using *in vitro* transcription assays.

04-055

THE SILKMOTH HOMOLOG OF THE VERTEBRATE NUCLEAR RECEPTOR HNF-4 : CLONING AND ANALYSIS OF EXPRESSION DURING FOLLICULAR DEVELOPMENT

L. Swevers, M.D. Lunke and K. Iatrou

Department of Medical Biochemistry, The University of Calgary, Calgary, Alberta T2N 4N1, Canada

A cDNA library of follicular cells from vitellogenic follicles of *Bombyx mori* was screened under low stringency conditions with a probe derived from the DNA binding domain of the ecdysone receptor for the presence of additional members of the steroid hormone receptor superfamily. The predicted amino acid sequences of seven isolated clones are identical in their DNA binding, hinge and ligand-binding domains, but could be grouped into two classes with respect to their amino-termini (activation domains). All clones share close similarity with the vertebrate orphan receptor hepatic nuclear factor-4 (HNF-4) in their DNA binding domain (88 % at the amino-acid level).

Southern blot analysis shows that the silkmouth HNF-4 homolog (BmHNF-4) is present as a single copy gene in the genome. Northern blot analysis detects two mRNA species of 4.8 and 5.2 kb that are predominantly present in follicular/nurse cells of maturing follicles. The mRNAs accumulate in the oocyte during vitellogenesis and are abundant in newly-laid eggs. The RNA expression patterns therefore suggest that the BmHNF-4 mRNAs are maternal mRNAs that play a role in early embryonic development. Upon *in vitro* expression, BmHNF-4 shows strong binding to the vertebrate HNF-4 DNA-binding site of the apolipoprotein CIII promoter. A similar binding activity could also be detected in nuclear extracts prepared from vitellogenic follicles, suggesting that BmHNF-4 also functions as a transcription factor in the nuclei of follicular cells.

04-057

EFFECT OF Ca^{++} ON THE CATHEPSIN B-LIKE PROTEINASE IN TUSSAH, *ANTHERAEA PERNYI*

Xiao-fan Zhao, Jin-xing Wang

Department of Biology, Shandong University, Jinan, China

To clarify the mechanism of the activation of the egg proteinases was significant for the controlling of pest insects. Although several kinds of egg proteinases have been studied and purified from some insects, the mechanism of the activation about the egg proteinases has not been completely clarified up to now.

The effects of the metal ions on the cathepsin B-like proteinase in *Antheraea pernyi* were studied by using the purified proteinase. The results showed Ca^{++} could increase the activity of the proteinase. The bovine serum albumin and vitellin could be well hydrolyzed by the cathepsin B-like proteinase when the Ca^{++} was existing, but not when the Ca^{++} was absent. The results suggested that Ca^{++} stimulation might be one of the mechanism of the activation in this egg proteinases.

04-056

STUDIES ON THE PROPERTIES OF THE EGG PROTEINASES IN COTTON BOLLWORM, *HELIOPERPA ARMIGERA*

Xiaofan Zhao, Jin-xing Wang

Department of Biology, Shandong University, Jinan, China

A proteolytic activity was detected in the developed oocytes of *Helicoverpa armigera*. The optimum pH for the enzyme was 3-5. The activity of the enzyme could be inhibited by N-[N-(1,3-trans-carboxyoxiran-2-carbonyl)-L-leucyl]-agmatine (E-64), pepstatin and diisopropyl fluorophosphate (iPr₂P-F). A highest hydrolysis rate was detected at pH 4 when the bovine hemoglobin was used as the substrate. The antisera to the cysteine proteinase and aspartic proteinase of *Philosamia cynthia ricini* could recognize the antigene in the oocytes of *H. armigera*. The results suggested that there were cysteine proteinase and aspartic proteinase in the oocytes of *H. armigera*, and the properties of the proteinases were similar to those in *P. C. ricini*. Moreover, the vitellin from *H. armigera* was identified and compared with that in *P. C. ricini*.

04-058

HORMONAL REGULATION OF VITELLOGENESIS IN THE SOFT TICK, *ORNITHODOROS MOUBATA* (ACARI: ARGASIDAE)

D. Taylor and Y. Chinzei¹

Department of Applied Zoology, Institute of Agriculture and Forestry, University of Tsukuba, Tsukuba, Ibaraki, Japan
¹ Department of Medical Zoology, School of Medicine, Mie University, Tsu, Mie, Japan

We determined that juvenile hormone (JH) does not regulate vitellogenin (Vg) synthesis in *Ornithodoros moubata*. Therefore, we undertook studies to determine the hormonal regulation of vitellogenesis in adult females of this species. Normal induction of vitellogenesis requires mating and engorgement. However, we were able to stimulate vitellogenesis in unfed mated females by injection with synganglion (SyG) extracts and topical application of cypermethrin. Ligation experiments revealed that Vg synthesis is regulated by two factors. First, vitellogenesis inducing factor (VIF) is released from the SyG. VIF in turn stimulates a tissue in the posterior portion to release a second factor, fat body stimulating factor (FSF), which stimulates the fat body to synthesize Vg. Experiments indicate that VIF is a peptide and FSF may be an ecdysteroid. Further studies showed that ecdysteroid titres in the hemolymph increase after feeding and injections of ecdysteroids stimulate low levels of Vg synthesis in unfed mated females.

04-059

EXPRESSION OF AUTOGENY DEPENDING ON TENERAL RESERVES IN CULEX AND ANOPHELES (DIPTERA: CULICIDAE)

S. Rintelen & H. Briegel
Zoologisches Institut der Universität Zürich, Zürich / Switzerland

Total protein and lipids present at eclosion of teneral female mosquitoes largely reflect the larval feeding history. In addition, the genotype determines the metabolic potential for biosynthetic processes, particularly of total protein and reserve lipids. Most clearly this is expressed when comparing autogenous strains of mosquitoes that are able to accumulate more reserves during their larval development with their anautogenous conspecifics. The excessive protein contents in autogenous genotypes allow the maturation of their first batch of eggs without blood meals.

Our previous studies revealed minimal amounts of total protein and lipids in teneral Anophelines when compared to Culicines. This became particularly evident when the caloric measurements were normalized for a constant body size. Based on these findings it appeared unlikely for Anophelines to evolve autogeny as a mode of reproduction. Therefore it was interesting to explore the situation in the autogenous species *Anopheles near salbaii* (kindly provided by Dr. A. Spielman). As controls we chose *An. gambiae*, an anautogenous representative of similar body size and, furthermore we reinvestigated autogeny in *Cx. pipiens*.

The autogenous *An. nr. salbaii* had twice the protein content per female at eclosion than the anautogenous *An. gambiae*, while its lipid content was even quadrupled. In *Cx. pipiens* there were similar trends but much weaker in extent (protein increased by 20%, lipid doubled). Furthermore, all these proportions showed positive correlations with body size. After oviposition, female protein and lipid contents were equal for autogenous and anautogenous phenotypes, but species-specific.

Detailed information on the kinetics of yolk deposition, its subsequent partial resorption, and the maternal investment during oogenesis will be presented and discussed for the various phenotypes studied.

Supported by the Swiss National Science Foundation.

FIRST RECORD OF GYNANDROMORPHISM FOR ANACRIDIDIUM AEGYPTIUM (L.) (ORTHOPTERA: CATANTOPIDAE)

R. Nicoli Aldini
Istituto di Entomologia e Patologia vegetale, Università Cattolica del Sacro Cuore, Piacenza, Italy

Gynandromorphism has been scarcely recorded among Orthoptera in comparison with other orders of Insects, such as Lepidoptera and Hymenoptera. As far as Ensifera are concerned, the evidence of this rare condition is more immediate, whereas it is morphologically less marked among Caelifera, according to slighter external differences between the sexes; the described gynandromorphs amount at present to a few dozens and refer to about twenty-five species for the last suborder. The study of this phenomenon involves several branches of general entomology, such as genetics, embryology, external morphology, anatomy, ethology, and it is interesting also as regards the taxon concerned. A bilateral gynandromorph of *Anacrididium aegyptium* (L.) (Orthoptera Caelifera: Catantopidae) was collected near Imperia (Northern Italy) in February 1993. Since the specimen came already dead under observation, behavioural data are not available: the external morphology, which exhibits various asymmetries, could be only considered. The size of the specimen is approximately intermediate between the mean male and female dimensions for this species. In the head the right antenna is slightly longer than the left. In the thorax a small distortion is evident in the prothorax, the right paranotum being a little longer than the left, and the metathoracic pair of legs is asymmetrical, the right leg being slightly longer. In the genital and post-genital segments of the abdomen there is lateral bipartition of the external morphological characters which are female on the right side and male on the left, as in the majority of gynandromorphs described up to now for Orthoptera. This is evident in the VIII sternite, which forms the right half of the female subgenital plate, and in the X tergite, epiproct, paraprocts, and cerci. The left half of the male IX sternite is present and prolonged in the left half of the male subgenital plate. On the right side, the two ovipositor valves are present: the dorsal valve is normal in shape, while the ventral is slightly anomalous and deviated medially. No instance of gynandromorphism results previously reported for this species.

04-060

ULTRASTRUCTURAL PROPERTIES OF THE FOLLICULAR EPITHELIUM OF THE HONEY BEE APIS MELLIFERA (L.) DURING VITELLOGENESIS

R. Fleig
Institut für Zoologie, Technische Universität, Dresden, Germany

During previtellogenesis the follicular epithelium is tightly closed when the cells are connected with each other laterally by continuous *Zonulae adherentes*. During vitellogenesis the follicle cells show a hexagonal pattern in horizontally orientated sections. The *Zonulae adherentes* are still present almost all around each cell, but tiny, pore-like intercellular canals appear in the corners where always three cells meet. These canals connect the intercellular space basally of the follicle cells with the perivitelline space between follicular epithelium and oocyte. In the medial part of each canal a F-actin bundle is found closely inside each of the three participating cells stretching horizontally from one cell wall to the other. Together these three bundles form a ring around the canal. From these rings F-actin bundles stretch horizontally along the tight connected lateral cell membranes. Apically the follicle cells extrude long, finger-like protuberances through the narrow perivitelline space and deep into the oocyte. They are densely filled with longitudinally arranged F-actin bundles. The lumen of the canals apically of the F-actin rings and the perivitelline space are filled with an electron dense substance which contains vitellogenin; basally of the rings the lumen of the canals and the intercellular space are devoid of this substance. Canals, protuberances, and their F-actin elements may be involved to direct the vitellogenin towards the surface of the oocyte where it is taken up by endocytosis.

04-062

THE INFLUENCE OF FEEDING AMOUNT ON THE DEVELOPMENT DURATION OF MYRMELEON (MORTER) SAGAX LARVA

Zhou Hanhui, Zhang Xuanda
Research Institute of Entomology, Zhongshan University, Guangzhou 510275 China

Myrmeleon sagax (Neuroptera: Myrmeleonidae) is one generations a year in nature condition. In laboratory condition, however, the feeding amount of larva can affect its development. Three generations in one year were observed in our experiment by providing sufficient food; one complete generation was observed from June to August, under the long photostage and high temperature conditions. It was found that the third instar larva differentiate after autumn by feed once in a interval of 15 days, a few larva can complete its development into adult after few months, and most of larva delay its development to next year.
Key words: ant-lion *Myrmeleon sagax*

POLYDNAVIRUSES AND PARASITOID HOST RANGE: AN IMMUNOLOGICAL VIEWPOINT

D. Trudeau and M.R. Strand

Department of Entomology, University of Wisconsin-Madison, Madison, WI USA

Endoparasitic wasps of the families Braconidae and Ichneumonidae have developed a unique strategy to protect their developing progeny from the action of their host's immune system. The female wasps of these two families carry within their ovaries a virus which belongs to the family Polydnviridae. Typically, these viruses are injected along with the wasp's egg directly into the hemocoel of a larval host. Polydnviruses then, either alone or in concert with other wasp derived factors, induce profound changes in the cellular and humoral immune system of the parasitized host. The extent to which polydnviruses determine their parasitoid's host range is not known. We chose to use *Microplitis demolitor* and its associated virus, *Microplitis demolitor* polydnvirus (MdPDV) to address this question since previous work has shown that, in this particular system, persistence and expression of the polydnvirus is sufficient and necessary to cause immune disruption. Investigation of wasp progeny survival, immune function, viral persistence and expression was carried out using *Microplitis demolitor*, and three lepidopteran species as wasp hosts. These included *Pseudoplusia includens*, *Spodoptera frugiperda* and *Trichoplusia ni*. Preliminary studies indicated that these noctuid species varied in their permissiveness as wasp host. Results obtained to date suggest that persistence of polydnvirus expression is one of the key factors in determining whether or not a particular lepidopteran species is a suitable host for the wasp and support the hypothesis that polydnviruses act as true host range determinant.

05-001

DEVELOPMENTAL PROFILE AND CYTOPATHIC EFFECTS OF AN ENTOMOPOXVIRUS FROM A PARASITIC WASP

Pauline O. Lawrence, Department of Entomology and Nematology, University of Florida, Gainesville Florida, USA.

Entomopoxvirus (DIEPV) particles from the venom apparatus (accessory gland) of the parasitic wasp *Diachasmimorpha (Bioesteres) longicaudata*, are introduced into Caribbean fruit fly (*Anastrepha suspensa*) larvae by ovipositing wasps. Mouse polyclonal antibodies generated against sucrose density gradient purified DIEPV detected viral proteins in Western blots of host hemocytes and to a lesser extent of host fat body <24 h post-parasitization. The intensity of the viral protein signal from host cells increased significantly by 36 h post-parasitization, coincident with the onset of the parasite's first larval stadium. Southern hybridization using digoxigenin-labeled DIEPV DNA as a probe, confirmed the presence of the virus within the hemocytes. Immunofluorescent labeling of host hemocytes using the anti-DIEPV protein serum and an FITC-labeled second antibody, localized viral proteins in hemocyte cytoplasm. The affinity of selected FITC-labeled lectins to virus-infected hemocytes was different from that observed for healthy hemocytes. Furthermore, DIEPV infection altered f-actin arrangement in infected hemocytes.

05-003

CYSTEINE-RICH PROTEIN FROM *CAMPOLETIS SONORENSIS* AND ITS ASSOCIATED POLYDNAVIRUS.

B.A. Webb, L. Cui and A. I. Soldevila, Department of Entomology, University of Kentucky, Lexington KY, U.S.A.

Parasitoids employ polydnviruses, venoms and ovarian proteins to inhibit the immune system of their hosts during endoparasite development. In the *Campoletis sonorensis*-*Heliothis virescens* system, ovarian proteins acutely suppress the immune system at early times after parasitization while proteins expressed from the polydnvirus are required for chronic suppression. An ovarian protein with multiple glycoforms that is encoded by a single copy *C. sonorensis* gene and a family of cysteine-rich polydnvirus proteins appear to suppress the insect cellular immune response. Our studies have focused on the *C. sonorensis* polydnvirus VHv1.1 and VHv1.4 genes both of which are glycosylated and contain 2 copies of a motif with 6 cysteine residues each. The ovarian protein also is glycosylated and cysteine-rich (~3% cysteine). Although cysteine residues in the ovarian protein are clustered they do not comprise a motif similar to the polydnvirus motifs. We have begun a series of experiments to determine the functionally important regions of the parasitoid immunosuppressive proteins. These proteins bind and localize to hemocytes with internalization blocked by incubation at 4° C suggesting that this is an active process involving endocytosis of receptor protein complexes from the hemocyte surface. Cysteine residues are involved in disulfide formation for intramolecular linkage and confer structural stability necessary for biological activity. Treatment of cys-proteins with reducing agents which disrupt disulfide bridges within proteins, inhibits the binding of these proteins to hemocytes. As dithiothreitol concentrations increase, the binding of the proteins to hemocytes is significantly reduced. These genes have been expressed in the baculovirus system and linked to a poly-histidine tract allowing purification of individual proteins for functional analyses. As an initial step towards determination of the 3-dimensional structure the pattern of linkages within the cysteine motifs is being mapped. The importance of the carbohydrate residues as related to biological activity is also being evaluated by endoglycosidase-H digestion and by site-directed mutagenesis to remove or prevent glycosylation. Differences and similarities of the ovarian and polydnvirus proteins in terms of their expression, tissue-specific binding and effects on the *Heliothis virescens* immune system will be discussed.

05-004

IMMUNITY INTERACTIONS BETWEEN THE BRACONID *ASOBARA TABIDA* AND *DROSOPHILA* LARVAL HOSTS

P. Eslin, P. Giordanengo, G. Prévost

Biologie des Entomophages, U.P.J.V., 33 rue Saint Leu, Amiens, France.

Avoidance of encapsulation by *Asobara tabida* (Hym.; Braconidae) in *Drosophila* larval hosts is the result of a physiological race between the host's ability to quickly form a hemocyte capsule and the aptitude of the parasitoid to get protected from the attack by the hemocytes. *Drosophila* ability to encapsulate *A. tabida* is associated with high number of circulating hemocytes. This association is verified among several *Drosophila* species of the subgroup *melanogaster*.

Avoidance of encapsulation by *A. tabida* is associated with a quick embedment of the parasitic egg within the host tissues. Recognition of the parasite by the host cells thus must be affected in such manner that host tissues (digestive tube, fat body, muscles and trachea) are strongly sticking to the parasite's egg chorion while the host hemocytes are not attaching to it.

No VLP were found in the accessory glands of the parasite. Factors responsible for the inhibition of encapsulation are investigated at both physiological and molecular levels.

05-006

MANIPULATION OF HOST (*SPODOPTERA LITTORALIS*) DEVELOPMENT AND ENDOCRINOLOGY BY THE PARASITOID *CHELONUS INANITUS*: EFFECTS OF POLYDNAVIRUS/VENOM AND OF THE PARASITOID LARVA

B. Lanzrein¹, R. Pfister-Wilhelm¹, C. Grossniklaus-Bürgin¹, M. Soller¹, B. Steiner¹, K. Treiblmayr²

¹ Division of Developmental Biology, Institute of Zoology, University of Berne, Berne, Switzerland - ² Institute of Zoology, University of Salzburg, Salzburg, Austria

Parasitization by the egg-larval parasitoid *Chelonus inanitus* strongly influences later stages of host development. Non-parasitized larvae pass through 6 larval instars, but parasitized larvae enter metamorphosis in the 5th instar. The parasitoid larva then emerges from the precocious prepupa and feeds on it. If the parasitoid fails to emerge, the host never pupates but remains developmentally arrested in the prepupal stage. We could show that polydnavirus/venom are responsible for induction of developmental arrest in the prepupa while the parasitoid larva plays a key role in inducing precocious onset of metamorphosis. We made comparative measurements of juvenile hormone (JH) biosynthesis in vitro, JH titres, ecdysteroids titres and juvenile hormone esterases in non-parasitized, parasitized or polydnavirus/venom containing larvae. Our data indicate that the presence of a late 1st instar parasitoid larva reduces JH biosynthesis by host c. allata and JH titers; this then induces the subsequent premetamorphic changes in JH esterase and ecdysteroids. In polydnavirus/venom containing larvae endocrine differences to non-parasitized larva become manifest only in the 6th instar, the main difference being modified JH esterase and ecdysteroid patterns.

05-005

LIFE CYCLE AND FUNCTIONS OF THE POLYDNAVIRUS OF THE BRACONID WASP *CHELONUS INANITUS*

P. Stettler, A. Gruber, M. Soller, R. Pfister-Wilhelm, B. Lanzrein

Division of Developmental Biology, Institute of Zoology, University of Berne, Berne, Switzerland

The calyx cells of the ovary of *C. inanitus* contain large numbers of polydnaviruses (PDV) (Albrecht et al., 1994, J. Gen. Virol. 75, 3353-3363). We could show that viral DNA is integrated into wasp genomic DNA and excised and circularized only in females (A. Gruber, this meeting). At oviposition PDV are injected along with venom and the parasitoid egg into the host egg. On the basis of Southern blot analyses we show that viral DNA persists in the course of host larval development in several tissues.

Furthermore data on transcription of viral DNA will be presented. PDV are indispensable for parasitoid development as they suppress the immune reaction of the host against the parasitoid larva. Comparative analyses of morphology, spreading behaviour and relative abundance of the various types of haemocytes revealed no major differences between non-parasitized and PDV/venom containing larvae. Also, encapsulation experiments indicated that PDV/venom do not generally suppress the immune system of the host but specifically prevent encapsulation of the parasitoid larva. Another function of PDV/venom in this egg-larval parasitoid is induction of a developmental arrest in the prepupal stage, a phenomena also observed in several larval parasitoids.

DEVELOPMENTAL AND PHYSIOLOGICAL EFFECTS ON HOSTS INDUCED BY CHELONINE WASPS

Davy Jones

Graduate Center for Toxicology, Chandler Medical Center, University of Kentucky, Lexington, KY 40506-0305; DJONES@POP.UKY.EDU

Parasites in the subfamily Cheloninae cause several developmental and physiological changes in their hosts, and impart a number of regulatory agents to the host to cause these effects. These effects include precocious initiation of metamorphosis, suppression of prepupal development, host castration and suppression of the host immune response. These effects are seen both in hosts containing a live endoparasite larva ("truly parasitized") as well as in hosts containing no live endoparasite ("pseudoparasitized"). A number of laboratories have addressed the source of these effects in species of *Chelonus*, *Phanerotoma* and *Ascogaster*. While it is possible to cast the various results in a manner that creates the appearance of a particular contradiction, such impasses may be more apparent than real, and where possible it is more informative to discern a harmonious explanation that sheds light on what effects are actually happening. In one effect to be discussed, high ecdysteroid measurements on truly parasitized prepupae may appear not to support measurements of low ecdysteroid titers in pseudoparasitized prepupae. However, these results were seen to be harmonious when it was determined that what is actually happening is that the parasite larva secretes ecdysteroids into the hemolymph of the host, whose endogenous ecdysteroid titer has been suppressed. Application of this methodology to the experimental results reported from various chelonine-host systems productively generates an embrative model for the underlying biochemical and physiological interactions.

05-008

SELECTIVE ACTION OF TERATOCYTE SECRETORY PRODUCTS ON HOST AND NON-HOST TISSUES.

D.L. Dahlman, D. Zhang, E.J. Schepers and F.A. DiLuna

Dept. of Entomology, University of Kentucky, Lexington, KY USA

In the host parasitoid association *Heliothis virescens* (F.) - *Microplitis croceipes* (Cresson), teratocytes play a role that is apparently independent of the parasitoid larva and accompanying polydnavirus and venom injected into the host at the time of oviposition. The most obvious effects are inhibition of larval growth and pupation. The hemolymph from both parasitized larvae and larvae injected with physiological doses of teratocytes have depressed levels of juvenile hormone esterase (JHE) and arylphorin, although their respective mRNAs are reduced only in parasitized larvae. The reduction of arylphorin mRNA level is tissue-specific because no reduction was observed in testes from the same parasitized larvae. Our data suggests that teratocytes may negatively regulate a post-transcriptional mechanism. Teratocyte secretory products (TSP), obtained from *in vitro* cultures of teratocytes, inhibit the *in vitro* production of JHE by fat body in a dose dependent manner. In addition, TSP inhibits the incorporation of [³⁵S]-methionine into proteins when used in *in vitro* tissue assays of both fat body and larval testes. With respect to transcriptional and post-transcriptional events, we know that the responses of parasitized larvae and larvae injected with teratocytes are different. We examined the effects of TSP on the ability of fat body, testes, salivary gland, midgut and epidermal tissues from *H. virescens* and *Helicoverpa zea* (Boddie) (permissive hosts for *M. croceipes*) and *Manduca sexta* (L.) (nonpermissive host) to synthesize protein. Similar tissues from parasitized and nonparasitized *H. virescens* larvae were compared. Some tissue types from permissive hosts were more sensitive to TSP while the nonpermissive host tissues showed little response. Tissue response also depended upon the developmental age of the tissue. Fat body and testes were the most sensitive tissues. TSP effects on JHE synthesis by fat body of the three species was also measured.

05-010

PROTHORACIC GLAND INACTIVATION IN *HELIOTHIS VIRESCENS* (F.) (LEPIDOPTERA, NOCTUIDAE) LARVAE PARASITIZED BY *CARDIOCHILES NIGRICEPS* VIERECK (HYMENOPTERA, BRACONIDAE)F. Pennacchio, P. Falabella, R. Sordetti, C. Malva¹, S. B. Vinson²
Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy - ¹Istituto Internazionale di Genetica e Biofisica, CNR, Napoli, Italy - ²Department of Entomology, Texas A&M University, College Station, TX, U.S.A.

Heliothis virescens (F.) larvae parasitized by the endophagous braconid *Cardiochiles nigriceps* Viereck become developmentally arrested as last instars and fail to pupate. The biosynthetic activity of prothoracic glands of mature larvae parasitized, or treated with *C. nigriceps* calyx fluid and venom, is severely depressed, even though their histological degeneration is not observed and only minor ultrastructural changes are evident. This functional block is due to an alteration of the signal transduction pathway under PTTH control. The increased endocellular level of cAMP, induced by PTTH stimulation, fails to activate the cAMP dependent protein kinase, resulting in a marked underphosphorylation of target proteins. This is associated to a translational block of protein synthesis, which is a fundamental step of steroidogenic responses in animals. Time-course studies demonstrated that this alteration can be observed within 12 hr from parasitoid oviposition into host last instar larvae. Southern blot experiments indicate the presence of a PKI (protein kinase inhibitor)-like gene in *C. nigriceps*. PKIs so far isolated and characterized have a pseudosubstrate structural domain, which could inactivate a protein kinase by folding back into the active site. Further studies are in progress to characterize this parasitoid gene and to assess if it could be involved in prothoracic gland inactivation of parasitized *H. virescens* last instar larvae.

05-009

REGULATION OF HOST (*MANDUCA SEXTA*) HEMOLYMPH ECDYSTEROID LEVELS BY THE PARASITIC WASP, *COTESIA CONGREGATA* (LEPIDOPTERA: SPHINGIDAE - HYMENOPTERA: BRACONIDAE)D. B. Gelman, T. J. Kelly, D. A. Reed¹, N. E. Beckage¹INHL, ARS, USDA, Beltsville, MD, USA, and ¹Department of Entomology, University of California, Riverside, CA, USA

When parasitized, last-instar *Manduca sexta* larvae undergo developmental arrest. Neither a premolt hemolymph ecdysteroid peak nor a pupal molt is observed. A small peak of ecdysteroid is present in host hemolymph 12 to 24 hours prior to parasite emergence and the parasite's concurrent molt to the third instar. Ecdysteroids present in this host peak were 20-hydroxyecdysone, 20,26-dihydroxyecdysone, one or more very polar ecdysteroids, and small quantities of 26-hydroxyecdysone and ecdysone. Ligation experiments suggested that the parasite is partially responsible for the observed ecdysteroid peak. To clarify the mechanism by which the parasite controls ecdysteroid levels in the host, a larval *in vitro* prothoracic gland assay was developed to compare levels of prothoracicotropic hormone in brain extracts prepared from parasitized and unparasitized 5th instars. For unparasitized larvae (wandering +2 days) and host larvae (7 days = emergence of parasites +3 days), activity per brain was similar. However, there was a significant difference in the ability of prothoracic glands (cultured *in vitro*) from young 5th instar parasitized and unparasitized larvae to respond to brain extract; those from parasitized larvae exhibited little response. (Supported in part by NRI 92-37302-7470 to N. B.)

05-011

MECHANISM OF PARASITISM-INDUCED ELEVATION OF HAEMOLYMPH GROWTH-BLOCKING PEPTIDE LEVELS IN HOST INSECT LARVAE.

Y. Hayakawa, A. Ohnishi, Y. ENDO¹Institute of Low Temperature Science, Hokkaido University, Sapporo 060, Japan -¹Department of Applied Biology, Kyoto Institute of Technology, Kyoto 606, Japan

Parasitism of *Pseudaletia separata* larvae by the parasitoid wasp *Cotesia kariyai* causes a delay in pupation of the host last instar larvae. Previous studies revealed that parasitism elevates the level of a biogenic peptide, growth-blocking peptide (GBP), in haemolymph of the host larvae which disturbs the normal development of the last instar larvae through repression of plasma JH esterase activity, and consequently delays in pupation. Recently we demonstrated that GBP mRNA is constantly expressed in both parasitized and nonparasitized last instar larvae and there is no difference in the levels of the mRNA between both larvae, thus indicating that parasitism may not effect on transcriptional level to elevate haemolymph GBP concentration. The present study was conducted to reveal the detailed mechanism by which parasitism elevates haemolymph GBP level.

05-012

PARASITISM-INDUCED HOST PHYSIOLOGICAL SABOTAGE IN *MANDUCA SEXTA*: AN INTIMATE LOOK AT HOW PARASITOIDS KILL HOSTS

N.E. Beckage, Department of Entomology, 5419 Boyce Hall, University of California-Riverside, Riverside, CA USA 92521; nbeckage@ucr.ac1.ucr.edu or nancy.beckage@ucr.edu

The braconid wasp parasitoid *Cotesia congregata* and its associated polydnavirus impact the host's physiology via multiple mechanisms. The PDV has an immediate 'knock-out' effect on the host's immune system, causing apoptosis of the hemocytes which would otherwise avidly encapsulate the wasp eggs. The PDV-encoded 'early protein 1' is linked to successful development of the parasitoids; recent evidence suggests that EPI-like sequences are also present in other parasitoids. Later, the parasitoids evade encapsulation via non-virally mediated mechanisms. The PDV also induces host developmental arrest, which is elicited by neuroendocrine and endocrine disruption, but the virus does not appear necessary to trigger cessation of host food consumption preparatory to wasp emergence. Surrogate hosts implanted with parasitoids also cease feeding prior to their emergence. The host's respiratory physiology is altered in that the pattern of ventilation becomes transiently discontinuous as the wasps are emerging from their host, and at other times the rate of carbon dioxide emission is extremely low, providing evidence for a low metabolic rate during the final stages of parasitism. In its last instar, the host's mass is directly proportional to the number of parasites developing within it, arguing that there is a wasp 'dose-dependent' effect on host growth. The presence of the parasitoids is required for induction of testicular atrophy, which occurs in the host's final instar prior to emergence of the wasps; instead of proliferating as normal, the testes diminish in volume. Both the virus and the parasitoids cause changes culminating in host death.

05-014

REGULATION OF TESTIS GROWTH OF THE HOST, *PSEUDALETIA SEPARATA* BY THE POLYDNAVIRUS AND VENOM OF *COTESIA KARIYAI*.

T. Tanaka, E. Tagashira

Applied Entomology, School of Agricultural Sciences, Nagoya University, Chikusa Nagoya, 464-01 Japan.

The larval endoparasitoid must struggle for the resource against the host. If a part of host resource is deprived of the host by itself, its resource can not be available for the parasitoid. The male lepidopteran host develops the testis during the larval stage. If a parasitoid gives the host development leave, the parasitoid loses a part of the resource. The parasitoid, *Cotesia kariyai* suppressed the development of the host testis through polydnavirus plus venom. Its degree of suppression was dose-dependent response of the polydnavirus plus venom. The expression of polydnavirus mRNA had a peak in 12 hrs after parasitization. It was shown by the paraffin sections and the cell sorting results that the polydnavirus may arrest the meiosis and/or mitosis on the cell cycle during the developing testis of the host.

05-013

ABERRANT NUTRITIONAL REGULATION OF *DE NOVO* CARBOHYDRATE SYNTHESIS IN PARASITIZED *MANDUCA SEXTA* L.

S.N. Thompson

University of California, Riverside, USA

De novo glucose/trehalose synthesis via gluconeogenesis from amino acids by *Manduca sexta* is dependent on nutritional status. Gluconeogenesis from (3-¹³C)alanine is only induced in normal 5th instar larvae in the absence of dietary carbohydrate, while glucogenesis in insects maintained on a high carbohydrate diet can be accounted for by metabolism of alanine through the tricarboxylic acid cycle. The present studies demonstrated that this nutritional regulation is upset in *M. sexta* parasitized by *Cotesia congregata*. In parasitized larvae significant gluconeogenesis from labeled (3-¹³C)alanine and (2-¹³C)pyruvate was evident in larvae maintained on either a high or low carbohydrate diet. The TCA cycle contribution to glucogenesis in parasitized insects on the high carbohydrate diet was approximately 50%. On the low carbohydrate diet the contribution of the TCA cycle to trehalose labeling was negligible. Pentose cycling was observed in larvae on either diet, but parasitism had no significant effect, even on the high carbohydrate diet. Based on the asymmetric ¹³C distribution in trehalose the cycling rate was approximately 50% in larvae on the high carbohydrate diet and 10% in larvae on the low carbohydrate diet. The possible bases for this metabolic alteration and its potential significance are discussed.

05-015

THE PHYSIOLOGICAL CHARACTERISTICS OF THE VENOM OF THE EULOPHID PARASITOID *EUPLECTRUS COMSTOCKII*: A CHRONICLE OF VENOM PROTEINS, VENOM ACTIVITY AND STORAGE PROTEIN TITER WITHIN THE HEMOLYMPH OF *TRICHOPLUSIA NI*.

M. Knop Wright, T. Coudron¹, and S. Brandt¹

Department of Entomology, University of Missouri, Columbia, MO USA - ¹ USDA-ARS Biological Control of Insects Research Laboratory, Columbia, MO USA

The ectoparasitoid *Euplectrus comstockii* (Hymenoptera: Eulophidae) injects a venom into the hemocoel of its hosts where the hemolymph is believed to facilitate the transport of the venom to target tissues. The wasp's venom alters the physiology of the host to accommodate its young by arresting larval-larval ecdysis and stimulating the premature production of storage proteins. To further determine whether these effects are due to one or more substances within the venom, the temporal dynamics of venom activity within the hemolymph of the host was investigated by bioassaying parasitized hemolymph at different times post-parasitism for arrestment activity, and for determining storage protein production. Crude venom, extracted from *Euplectrus* venom glands, was also incubated in hemolymph or phosphate buffer outside the host, and bioassayed as well. These studies show that arrestment activity within the hemolymph decreases to < 5% within 12 hours post parasitism, while purified venom incubated in a phosphate buffer solution retains 100% of its arrestment activity over this time period. A profile of venom proteins present in parasitized hemolymph which arrests molting or stimulates storage protein production was compared to the venom profile from inactive hemolymph. These results provide further clues as to the function of specific proteins within the venom of *Euplectrus comstockii*.

05-016

HOST CASTRATION, DIAPAUSE, AND ECDYSTEROIDS; NATURAL SELECTION REFINES THE HOST/PARASITOID INTERACTION.

John J. Brown

Department of Entomology, Washington State U., Pullman, WA USA

My narrative explores a possible sequence of intermediate rewards to the castrator. These include:

1) the diversion of energy reserves away from host reproductive tissue for the benefit of the parasitoid larva. 2) The elimination of host testes that are involved with ecdysteroid metabolism, which could impair a parasitoid larva's ability to monitor the host's endocrine system in order to synchronize its own overwintering survival and vernal development with that of its host. 3) Host testes may interfere with the parasitoid's pre-egression control of apolysis of the host's integument, thereby impeding the ability of the newly molted third stadium parasitoid to egress from the host's hemocoel. These intermediate steps may have culminated in the ultimate reward for the species, *i.e.* the deterrence of host resistance to the parasitoid. The ability to castrate hosts is the result of group selection, but is probably the end product of multiple steps. As a parasitoid species masters each of the three individual evolutionary strategies mentioned above, it would have more offspring than a competitor species which has not mastered its niche.

05-018

A POSSIBLE MECHANISM FOR THE PHYSIOLOGICAL SUPPRESSION OF CONSPECIFIC AND HETEROSPECIFIC EGGS FOLLOWING SUPERPARASITISM OR MULTIPARASITISM BY COMPETING ENDOPARASITIDS

E. M. Hegazi¹ and S. B. Vinson²

¹Faculty of Agriculture, Alexandria University, El Shalby, Egypt; ²Dept. of Entomology, Texas A&M University, College Station, TX 77843, USA

The progeny of endo-parasitoids that oviposit in already parasitized hosts often fail to hatch. This occurs regardless of whether the host was parasitized sometime earlier by a conspecific or heterospecific female. Although in many cases one of the parasitoids hatch and physically attack and kill the embryo in the egg before it can hatch, in other cases there is no evidence of any physical damage. In these later cases the death of the egg has been attributed to the release of toxins by the older developing parasitoid, anoxia due to the presumed more efficient absorption of oxygen by the older parasitoid, or the absorption of essential nutrients by the older parasitoid required by the developing egg. We provide some evidence for an alternative hypothesis concerning the physiological suppression of younger eggs developing in super- or multi-parasitized hosts.

05-017

PHYSIOLOGICAL INTERACTIONS BETWEEN *GLYPTAPANTELES LIPARIDIS* (HYMENOPTERA: BRACONIDAE) AND ITS HOST LARVA, *LYMANTRIA DISPAR* (LEPIDOPTERA: LYMANTRIIDAE)

A. Schopf, C. Nussbaumer

Institut für Forstentomologie, Forstpathologie und Forstschutz, BOKU Wien, Austria

The influence of parasitism by the gregarious braconid, *Glyptapanteles liparidis*, on development, nutrition, and the juvenile hormone (JH) titer of its host larva, *Lymantria dispar*, was studied in two different host types, which were characterized by the stage of parasitization: A-hosts were parasitized during premolt into the 2nd instar, B-hosts during premolt into the 3rd instar. In the normal pattern the developmental of parasitoid larvae is extended over three host instars. The relatively constant time required by *G. liparidis* for its endoparasitic development causes varying nutritional conditions for the host-parasitoid complex, depending on the relationship between the host's size and the volume of the parasitoid complex inside the host. Thus, only early parasitized hosts showed increased rates of consumption and growth during the 3rd, penulti-mate host instar and a prolonged development during their final 4th instar. The approximate digestibility (AD-value) and conversion efficiency of ingested and digested food (ECI- and ECD-values) was uninfluenced by parasitism.

The hemolymph trehalose level the host larva was markedly reduced, when the parasitoid larvae had reached their second instar. Compared to unparasitized larvae, a markedly lower glycogen content was only found in newly molted third instar A-hosts. Final fifth midinstar B-hosts even showed a significantly higher mean glycogen level than unparasitized larvae.

Simultaneously to the reduction of the trehalose level, the JH titer increased in host larvae, when the parasitoid larvae had molt into the 2nd instar. This was especially obvious in A-hosts during the late endoparasitic period, when the JH III titer rose to values of 200-500 pmol/ml while it remained below 1 pmol/ml in unparasitized larvae. Parallel to this increase a smaller one could also be observed in the JH II titer, which is the predominant JH homologue in unparasitized gypsy moth larvae. Compared to unparasitized larvae, a generally reduced activity of JH esterase (JHE) is found in parasitized larvae throughout the pen-ultimate and final larval stages, which may be in part responsible for the increased JH II and JH III titers.

05-019

PROTON POWER AND ANIMAL PLASMA MEMBRANES

W.R. Harvey and Helmut Wiczorek¹

Dept. of Biology, Temple University, Philadelphia, USA -

¹Zoologisches Institut der Universität, München, Germany

Proton-motive forces energize animal plasma membranes throughout the animal kingdom. Six examples will be discussed - insect midgut alkalization, vertebrate kidney acidification, mammalian epididymal acidification, mammalian phagocytosis, mammalian bone resorption, and frog skin Na⁺ uptake. The electrogenic H⁺ V-ATPase consists of several subunits arranged in a peripheral V₁ domain, including a stalk that connects it with a membrane bound V₀ domain. In midgut the H⁺ V-ATPase energizes amino acid uptake and, in cooperation with an electrophoretic K⁺/H⁺ antiporter, alkalizes the lumen. In kidney ATPases are recruited to the apical membrane during acidosis and several mechanisms for regulating their activity are known. In epididymis, the enzyme produces an acid environment that is responsible for male fertility. In phagocytes the enzyme energizes microbicidal and tumoricidal activity. In bone the enzyme secretes acid which resorbs Ca²⁺ and which activates enzymes that break down the organic matrix. In frog skin the enzyme energizes Na⁺ uptake from ponds. In the same sense that energization of basolateral membranes is widely held to use Na⁺/K⁺ P-ATPases, energization of many apical membranes appears to use H⁺ V-ATPases.

05-020

CHARACTERIZATION AND LOCALIZATION OF V-ATPASE SUBUNITS IN THE TOBACCO BUDWORM AND IN MOSQUITOES

P. V. Pietrantonio¹, P. Smethurst, P. Chu, L. S. Ross, S. S. Gill,
Department of Entomology, University of California, Riverside,
CA, USA, ¹Department of Entomology, Texas A&M University,
College Station, TX, USA.

The transmembrane sector of V-ATPases is involved in proton conduction across the membrane where a 15-17 kDa proteolipid forms a putative proton channel. We previously reported the cloning of a 17kDa protein from *Heliothis virescens* which is highly homologous to the published sequences of other 17kDa proteins. An affinity-purified rabbit polyclonal antibody was developed to an antigenic and putatively extracellular region of a cloned 17 kDa proteolipid. In larval tissue sections this antibody labeled the midgut goblet cell apical membrane in *H. virescens* and the apical membrane in Malpighian tubules from *H. virescens* and *Manduca sexta*. The antibody also recognized the 17 kDa protein in an immunoblot of *H. virescens* Malpighian tubule homogenate. Immunolocalization of this protein in the midgut during the L₄-L₅ larval molt and early post ecdysis into the fifth instar in *H. virescens* indicates that the spatial expression of the 16kDa protein is developmentally regulated. Northern blot analysis revealed the presence of two transcript sizes in the midgut and Malpighian tubules. Our results strongly support the hypothesis that the 17 kDa protein is a component of the V-ATPase, where it is thought to be the proton-conducting subunit.

V-type ATPase subunits have also been cloned from the Malpighian tubules of mosquito larvae. Two of the subunits cloned show high homology to the subunits previously cloned from other lepidopteran insects.

05-022

MOLECULAR PHYSIOLOGY OF V-ATPASE FUNCTIONINGS IN THE SILK GLAND CELL OF *BOMBYX MORI*

Masaaki Azuma

Laboratory of Insect Biochemistry, Faculty of Agriculture,
Tottori University, Koyama 4-101, Tottori, JAPAN

An active transport system of vacuolar-type H⁺-ATPase (V-ATPase) was identified and characterized in the anterior silk gland of 5th instar silkworm larva, *Bombyx mori*. Using fluorescent acridine orange, acidic granules were found in the apical region of cytoplasm. The acidification of these granules was completely inhibited under the presence of 0.1-1 μ M bafilomycin A1, reversibly. This was observed throughout the larval stage of 5th instar until the onset of spinning. During the incubation with acridine orange, acidic granules seemed to be transported apically and to be concentrated beneath the apical plasma membrane. This implies that V-ATPase is shuttled between an intracellular vesicular compartment and the plasma membrane. The microsomal membrane vesicles from the anterior silk gland cell showed ATP-dependent H⁺-transport activity, which was greatly enhanced by the presence of Cl⁻. The immunological blotting test with the antibody against V-ATPase holoenzyme of *Manduca sexta* midgut showed the presence of subunit A, B, C and G of V-ATPase in the anterior silk gland cell. Molecular cloning has been done on the subunit G (13-kDa). The coding region of the cDNA showed almost identical amino acid sequences with *Manduca* midgut subunit G. Molecular genetic studies are in progress using this clone. The cellular function of V-ATPase in this tissue will be discussed, but several lines of evidences suggest that the V-ATPase of the anterior silk gland might participate in the acidification of the glandular lumen during the feeding period of 5th instar.

05-021

POSTTRANSCRIPTIONAL REGULATION OF THE INSECT V-ATPASE

H. Merzendorfer¹, R. Gräf^{1,2}, W.R. Harvey² and H. Wiczorek¹

From the ¹Zoological Institute, University of Munich, Germany and the
²Department of Biology, Temple University, Philadelphia, USA

The plasma membrane V-ATPase in the midgut of *Manduca sexta* is a multisubunit enzyme comprised of a peripheral, catalytic V₁ and a membrane bound, proton translocating V₀ complex. It is located in the apical membranes of goblet cells, where it energizes K⁺ secretion by driving electrophoretic K⁺/2H⁺ antiport. During moult, V-ATPase activity is regulated by dissociation of V₁ subunits from the V₀ complex (Sumner et. al. (1994) J. Biol. Chem. 270, 5649-5653).

We have purified and characterized a soluble V₁ complex from the cytosol of midgut cells. It is a major cytosolic protein and exhibits Ca²⁺, but no Mg²⁺ dependent ATPase activity. 25 % methanol restored Mg²⁺ dependent ATPase activity. The cytosolic complex consisted of five polypeptides, the subunits A, B, E, F and the novel 13-kDa subunit G. During moult, the amount of cytosolic V₁ complex increased twofold as compared to the amount found in intermoult larvae. Starvation of intermoult larvae led to the same amount of the cytosolic complex as during the moult, indicating similar regulatory mechanisms.

In contrast to the peripheral V₁ complex only little is known about the membrane bound V₀ domain. In a first attempt we have focussed on the membrane associated 39-kDa subunit a. Screening of a midgut cDNA library revealed several clones, two of which were partially sequenced. One clone represented the cDNA encoding subunit a, with a derived amino acid sequence exhibiting 81% identity to the corresponding bovine and human cDNAs. The second clone represented a polyadenylated antisense transcript for subunit a. Northern blots showed three transcripts for the sense (1.5, 1.8 and 2.2 kb), but none for the antisense strand. However, the presence of antisense mRNA could be detected by RT-PCR. This result might reflect antisense regulation for subunit a expression. Since this subunit may contribute to the link between V₁ and V₀ domain, its posttranscriptional regulation could also influence the assembly of the holoenzyme.

A GENETIC MAP OF THE *DROSOPHILA MELANOGASTER* MALPIGHIAN TUBULE

J.A.T. Dow, M.A. Sozen, D.C. Kelly, K. Kaiser

Division of Molecular Genetics, Institute of Biomedical and Life Sciences,
University of Glasgow, Glasgow G12 8QQ, U.K.

Physiology tends to be analytical; that is, the problem is simplified in order to make it tractable. Frequently, this leads to a progression from whole animal to cell culture, either of cells from the tissue in question and expressing at least some differentiated property of interest; or of a cloned gene expressed heterologously in some bland background (e.g. *Xenopus* oocytes) that lack complicating extraneous factors. This analytical approach, however, does not lend itself to study of complex tissues and their control, precisely because of the nature of living systems. In order to study these problems in integrative physiology, we must be able to manipulate gene expression in specified tissues in the living organism.

Accordingly, we have spent the last four years developing an epithelial model which is uniquely amenable to physiological, biochemical, molecular and genetic analysis. The *Drosophila melanogaster* Malpighian tubule is the smallest insect epithelium yet studied; it is a simple epithelium of 145±1 principal cells. However, it is able to secrete fluid faster (on a per-cell basis) than any other known epithelium. Fluid secretion is driven by a plasma membrane V-ATPase, and is controlled by the cAMP, cGMP/nitric oxide and intracellular calcium signalling systems. Using enhancer-trap techniques, we have demonstrated previously unsuspected heterogeneity in this apparently simple epithelium, and we have been able to map boundaries to single cell resolution. The same technology now allows us to express genetic constructs of our choice in any tubule region or cell type that we have identified, and so provides a framework for novel experiments in integrative physiology that is not available for other tissues or other organisms.

DOES AMINOPEPTIDASE N PLAY A ROLE IN AMINO ACID TRANSPORT ALONG THE MIDGUT OF *BOMBYX MORI* LARVAE?

P. Parenti, P. Morandi, P. Consonni, M.G. Leonardi¹, B. Giordana¹
 Dipartimento di Fisiologia e Biochimica Generali, Università degli Studi di Milano, Italy - ¹ Dipartimento di Biologia, Università degli Studi di Milano, Italy

The aminopeptidase N catalyses the removal of amino acids from peptide substrates and has a broad specificity, preferring peptides with neutral N-terminal amino acids. Recently, it has been proposed that aminopeptidase N could be functionally linked to amino acid transport system in mammalian epithelia [Plakidou-Dymock et al., Biochem. J. 290 (1993): 59-65].

In lepidopteran midgut amino acid absorption occurs through a K⁺-dependent symport and aminopeptidase N represents one of the most abundant membrane enzyme. This peptidase was not removed by treatment with papain as in mammalian tissues, but it is partially released (up to 40% in *Bombyx mori*) after incubation with phosphatidylinositol-dependent phospholipase C. After the partial release of aminopeptidase N amino acid transport activity was unchanged. Therefore to explore the presence of a functional link between the aminopeptidase N and the lepidopteran K⁺/amino acid symport, kinetics experiments were performed for both of them. The affinities of neutral amino acids, amino acid analogues and inhibitors were assayed on both purified *B. mori* aminopeptidase N and the K⁺/amino acid symport. Our results failed to demonstrate any kinetic association between aminopeptidase and amino acid transport activities. Major evidences can be summarised as follows: i) bestatin and Zn⁺⁺ are strong inhibitor of aminopeptidase N activity at concentrations not affecting amino acid symport; ii) bestatin binds to and inhibits the K⁺/amino acid symport with a higher K_i than that for aminopeptidase N; iii) several leucine analogues are valid substrates only for the symporter; iv) the K⁺/amino acid symport appears strongly dependent on membrane electrical potential and an alkaline external pH.

05-025

AMINO ACID TRANSPORT IN COLEOPTERAN MIDGUT

J.J. Neal

Purdue University, Department of Entomology, West Lafayette, IN USA

Fundamental differences in midgut structure, physiology, brush border proteins and transporters among the coleopteran, *Leptinotarsa decemlineata* and other insect taxa are reviewed. *L. decemlineata* utilizes both ion-dependent and ion-independent transport systems. Like lepidopteran midgut ion-dependent transporters are stimulated by both Na⁺ and K⁺. K⁺-stimulated amino acid uptake into brush border membrane vesicles is the same in the presence or absence of a gradient but is slowed by an outward cation gradient. Because amino acids do not concentrate in *L. decemlineata* BBMVs, the *Bacillus thuringiensis* CryIIIA toxin does not inhibit ion-dependent uptake of amino acids. A model of amino acid transport in *L. decemlineata* is discussed.

05-026

GLUTAMATE TRANSPORT AND STORAGE BY VARIOUS INSECT EPITHELIA

S. Caveney, H. McLean, C. Yarema

Department of Zoology, University of Western Ontario, London, ON CANADA

Notably absent from the amino acid-rich blood plasma of caterpillars are significant amounts of two neuroactive dicarboxylic amino acids, L-aspartate and L-glutamate. Several tissues of the *Calpodex ethlius* caterpillar, such as the epidermis and the epithelia associated with the rectal complex, form large fluid-filled extracellular compartments that are isolated from the blood plasma and that periodically sequester millimolar concentrations of these two amino acids, presumably by transport mechanisms present in the epithelial plasma membranes. In the prepupal epidermis, glutamate storage in the ecdysial space peaks about 6 hr before pupation, but disappears rapidly and just before pupal ecdysis. The kinetics of glutamate reabsorption by the epidermis differs from that of other amino acids present in the ecdysial fluid, and uptake is independent of water removal from the ecdysial space by the caterpillar. In the subcuticular compartment of the rectal complex of the feeding caterpillar the concentration of these two amino acids climbs to 300-fold the micromolar levels found in the blood plasma and then drops to plasma values. This cycle of glutamate storage appears to be synchronized to the rectal cycle of water uptake associated with defecation. Alkaloids present in the food plant may also accumulate in the rectal complex during this cycle. The nature of the epithelial glutamate transport mechanisms involved will be discussed and contrasted with those of other insect tissues. These compartments may serve to provide large amounts of readily accessible glutamate for energy metabolism in these epithelia. The periodic nature of this storage suggests that epithelial activity is controlled by the cyclical release of neuropeptides that trigger glutamate transport into and out of these subcuticular spaces.

LOCUST ION TRANSPORT PEPTIDE: FUNCTION, PRIMARY STRUCTURE, CLONED DEOXYRIBONUCLEIC ACID AND EXPRESSION.

J.E. Phillips, J. Meredith, N. Audsley, H. Brock and D. Theilmann; Zoology Department, University of British Columbia, Vancouver, B.C., Canada.

Locust Ion Transport Peptide (ITP) purified from corpus cardiacum (CC) of *Schistocerca gregaria* stimulates Cl⁻, Na⁺, K⁺ and fluid reabsorption and inhibits acid secretion in anterior hindgut, which is functionally equivalent to the proximal tubules of vertebrate nephrons. A partial amino acid sequence and the polymerase chain reaction were used to obtain ITP cloned deoxyribonucleic acid (cDNA) encoding a 130 amino acid (aa) prohormone from which ITP is cleaved. ITP is a neuropeptide of 72 amino acids with terminal amidation, 3 sulphur bridges and a reduced molecular weight of 8564 Daltons. Insect Sf9 cells transfected with ITP cDNA using a baculovirus secreted a biologically active stimulant of locust hindgut transport. ITP synthesized by David King behaves like our purified ITP. ITP mRNA was detected in only brain and CC tissues. An ITP-related mRNA is present in several non-nervous tissues that do not stimulate the hindgut bioassay and its protein product (ITP-L) may have a negative feedback function. The ITP-L prohormone is 4 aa's longer than ITP and only 15 of the C-terminal 40 aa's are conserved relative to ITP. ITP has high sequence homology with a family of crustacean hormones having hyperglycaemic (CHH), molt-inhibiting (MIH) and vitellogenesis-inhibiting (VIH) actions (Meredith et al., J. Exp. Biol., In Press). MIH and CHH do not stimulate locust ileal Cl⁻ transport, but do inhibit such stimulation by ITP. A putative antidiuretic neuropeptide from *Locusta migratoria*, neuropepsins, does not stimulate either Cl⁻ or fluid absorption in hindgut of *Schistocerca gregaria*.

FIRST PRINCIPLES IN EPITHELIAL TRANSPORT PHYSIOLOGY: ELECTRICAL COUPLING OF TRANSCELLULAR AND PARACELLULAR TRANSPORT PATHWAYS

K. W. Beyenbach

Section of Physiology, VRT 926, Cornell University, Ithaca, NY, USA

Electroneutrality of solutions requires that for every cation transported across an epithelium an anion is moved in the same direction or another cation is moved in the opposite direction. In the case of Malpighian tubules, the secretion of K^+ and Na^+ into the tubule lumen is accompanied by an equivalent secretion of Cl^- or other ions. Since transepithelial secretion of K^+ and Na^+ is active (against electrochemical potentials), secretion of these cations must be transcellular, i.e. through epithelial cells that deliver the energy required for transport. In contrast, transepithelial secretion of Cl^- is passive (down the electrochemical potential). Requiring no cellular energy, transport of Cl^- may be paracellular, i.e. between epithelial cells (through septate junctions). Thus, active and passive transport pathways are parallel to each other. They form an intraepithelial electrical circuit where the transcellular active pathway may be described to consist of an electromotive force (E) and a transcellular resistance (R_c), while the paracellular passive pathway consists of only a shunt resistance (R_{sh}). Current in the circuit is equivalent to rates of transepithelial cation and anion secretion and regulated by changing E (metabolism, pumps), R_c and R_{sh} (conductances, channels). Mosquito natriuretic peptide affects primarily R_c , while leucokinin affects primarily R_{sh} , and CCRF-like diuretic peptide affects both in a dose dependent fashion. Effects on E, R_c and R_{sh} are additive, endowing the epithelium with transport rates that range from antidiuresis to diuresis.

ACID-BASE RELATIONS BETWEEN GUT, MALPIGHIAN TUBULES AND HAEMOLYMPH IN LEPIDOPTERAN LARVAE: SOME PIECES OF THE PUZZLE.

D.F. Moffett, A.R. Koch, B. Bower & P. Newberry

Department of Zoology, Washington State University, Pullman, WA USA.

The pH of body fluid compartments of 5th instar larvae of the tobacco hornworm *Manduca sexta* (Lepidoptera: Sphingidae) was evaluated by dissection after injection of pH-sensitive phenol red dye into the haemolymph. Consistent with previous work, the midgut contents are strongly alkaline and the ileal and rectal contents strongly acid throughout the 5th instar. In 5th instar larvae weighing <3 gm, all segments of the Malpighian tubules contain weakly acidic fluid; the midgut contents are strongly alkaline and the rectal contents are strongly acidic. At 3-4 gm body weight the ileal plexus fluid and the ileal tissue itself become strongly alkaline, indicating an increase in alkali recovery from the ileal contents. This picture is consistent with recycling of alkali from hindgut to midgut for resecretion, starting in the latter part of the 5th instar.

The midgut's alkali secretion rate *in vivo* was conservatively estimated at 54 μ Eq/hr for 8-10 gm animals, whereas the rate for isolated midgut is at least 10fold lower, even in solutions containing protein hydrolysate or haemolymph. The latter rate was insensitive to imposed transepithelial potentials, ruling out a passive contribution. To identify possible stimulatory or cooperative factors involved in alkali secretion *in vivo*, two *in situ* preparations were used; "headless", in which the midgut was cannulated from the anterior end of the animal, and "tailless", in which the last three segments were removed and the midgut was cannulated from the posterior end. Tailless preparations alkalinized injected solution markedly better than headless preparations, suggesting that head structures (e.g. Brain, salivary glands) are important for alkalinization, whereas recycling of alkali from the hindgut is not essential, at least in the 10 to 30 minute time scale of these experiments.

B.B. and P.N. were supported by Howard Hughes Undergraduate Fellowships.

HOW IS FLUID SECRETION BY INSECT MALPIGHIAN TUBULES CONTROLLED?

J.A.T. Dow¹, S.A. Davies¹, M.J. O'Donnell², G.R. Huesmann³, N.J. Tublitz³ and S.H.P. Maddrell⁴

¹Division of Molecular Genetics, Institute of Biomedical and Life Sciences, University of Glasgow, Glasgow G12 8QQ, U.K.; ²Department of Biology, McMaster University, 1280 Main St West, Hamilton, Ontario Canada L8S 4K1; ³Institute of Neuroscience, University of Oregon, Eugene, OR 97403, U.S.A.; ⁴Department of Zoology, Cambridge University, Downing Street, Cambridge, CB2 3EJ, UK

The Malpighian tubules of *Drosophila* are controlled by the cyclic AMP, cyclic GMP and calcium pathways. Using microelectrode techniques, we investigated whether they acted specifically on either cation or anion transport, or whether they activated both systems.

Stimulation with cyclic nucleotides alters the potential across principal cells, through the selective activation of an apical electrogenic V-ATPase. By contrast, manipulation of extracellular chloride levels, combined with stimulation with leucokinin, does not affect the potential profile across the principal cells, showing that chloride must pass through another route.

The cell-permeant calcium chelator, BAPTA-AM, was shown to suppress the action of leucokinins but not those of cAMP, or the neuronally-derived insect peptide CAP_{2b} or its intracellular messenger cGMP. This shows that leucokinins act through calcium and not through cyclic nucleotides, and that the cyclic nucleotide pathways do not co-activate the intracellular calcium pathway to exert their effects.

Taken together, these results show that leucokinin acts through intracellular calcium, independently of cAMP or cGMP, to raise chloride permeability of the epithelium. By contrast cyclic nucleotides act on the electrogenic cation transporting apical V-ATPase, with only a negligible effect on anion conductance, and without perturbing intracellular Ca^{2+} .

AMMONIA IS A FACTOR IN ALKALINIZATION OF MIDGUT CONTENTS BY *MANDUCA SEXTA* LARVAE (LEPIDOPTERA:SPHINGIDAE)

A.R. Koch and D.F. Moffett

Department of Zoology, Washington State University, Pullman, WA, U.S.A.

Lepidopteran larvae sustain luminal pH values as high as 10-11 in the anterior and middle midgut and values of 8-9 in the posterior midgut. These values are among the highest in living animals and cannot be explained by the transport processes presently known from studies of the midgut epithelium *in vitro*. We observed that the pH of fresh midgut contents from 5th instars of the tobacco hornworm undergoes a rapid drop of 2-3 pH units upon degassing, indicating loss of volatile alkali. Fresh midgut contents were collected directly into 0.1 N nitric acid and total ammonia content was determined from the formation of indophenol. Total ammonia ($NH_3 + NH_4^+$) averaged 2.63 ± 0.135 mM in anterior, 2.88 ± 0.304 in middle, and 1.92 ± 1.74 in posterior midguts. The partial pressure of NH_3 was calculated on the assumption that the pH was 10 in anterior and middle and 8 in posterior midguts. In anterior midgut, P_{NH_3} averaged 86.9 ± 0.97 mm Hg or more than a tenth of an atmosphere. Average P_{NH_3} in middle midgut was 80.6 ± 16.0 mm Hg. Because of the lower pH in posterior midgut, the average P_{NH_3} was 3.8 mm Hg. The high values are nonetheless underestimates, since some constituent of the gut contents destroys the indophenol produced in the assay. We propose that *in vivo* alkalinization includes two processes. One involves secretion of fixed alkali and may occur by mechanisms suggested by previous workers. This process takes dietary material from its initial pH value of 5.25 to approximately 8.0. The second process involves either direct secretion of NH_3 by the midgut epithelium or enzymatic production of NH_3 within the gut contents. This process brings the pH of gut contents to above 10.

ONTOLOGY OF RECTAL WATER VAPOUR ABSORPTION

John Noble-Nesbitt

School of Biological Sciences, University of East Anglia, Norwich
NR4 7TJ, UK

The eggs and the short-lived first instar nymph of the firebrat, *Thermobia domestica*, are incapable of absorbing water vapour. They owe their survival in desiccating conditions to the water reserves supplied by the mother in the egg and to mechanisms for limiting transpiratory water loss. This is probably one reason for the very short-lived first instar. At this stage, only the rudiments of the proctodaeum have developed. Continuous mass records show low rates of mass (water) loss over long periods in high relative humidity (84% RH). Hatching and moulting are recorded as small abrupt mass losses, as hatching or moulting fluid evaporates, so readily distinguishing each instar.

During the second instar, onset of vapour absorption is shown by small sporadic bouts of mass gain, especially towards the latter part of the instar. This coincides with partial development of the posterior rectal sacs, which continue to develop throughout this instar and reach full development in the third and fourth instars. Third instar nymphs are capable of sustained vapour absorption over extended periods at high rates. Early instar nymphs reach maximal rates of absorption normalised to body mass well in excess of the maximal rates found in later nymphs and adults, when a linear allometric relationship is found. Maximal rates of absorption recorded for late instar nymphs and adult firebrats consistently approximate to 1% body mass per hour. Early second instar nymphs underperform against this standard but by mid-instar they breach this standard and by the end of the instar rates are more than doubled. In the third and fourth instars, maximal rates reach close to 3% body mass per hour. This early period of non-allometric development of vapour absorption is likely to be linked to the need for rapid and sustained early growth.

05-034

THE METABOLISM OF SUCROSE AND AMINO ACIDS AND OSMOREGULATION IN APHIDS

J D Rhodes, P C Croghan and A F G Dixon

School of Biological Sciences, University of East Anglia, Norwich
NR4 7TJ, UK

Avoidance of dehydration of the haemolymph due to a very high dietary osmotic pressure is a major problem for aphids. The adaptations include a high osmotic pressure in the haemolymph and polymerisation of dietary sugars in the gut to form oligosaccharides. The rate of ingestion of a 25% w/v sucrose diet was $12.4 \text{ nl mg}^{-1} \text{ h}^{-1}$ and the excretion rate was $5.3 \text{ nl mg}^{-1} \text{ h}^{-1}$. Of the ingested diet 69% of the sucrose and 94% of the amino acids were assimilated. While feeding on a 25% w/v sucrose diet, sucrose was respired at the rate of $1.32 \times 10^{-6} \text{ mmol mg}^{-1} \text{ h}^{-1}$, equivalent to $0.35 \mu\text{l O}_2 \text{ mg}^{-1} \text{ h}^{-1}$. Sucrose was oxidised in preference to amino acids. The haemolymph of *A. pisum*, feeding on artificial diet containing 25% w/v sucrose, was found to contain two main sugars: trehalose (255 mM) and fructose (129 mM). No sucrose was found in the haemolymph. The honeydew sugars (350 mM) of aphids fed the same diet were mainly oligosaccharides (220 mM), which accounted for 85% of the total ^{14}C in the sample. It was estimated that the polymerisation of sucrose was responsible for a reduction in concentration of approximately 34%. At low dietary sucrose concentrations (5 to 10%), the honeydew contained mainly mono and disaccharides. At dietary sucrose concentrations of 15% and greater, oligosaccharides were predominant. This is consistent with the idea that osmoregulation is by oligosaccharide synthesis. Analysis of stomach contents revealed that oligosaccharide synthesis occurs there, while tissue incubation showed that the gut is much more active in oligosaccharide synthesis than the eviscerated body tissues. The function of the filter chamber, found in some aphid species, is considered and it is suggested that this is a mechanism for reducing the osmotic pressure of the ingested diet.

05-033

DISCONTINUOUS GAS EXCHANGE AND THE CUTICULAR AND RESPIRATORY COMPONENTS OF WATER LOSS IN THE COCKROACH *DIPLOPTERA PUNCTATA* (ESCHSCHOLTZ) (DICTYOPTERA: BLABERIDAE)

A. G Appel

Department of Entomology, Auburn University, Auburn, AL USA

Respiration and water efflux patterns in the pseudoviviparous cockroach *Diploptera punctata* (Eschscholtz) were measured simultaneously in a flow-through system using dual-wavelength infrared absorbance. Only cockroaches in a 'resting' posture exhibited cyclic discontinuous gas exchange with a frequency of 4.1 mHz. There was no obvious flutter phase prior to the main burst emission of CO_2 , however some individuals emitted several small bursts of CO_2 prior to the main burst. Unlike other insects, there was no relationship between the frequency of gas exchange cycles and the volume of CO_2 released. Therefore, to accommodate increasing CO_2 loss, *D.*

punctata increase both burst and interburst \dot{V}_{CO_2} . Water loss was constant during the interburst intervals representing cuticular water loss. Water loss increased from interburst levels only during bursts of CO_2 emission. Respiratory water loss accounted for only 8.4% of all water lost during a respiratory burst, and <5% of total body water loss. Discontinuous gas exchange in this species affords relatively little protection from desiccation.

05-035

LOCALIZATION OF AMINO ACID ABSORPTION SYSTEMS IN THE LARVAL MIDGUT OF *MANDUCA SEXTA*

M G Wolfersberger

Department of Biology, Temple University, Philadelphia, PA, USA

The midgut of *Manduca sexta* larvae is composed of three morphologically distinct regions: anterior, middle and posterior. The folding of the epithelium as well as the structure of columnar and goblet cells varies among the regions. In the middle region columnar cell structure changes gradually from anterior type to posterior type. On the basis of cell structure it has been postulated that nutrient absorption may be confined to the posterior type columnar cells.

Larval *M. sexta* midgut has been shown to contain at least three distinct systems for absorption of amino acids from the lumen contents by amino acid- K^+ symport. Brush border membrane vesicles (BBMV) were prepared separately from anterior and posterior midgut regions and assayed for the membrane marker enzyme aminopeptidase as well as for the presence and properties of the three amino acid- K^+ symport systems. Although the specific aminopeptidase activity in the posterior homogenate was nearly twenty times that in the anterior homogenate, enrichment in aminopeptidase activity was similar for BBMV from both regions. Symport systems for absorption of neutral amino acids were found only in posterior midgut BBMV. Proline uptake by anterior BBMV increased linearly with proline concentration but the dependence of the rate of uptake of other neutral amino acids on substrate concentration was biphasic; indicating the presence of a uniporter. Cationic amino acid- K^+ symport was found in both anterior and posterior BBMV. Substrate affinities were consistent with the same system being present in both anterior and posterior BBMV but the specific activity of the system was three times greater in the anterior BBMV.

05-036

CRYIAa δ -ENDOTOXIN FROM *BACILLUS THURINGIENSIS* EFFECTS K^+ /AMINO ACID SYMPORT IN *BOMBYX MORI* LARVAL MIDGUT.

MG Leonardi, B Giordana, P Parenti¹
Dipartimento di Biologia - 1 Dipartimento di Fisiologia e Biochimica Generali, Università di Milano, Milano Italia

The inhibition of K^+ -dependent amino acid transport into brush border membrane vesicles (BBMV) from the midgut of susceptible lepidopteran larvae provides a reliable test for the evaluation of *Bacillus thuringiensis* (Bt) δ -endotoxin activity and specificity. An activated preparation of CryIAa toxin produced a specific dose-dependent inhibition of K^+ -dependent leucine transport into midgut BBMV from *Bombyx mori*. The activity of the δ -endotoxin was observed also in the absence of K^+ , which suggests its direct interaction with the K^+ /amino acid symporter (P.Parenti et al. J Invertebrate Pathol. 65,35-42, 1995). K^+ permeability and cation-dependent amino acid translocation in BBMV can be evaluated by monitoring the fluorescence of the voltage-sensitive cyanine dye 3,3'-diethylthiacarbocyanine iodide(DisC₃5). The symporter ability to accept Na^+ instead of K^+ was exploited and the dissipation of an imposed inside-negative potential (K^+ gradient in>out and valinomycin) was registered in the presence of a Na^+ gradient (out>in) and of the amino acid. The fluorescence quenching dissipated more rapidly when the amino acid was present. Preincubation of BBMV with CryIAa caused a significant decrease of the amino acid-dependent recovery of fluorescence, whereas K^+ permeability was unaffected. In the isolated midgut Bt δ -endotoxins inhibit leucine transepithelial fluxes as well as the electrical potential difference (PD). However the strong inhibition of amino acid flux showed a different timing compared to the drop of PD.

05-038

PLUTELLA XYLOSTELLA: MIDGUT ELECTROPHYSIOLOGY: TRANSEPITHELIAL & CELL RESISTANCES, EFFECTS OF K^+ & Ba^{++}

N. De Decker, J. Van Rie*, P. Steels, E. Van Kerkhove
Limburgs Universitair Centrum, Dept. MBW-Fysiologie, B3590 Diepenbeek, Belgium; * Plant Genetic Systems, B9000 Gent, Belgium.

Plutella xylostella (Px) midgut has a high transepithelial potential, V_{te} , of 40 mV (lumen positive) and resistance, R_{te} , of 174 $\Omega \cdot cm^2$ (De Decker *et al.*, 1995, Pflügers Arch. (abstract) in press; De Decker *et al.*, 1996 Abstract, Physiol. Soc. Meeting, Manchester, (to be published in J. Physiol.). If we consider an epithelium to consist of a cellular (R_{cell}) and a intercellular (or shunt) resistance, R_{sh} , in parallel, changes in R_{cell} will be reflected in significant alterations in R_{te} only if R_{cell} (i.e. the sum of the luminal, R_{lu} , and the basolateral membrane resistance, R_{bl}) is comparable to, or lower than R_{sh} . In the present study we investigated whether we could detect a change in R_{cell} with measurements of R_{te} . An isolated Px midgut was mounted in a luminal perfusion set-up. V_{te} was measured and current pulses were applied across the epithelium to calculate R_{te} using the appropriate cable equations (Boulpaep & Giebisch, 1978, In Martinez-Maldonado ed.: *Meth. in Pharmacology*, vol. 4b, 165-193, Plenum, London). Cells were impaled from the bath side and the membrane potential V_{bl} was measured. Voltage deflections caused by the current pulses allowed us to derive the voltage divider ratio, VDR, which is an estimate of the luminal, R_{lu} , over the basolateral membrane resistance, R_{bl} . If the basolateral membrane holds a K^+ conductance its resistance can be altered by changing the bath K^+ concentration and by applying the K^+ channel blocker, Ba^{++} , to the bath. In paired experiments a tenfold decrease of the bath K^+ reversibly hyperpolarized V_{bl} from -3 ± 1 to -17 ± 4 , $n=21$, $p < 0.01$, paired Student's t-test. This confirms the presence of a K^+ conductance in the cell membrane, as in most animal cells. At the same time R_{te} increased reversibly with about 10 % (from 139 ± 9 to 156 ± 11 , $n=21$, $p < 0.001$) and the VDR decreased with a factor of 2 (from 12 ± 1 to 7 ± 1 , $p < 0.02$). Lowering the bath K^+ and applying Ba^{++} (6 mM) at the same time is expected to cause even more pronounced changes: R_{te} increased reversibly with about 30 % (from 150 ± 9 to 200 ± 12 , $n=24$, $p < 0.001$) and VDR decreased with a factor of 3 (from 16 ± 2 to 5 ± 1 , $p < 0.001$). The data show that changes in membrane properties as reflected in VDR, provoke measurable changes in Px midgut R_{te} . The method can be used to detect δ endotoxin effects on luminal membrane resistance (De Decker *et al.*, 1996).

05-037

CRYIIIA EFFECTS ON AMINO ACID TRANSPORT

Jonathan J. Neal and Young Seok Hong
Purdue University, Department of Entomology, West Lafayette, IN USA

Bacillus thuringiensis CryIIIA δ -endotoxin does not affect the transport of tyrosine and leucine into brush border membrane vesicles (BBMV) from midgut of a target insect, the Colorado potato beetle or jejunum of a non-target vertebrate, the rabbit, even at very high concentrations. The CryIIA toxin was six orders of magnitude more potent in inhibiting tyrosine transport into *Manduca sexta* BBMV than was the CryIIIA toxin. Both toxins eliminated the overshoot concentration of amino acid in *M. sexta* BBMV in the presence of an inward KSCN gradient. The physiology of the midgut transporters that leads to these results is discussed.

05-039

ACTIVATION OF THE CRYIIIA TOXIN OF *BACILLUS THURINGIENSIS* SUBSP. *TENEBRIONIS*: A COMPARATIVE ANALYSIS

E. Franken¹, L. Potvin², J.L. Schwartz³ and W. Schnetter¹
1 Zool. Inst. II, University of Heidelberg, Heidelberg, Germany - 2 GRTM, Université de Montréal, Montréal, Canada - 3 NRC-BRI, Montréal, Canada

The pH values in the fore- and midgut of larvae of the Colorado potato beetle CPB (*Leptinotarsa decemlineata*) range between pH 4 and pH 7. The gut proteolytic enzymes have their highest proteolytic activity under moderately acidic pH conditions. Most of the proteases are cystein-dependent, no trypsin-like enzymes could be detected. The pH conditions in the midgut of the European cockchafer (*Melolontha spec.*) are neutral to alkaline (pH 7 to pH 9.5) with trypsin-like proteases as main proteolytic enzymes.

The crystal toxin of *Bacillus thuringiensis* subsp. *tenebrionis* is activated at acidic pH by CPB proteases. Treatment with gut fluid of the European cockchafer under alkaline conditions results in a 55 kDa toxin fragment which in bioassay is inactive against CPB.

Planar lipid bilayer (PLB) studies with CPB gut fluid activated CryIIIA reveal a channel with a main conductance level of 512 pS and a subconductance level of 128 pS under symmetrical conditions. The channel is selective for monovalent cations and voltage-independent. The channel formed by trypsin treated CryIIIA toxin has a main conductance level of 440 pS.

In order to assess the discrepancy between biological activity and channel formation in PLB experiments, a 38.8 kDa toxin fragment was produced by hydroxylamine cleavage covering residues 1 to 337 of the activated CryIIIA toxin and representing the proposed pore-forming domain I and a small portion of domain II (structure data according to Li *et al.* 1991). PLB analysis of this fragment revealed a channel with conductance levels between 116 pS and 270 pS under symmetrical conditions.

05-040

MIDGUT MEMBRANE PORE FORMATION BY *BACILLUS THURINGIENSIS* INSECTICIDAL PROTEIN TOXINS

D. J. Ellar

Biochemistry Department, Cambridge University, Tennis Court Road, Cambridge, CB2 1QW, UK

The bacterium *Bacillus thuringiensis* produces specific insecticidal protein toxins (δ -endotoxins) grouped into two families - Cry and Cyt toxins - by sequence similarity. Both types of δ -endotoxin bind to insect-specific receptors on the surface of midgut epithelial cells and insert into the cell membrane to form leakage channels that result in cell death by colloid osmotic lysis. The X-ray structure of the first Cry toxin revealed putative membrane insertion and receptor binding domains whose functions have been explored by mutagenesis. The first Cyt toxin structure has now been described and is entirely different from the Cry toxins - despite their similar toxic mechanism. The first two Cry toxin receptors have recently been cloned and sequenced. These receptors are transmembrane proteins exposed on the lumen surface of midgut epithelial cells. Using *Manduca sexta* midgut brush border membrane vesicles (BBMV) we previously analysed the action of the δ -endotoxin Cry1Ac using a light-scattering assay (Carroll and Ellar 1993, *Eur. J. Biochem.* **214**, 771-778). This assay monitors vesicle volume changes and the effect of toxins by following the associated changes in scattered-light intensity as vesicles shrink and swell in an osmotic gradient. Activated Cry1Ac increased *M. sexta* BBMV membrane permeability for cations, anions and neutral solutes. However, vesicle volume is not the sole determinant of scattered light intensity. Solute-related refractive index changes and artefacts associated with vesicle motion and aggregation limit the quantitative application of this method, although it is still uniquely valuable in comparing different toxins under identical experimental conditions (Wolfersberger *et al.* 1996, *Appl. Environ. Microbiol.* **62**, 279-282). An extension of this approach based on the self-quenching of an entrapped fluorophore (Chen *et al.* 1988, *Biochemistry* **27**, 5713-5718) will be described. This allows quantitative comparisons of membrane permeability changes to different test solutes to be made. Changes in vesicle volume are followed by the resulting change in fluorescence of trapped carboxyfluorescein as the BBMV shrink and swell.

05-042

REGULATION OF TWO ECDYSONE RECEPTOR ISOFORMS AND ULTRASPIRACLE DURING *MANDUCA* DEVELOPMENTL. M. Riddiford, M. Jindra, M. Asahina, K. Hiruma, F. Malone
Department of Zoology, University of Washington, Seattle, WA USA

During growth, molting, and metamorphosis of the tobacco hornworm, *Manduca sexta*, the developmental profiles in the epidermis for both mRNA and protein of the ecdysone receptor (EcR) and its heterodimeric partner Ultraspiracle (USP) differ. From the first instar on, USP is ubiquitously expressed with some fluctuations during the molts when a second transcript is also detected. After pupal commitment, USP mRNA remains high, whereas the protein transiently disappears from the nucleus, then reappears at the onset of pupal differentiation. During the adult molt, USP is highest at the onset of cuticle formation. By contrast, EcR levels are dependent on the ecdysteroid titer with EcR-B1 present at low levels throughout the intermolt periods of the 4th and 5th instars, then induced by low levels of 20-hydroxyecdysone (20E) ($ED_{50}=60$ ng/ml) at the onset of the larval, pupal and adult molts and at the time of pupal commitment. In the epidermis EcR-A is present at much lower levels except at the time of the peaks of the ecdysteroid titers for the larval and adult molts when it transiently appears as cuticle deposition begins. At the onset of metamorphosis during pupal commitment, EcR-A appears later than EcR-B1 consistent with its higher $ED_{50}=110$ ng/ml, then stays high through the onset of pupal differentiation. In contrast to *Drosophila* where EcR-A predominates at pupariation, both EcR-A and -B1 are high in *Manduca* wing discs during the onset of pupal development and show two peaks of expression during adult development with EcR-A persisting as the cuticle is being deposited. Thus, EcR-B1 is associated with maintenance and early predifferentiative events during a molt whereas EcR-A is primarily associated with the differentiative event of cuticle deposition, but also is involved with the switching that must occur in the polymorphic epidermis.

Functional and phylogenetic studies of the pore formation domain from the *Bacillus thuringiensis* delta-endotoxins.

A.Bravo, A.Lorence, J.Sanchez, M.E.Nuñez.

Bacillus thuringiensis are Gram positive bacteria which produces proteinaceous inclusions during sporulation, these inclusion are composed of proteins known as insecticidal crystal proteins (ICPs) or δ -endotoxins, which are highly toxic, to a wide variety of important agricultural and health-related insect pests. A critical step for insecticidal activity is the binding of activated toxins to receptors located on the apical microvilli membrane of epithelial midgut cells (Hofmann *et al.*, 1988; Van Rie *et al.*, 1990a). The interaction of the toxin with those receptors triggers the opening of ionic channels (Sacchi *et al.*, 1986; Lorence *et al.*, 1995). These channels shunt the electrogenic pump potential difference and disrupt ion gradients and pH regulation, causing cell lysis, gut paralysis and death of the insect. The crystal structure of Cry3A (coleopteran specific) and Cry1Aa (lepidopteran specific) toxins have been reported (Li *et al.* 1991; Grochulski *et al.* 1995). Both toxins shares 36% amino acid identity and the two structures show high overall similarity. Both are globular molecules composed of three distinct domains connected by single linkers. Domain I has been implicated in the ion channel formation in the membrane. Domain II has been described as the specificity-determining domain. Domain III is proposed to stabilize the toxin by protection from proteolysis (Li *et al.* 1991). Experimental data from several laboratories have shown that domains from Cry proteins are structural independent. Isolation of domain I (Walters *et al.* 1993, von Tersch *et al.* 1994) and α -helix peptides (Cummings *et al.* 1993; Gazit *et al.* 1994) retains its ability to form cation channel formation in planar lipid bilayers. There are no reports of Domain II or Domain III isolation and expression, however exchanging sequence segments within domain II and domain III resulted in changes in specificity. These observations supports that Bt toxins are modular in structure and suggest that the different domains could have evolved independently. In this work we will present the characterization of the ion channel formed by Cry1Ac, Cry1C and Cry1D toxins in the presence and in the absence of their receptors. Our data shows that all toxins forms cation channels which are not highly selective among different monovalent cations, but they differ in their ionic conductances. We will show data regarding the analysis of mutants affected in alpha-helix 5, that are altered in the ion channel formation. Finally a phylogenetic relationship among the different domain I from all reported delta-endotoxins will be discussed.

DEVELOPMENTAL PROFILES OF EcR EXPRESSION DURING WING MORPHOGENESIS IN *BOMBYX MORI*.H. Fujiwara and M. Kamimura¹Department of Biological Sciences, University of Tokyo,
Tokyo -1 National Institute of Sericultural and
Entomological Science, Tsukuba, Japan

The wing disc of insects changes dramatically in size and shape during metamorphosis and thus is a good model to study the mechanism of tissue differentiation. The metamorphic processes are triggered by ecdysone, which actions are mediated by the ecdysone receptor (EcR) to control the gene expression in the target tissues. We identified the ecdysone receptor gene (BmEcR) and studied its mRNA expression during wing formation in *Bombyx mori*. The expression of B1 form of the BmEcR was induced at day 4-5th, maximal on the day of wandering and repressed during pharate pupa. The ecdysteroid titer, the EcR expression pattern and the morphological changes seem to be closely related. The expression pattern of EcR in wing discs is also similar in *Manduca sexta*, suggesting that the temporal pattern is essential to form the wings during metamorphosis among lepidopteran insects. This idea has been further supported by an observation that the mRNAs of EcR B1 and A form are not normally expressed in the wing discs of a wingless mutant, fl (flügellos) of the silkworm. We will discuss about the role of the EcR on the wing morphogenesis through comparison between *Bombyx* and *Manduca* system and between the wild type and fl mutant of the silkworm.

STEROID RECEPTOR SUPERFAMILY GENES AND THEIR RELEVANCE TO DIAPAUSE AND EMBRYOGENESIS OF *BOMBYX MORI*

T. Yaginuma, T. Niimi¹, O. Yamashita
Laboratory of Sericulture and Entomoresources, School of Agricultural Sciences, Nagoya University, Chikusa, Nagoya (464-01), Japan - 1 Present address: Department of Cell Biology, Biozentrum, University of Basel, CH-4056, Basel, Switzerland

With onset of embryonic diapause of *Bombyx mori*, glycogen converts into sorbitol and glycerol. At diapause termination which is caused by cold-acclimation, an utilization of sorbitol for re-synthesis of glycogen is controlled by sorbitol dehydrogenase, of which gene expression is induced by cold acclimation. Further to understand molecular mechanism how cold temperature works on the gene for sorbitol dehydrogenase, the gene structure was analyzed. Some nucleotide sequences similar to cis-elements which are recognized and bound by steroid receptor superfamily members such as COUP-TF/Seven up, FTZ-F1 and DHR39, were found in 5'-up stream region of the gene for sorbitol dehydrogenase. cDNAs for *Bombyx* homologs of Seven up, DHR 39 and EcR were cloned and sequenced, and the amounts in mRNAs for Seven up, BHR 39, FTZ-F1 and EcR were examined in eggs during diapause and embryogenesis. Especially, the profiles of gene expressions for *Bombyx* homologs of Seven up and EcR are discussed in relation to the gene expression for sorbitol dehydrogenase during diapause and embryogenesis.

1 CSIRO Division of Biomolecular Engineering, North Ryde, Australia.

Aphids have been refractory to classical methods of endocrinological investigation because of their small size. Their polyphenism (winged or wingless, parthenogenetic or sexual) and their very rapid viviparous parthenogenetic reproduction have long been suspected of being under control of ecdysone and juvenile hormone. There is increasing evidence from other insects that spatial and temporal ecdysteroid receptor expression is related to metamorphosis (and by extrapolation, to polyphenism). We have prepared cDNA libraries from third instar *Myzus persicae*, a cosmopolitan aphid which serves as vector of viral diseases to many economically important crops. The libraries were probed initially with sequence for the DNA-binding domain from the *Drosophila* ecdysteroid receptor gene (*DmEcR*), and subsequently with a probe derived by PCR from *M. persicae* genomic DNA. We have located, cloned and sequenced from our random-primed library a 700 bp fragment with many features suggesting that it is part of an aphid *EcR*. It contains a region coding for a DNA-binding domain and exhibits 86-88% identity, and 91-95% similarity, with other known *EcRs*. The initial fragment does not include the region coding for the hormone-binding domain, and a full-length insert is being sought in the oligo-dT primed library. The complete sequence will enable us to commence expression studies, and eventually to study the spatial and temporal distribution of *EcRs* in aphids in relation to their unusual biology.

05-045

MOLECULAR ANALYSIS OF ECDYSTEROID ACTION DURING MOSQUITO VITELLOGENESIS
A.S. Raikhel, M.Z. Kapitskaya, S. Wang, A. Biran, W. A. Pierceall¹ and W. A. Segraves¹
Department of Entomology, Michigan State University, East Lansing, MI USA - 1 Department of Biology, Yale University, New Haven, CT USA

In mosquitoes, 20-hydroxyecdysone (20E) plays a critical role in regulation of vitellogenic events in the fat body and ovaries. To elucidate the ecdysteroid regulatory cascade controlling mosquito vitellogenesis, we cloned the cDNAs encoding the *Aedes aegypti* ecdysteroid receptor (AaEcR) and its heterodimeric partner, the Ultraspiracle homolog (AaUSP). Two major transcripts of AaEcR (4.2 and 6 kb) are expressed during the previtellogenic and early vitellogenic period in both the fat body and ovaries. Four AaUSP transcripts, 1.8, 2.2, 2.5, and 3.0 kb, are expressed in these vitellogenic tissues with the smaller transcripts predominating in the ovary and the 3.0-kb transcript in the fat body. Two cloned AaUSP isoforms differ in their A/B domains. Both AaUSP isoforms form active heterodimers with AaEcR which bind *Drosophila* hsp27EcRE. 10⁻⁸ M 20E is required for maximal DNA binding activity of AaEcR/AaUSP. Experiments utilizing 20E and cycloheximide showed that the action of 20E on the target vitellogenic genes, vitellogenin and vitellogenic carboxypeptidase, is indirect. Therefore, we have begun the search for the early genes mediating 20E response in the mosquito by cloning the *Drosophila* E75 homolog (AaE75). Analysis of the AaE75 gene and cDNAs showed that three isoforms (A, B, and C) result from alternative exon usage and are expressed in both the ovary and fat body during vitellogenesis.

05-047

MOLECULAR BASIS FOR SELECTIVE INSECT TOXICITY OF THE NON-STEROIDAL ECDYSTEROID AGONIST, RH 5992

Tarlochan S. Dhadialla and Dean E Cress
Rohm and Haas Company, 727 Norristown Road, Spring House, PA 19477

RH 5992 (Tebufenozide, MIMIC[®], CONFIRM[®]), the first non-steroidal ecdysteroid agonist undergoing worldwide commercial development, manifests its toxicity in lepidopteran larval pests via interaction with the ecdysteroid receptors (EcR). Interestingly, in spite of the fact that most insects use 20-hydroxyecdysone (20E) as the molting hormone, the action of which is mediated via the ecdysteroid receptors, RH 5992 is toxic only to lepidopteran larvae. Our previous experiments to explain this selective toxicity of RH 5992 indicated that there were no differences in the transport and metabolism of RH 5992 in susceptible lepidopteran and non-susceptible coleopteran insects tested. We have carried out additional experiments to understand the molecular basis of the selective toxicity of RH 5992. Although, RH 5992 binds to various EcRs in cellular extracts or to EcR/ultraspiracle (USP) proteins produced *in vitro*, it does so with significantly different affinities. Ligand-induced changes in EcRs can be visualised by subjecting radiolabeled EcR in ligand-EcR-USP complexes to partial proteolysis followed by analysis of the digests by SDS-PAGE and fluorography. Results of such experiments with Muriesterone A and RH 5992 and one lepidopteran and two dipteran EcRs revealed differences in RH 5992 induced conformational changes in different EcRs. Muriesterone A induced conformational changes in all the three EcRs. The significance of these results will be discussed with respect to the selective toxicity of RH 5992 in insects.

LEPIDOPTERAN AND DIPTERAN 20-HYDROXY-ECDYSONE RECEPTORS: STRUCTURAL AND FUNCTIONAL SIMILARITIES AND DIFFERENCES

L. Swevers, L. Cherbas¹, P. Cherbas¹ and K. JarrouDepartment of Medical Biochemistry, The University of Calgary, Calgary, AB T2N 4N1, Canada - ¹ Department of Biology, Indiana University, Bloomington, IN 47405, U.S.A.

The *Drosophila* ecdysone receptor (DmEcR) functions as an obligate heterodimer with another nuclear receptor, DmUSP. Both EcR and USP homologs have been cloned in the domesticated silkworm, *Bombyx mori*. Their sequences differ considerably from those of their *Drosophila* counterparts; only within their DNA-binding domain do the receptors show high levels of sequence conservation. Because the sequence changes in the ligand-binding and transactivation domains of the receptors may reflect functional differences, we have begun testing whether *Drosophila* and *Bombyx* receptor components are interchangeable.

Our data indicate that the components of a functional ecdysone receptor complex are conserved among Diptera and Lepidoptera. Upon dimerization with BmCF1 (the silkworm homolog of USP), BmEcR binds ¹²⁵I-iodoponasterone A with a K_d of 1.1 nM, and forms a specific, high affinity complex with a *Drosophila* ecdysone-response element (EcRE). BmEcR can also substitute for DmEcR in an EcR-deficient *Drosophila* tissue culture line, stimulating transactivation of an ecdysone-inducible reporter gene construct.

However, significant differences were observed between DmEcR and BmEcR in their capacity to induce ecdysone-dependent gene expression in a *Drosophila* cell line that is deficient in endogenous EcR; gel retardation assays also revealed that BmEcR/DmUSP heterodimers bind more stably to the *Drosophila* EcRE than BmEcR/BmCF1 ones, reflecting differences in the dimerization properties of Dipteran and Lepidopteran receptors and differences in the stability of complexes formed between the two heterodimers on the *Drosophila* EcRE. Thus, it appears that despite the functional equivalence of the ecdysone receptor components, differences do exist with respect to the ecdysone response between Lepidoptera and Diptera.

We are currently conducting additional binding assays to determine the stability of complexes formed between DmEcR/BmCF1 heterodimers and the *Drosophila* EcRE. Work is also in progress to isolate EcRE sequences from lepidopteran (*Bombyx*) ecdysone early response genes.

05-050

CROSS-TALKING AMONG *DROSOPHILA* NUCLEAR RECEPTORS AT THE PROMISCUOUS HORMONE RESPONSE ELEMENT OF THE *ng-1* INTERMOULT GENE

S. Crispi, P.P. D'Avino, E. Giordano, A. Pastore, G. Testa and Maria Furia

Dipt. di Genetica, Biologia Generale e Molecolare, Università di Napoli Federico II, Napoli, Italia.

In *D. melanogaster*, three temporally distinct ecdysone-responsive puff sets, the so-called intermolt, early and late puffs, have been described on the salivary gland polytene chromosomes. The group of "intermolt" puffs is the first that is transcriptionally active during the third instar. Intermolt genes encode salivary gland-specific proteins, so that their expression is part of the gland-specific pre-metamorphic response to ecdysone. We are studying the early hormonal response by focusing on *ng-1* and *ng-2*, a pair of highly homologous genes mapping at the 3C intermolt puff. The *ng*-genes start to be transcribed at the beginning of the third instar, when the ecdysteroid titer is still low, to be repressed at the onset of the wandering phase, in concomitance with the induction of the other intermolt genes. This peculiar developmental expression profile provides an unique opportunity to investigate the hormonal regulatory hierarchy at a developmental window not widely explored. Two EcREs of identical sequence have been identified within the coding region of the *ng-1* and *ng-2* intermolt genes (D'Avino et al., Mol. Cell. Endocrinol. 113:1-9, 1995). These EcREs have now been characterized at the molecular and functional level. The ability of binding the EcR/USP heterodimer has been shown to depend on two directly repeated half-sites separated by 11bp (DR11). As structurally analogous vertebrate HREs composed of widely spaced direct repeats, the *ng*-EcREs act as promiscuous response elements able to bind several *Drosophila* nuclear receptors, thus offering a good experimental model system to studying receptor cross-talking. At the functional level, transient expression and P-element mediated transformation experiments show that the *ng*-EcREs act as enhancers to direct high-level *ng-1* and *ng-2* expression.

05-049

MODULATION OF HORMONE AND DNA BINDING BY BmCF1 A LEPIDOPTERAN HOMOLOGUE OF *ultraspiracle*, PARTNER OF ECDYSONE RECEPTOR AND THE NGFI-B INSECT HOMOLOGUE BHR38George Tzertzinis^{1,2}, Tarlochan S. Dhaddiala², Tatjana Kozlova¹, James Sutherland¹ and Fotis C. Kafatos¹
European Molecular Biology Laboratory, Heidelberg, Germany- Rohm and Haas Company, Spring House PA, USA

BmCF1 is a *Bombyx mori* homologue of the *Drosophila* *ultraspiracle* (USP), having greater than 95% identical amino acid residues in the zinc finger domain and 50% in the ligand domain. BmCF1, like USP but unlike its mammalian homologue RXR, does not show any hormone or DNA binding activity alone, but it readily heterodimerises with EcRs to bind both hormone and DNA targets. We studied the properties of homospecific (*Drosophila*) and heterospecific (*Drosophila/Bombyx*) EcR/USP heterodimers with respect to their hormone and DNA binding properties.

Comparison of the affinities of ecdysteroids to DmEcR/BmCF1 and DmEcR/USP suggests that BmCF1 can substitute for USP in modulating ecdysteroid binding by EcR. Surprisingly though, its strongly conserved DNA-binding zinc finger domain seems to display different DNA binding properties and thus affect the specificity of the formed heterodimers.

Recently we isolated a new partner of USP, hormone receptor 38 (DHR38 and BHR38 from *Drosophila* and *Bombyx* respectively) a homologue of the mammalian NGFI-B type receptors which were originally thought to function exclusively as monomers.

Both *Bombyx* and *Drosophila* HR38 heterodimerise avidly with BmCF1/USP constituting an additional to EcR partner of USP. The strong binding of HR38 to BmCF1 and USP precludes USP/EcR heterodimerisation and consequently, ecdysone response. The precise role of HR38 in the ecdysone response mechanism is under current study.

05-051

ACCESSIBILITY OF ECDYSONE RECEPTOR BINDING SITES IN *CHIRONOMUS* POLYTENE CHROMOSOMESM. Lezzi, C. Elke, M. Vögeli, F. Gatzka, P. Rauch¹, M. Spindler-Barth¹, K.-D. Spindler¹Institut für Zellbiologie, ETH, Zürich, Switzerland - ¹ Lehrstuhl für Hormon- und Entwicklungsphysiologie, Heinrich-Heine-Universität, Düsseldorf, Germany

The ecdysone receptor (EcR) is a transcription factor whose functioning depends not only on the nuclear concentration level of itself and of its heterodimerization partner USP but also on the cellular titer of its ligand (i.e. ecdysteroids, Ec) as well as on the accessibility of cognate response elements in DNA (EcREs) flanking Ec-responsive genes. In situ studies with polytene chromosomes of larval salivary glands of *Chironomus tentans* suggested a model in which the state of chromatin condensation would control access of Ec-activated EcR/USP complexes to EcREs in specific chromosomal loci. In order to test this model the genes coding for EcR and USP of *C. tentans* were cloned and over-expressed in *E. coli* cells. The affinity purified cEcR and cUSP molecules exhibited the expected binding specificity for active EcREs and Ec in vitro. The bacterially produced and purified nuclear hormone receptor proteins were incubated in the presence of Ec with native isolated polytene chromosomes of a stage with a very low titer and minimal chromosomal localization of the endogenous receptors. The exogenously added cEcR accumulated preferentially at chromosome regions which are always slightly decondensed and Ec-responsive while leaving unoccupied those chromosome regions which in vivo decondense and accommodate endogenous EcR under certain physiological conditions only.

THE ASSEMBLY OF THE VARIOUS INTERCELLULAR JUNCTIONS IN INSECT TISSUES

N.J. Lane, Department of Zoology, University of Cambridge, Downing St., Cambridge, England.

The tissues in insects maintain their integrity by the associations between their component cells. Cellular adhaering molecules (CAMs) help to maintain these intercellular contacts and it seems likely that cadherins are initially responsible for adjacent cells coming into alignment. The assembly of the intramembranous junctional components must then follow. This is complicated by the additional necessity for the extracellular moities to establish contact with one another and for the associated cytoskeletal components to make the appropriate links to those transmembrane molecules that are specifically characteristic of the junction. The situation is further complicated by the fact that there are extensive junctional complexes along the lateral borders of cells both in epithelial layers and in other tissues. Thus, more than one junction may be found on any one border and the molecular constituents of these may be interwoven one with another in an intricate fashion. Junctional types comprising these complexes include septate, scalariform, gap, tight and adhaering junctions, with different tissucs exhibiting varying combinations of these. The distinct features of each of them, their differing molecular nature, organization and associated cytoplasmic proteins, makes it the more astonishing that their assembly is so free from error.

05-053

SEPTATE JUNCTIONS AND INTERCELLULAR ADHERING STRUCTURES IN INSECTS.

R. Dallai, P. Lupetti
Dipartimento di Biologia Evolutiva, Università di Siena, Siena, Italia.

Septate junctions (pleated and smooth types) are the commonest models of junctions present between insect epithelial cells (Lane et al 1994). Midguts of the grasshopper *Pezotettix* and of *Tenebrio* mature larvae prepared by the quick-freeze, deep-etching technique revealed bundles of actin filaments and microtubules in close vicinity of the plasma membrane at the junctional level. A network of strands connects with one another microfilament bundles descending from microvilli. Many of these strands have the same diameter and repeat of actin filaments; some others have a thinner section and no repeat. In the collembolan *Isotomurus* the region beneath microvilli shows a conspicuous filamentous web which receives the bundles of microfilaments of microvilli and is anchored to the plasma membrane at junctional level (Dallai et al. 1993). Quick-freeze, deep-etching microscopy allowed to visualize two classes of filaments in the web: one is in continuity with the microfilaments of the bundles; a second type of filaments thinner than actin filaments, takes contact with the plasma membrane.

STRUCTURAL AND GENETIC ANALYSIS OF DUCTIN IN DROSOPHILA AND CRUSTACEA; A COMPONENT OF THE GAP JUNCTIONS AND VACUOLAR H⁺-ATPase

Malcolm E. Finbow, Beatson Institute for Cancer Research, Gartscube Estate, Bearsden, Glasgow, SCOTLAND, G61 1BD

Ductin is the highest conserved polytopic membrane protein yet known having 80% identity between fungi and *Drosophila*. It forms the site of proton translocation in the vacuolar H⁺-ATPase (V-ATPase) which is the primary proton pump of endomembranes and the plasma membrane of some cell types, most notably certain epithelial cells of the insect midgut and malpighian tubules. In addition, in metazoan animals, ductin is the structural subunit of the connexon of gap junctions. These intercellular specialisations are thought to be the sites of cell-cell communication by allowing the cell-to-cell movement of low molecular weight solutes. Gap junctions containing ductin can be isolated in bulk from the hepatopancreas of the Norway lobster and this, together with a yeast expression system, has allowed a detailed analysis of the structure of ductin and the complex it forms. Ductin forms a four helix bundle in the membrane and six ductin molecules constitute the connexon of the gap junction or the membrane domain of the V-ATPase. The first transmembrane helix lines the central channel of the connexon, whilst the fourth helix is the principal site of proton translocation. In *Drosophila* there is a single gene on chromosome 2R which gives rise to a single product. P-element insertion has been used as a strategy to inactivate the ductin gene (*vha16*). The second intron is a hot spot for P-element insertion indicating a high transcriptional activity of the gene. Homozygous flies containing a tagged P-element die in embryonic stages suggesting loss of the *vha16* gene function is lethal. Heterozygous flies though, appear quite normal.

NUTRITIONAL REQUIREMENTS OF INSECT CELLS CULTURED IN VITRO

J. Mitsuhashi

Faculty of Agriculture, Tokyo University of Agriculture and Technology, Fuchu, Tokyo, Japan
 Since T.D.C. Grace established the first insect cell line in 1962, more than 200 cell lines have been established. Some have recently been used intensively for the production of recombinant proteins by means of the vaculovirus vector system. In order to produce such useful proteins on a commercial basis, it is necessary to develop culture media which support large-scale insect cell cultures. Elucidation of the nutritional requirements of insect cells will aid the development of effective culture media.

In, general, insect cell culture media consist of inorganic salts, sugars, amino acids, vitamins and some growth promoting substances. Insect cells are known to tolerate a wide range of pH and osmotic pressure. NaCl is not essential, and many cell lines can grow in media of various inorganic compositions. As energy source, glucose alone is usually sufficient. The amino acids Arg, Cys, Glu, His, I-leu, Leu, Lys, Met, Phe, Pro, Ser, Thr, Try, Tyr, and Val are essential for most insect cell lines, while the only vitamins required are thiamine, riboflavin, pantothenate and niacin. Many insect cell lines require a growth promoting substance(s) such as fetal bovine serum for their growth, while some can grow in serum-free media.

05-058

THE STRUCTURAL CHANGES OF THE MALE REPRODUCTIVE ORGANS DURING THE REPRODUCTIVE DIAPAUSE AND ITS TERMINATION IN *BRUCHIDIUS ATROLINEATUS* (PIC) COLEOPTERA BRUCHIDAE.J. Huignard, I.A. Glitho¹, A. Lenga

Institut de Recherche sur la biologie de l'insecte (URA CNRS 1298), Université de Tours, France. ¹ Laboratoire de Biologie, Université du Bénin, Lomé, Togo.

The secretions of the male accessory glands play an important role in bruchid reproduction as demonstrated the study of the male reproductive diapause. These glands were non functional during diapause and the first phase of the diapause termination was the accumulation of secretions in the lumen of the gland. In the tropical bruchid, *Bruchidius atrolineatus*, the diapause was induced during post-embryonic development and its intensity depended on the conditions of induction. The diapause intensity was high when diapause was induced in conditions of 23:16°C 12-12h, 13:11h LD, 20-30% rh. There was no spermatogenesis in the tests and the secretory activity of the male accessory glandular cells was limited as long as the males remained in these climatic conditions. The diapause terminated only when the beetles were exposed to shorter photoperiod (11:13h LD), higher humidity (70-80% rh) and to the presence of host plant cues. The diapause intensity was low when diapause was induced in conditions of 40:25°C 12:12h 13:11h LD, 20-30% rh. The secretory activity of the cells of the accessory glands progressively increased and diapause spontaneously terminated when the secretions accumulated in the lumen of the glands. During this phase of diapause termination, the males exhibited a sexual behaviour and deposited during mating a spermatophore in the bursa copulatrix of the females.

INSECT CELL CULTURES: RETROSPECT AND PROSPECT.

K. Maramorosch

Entomology Department, Cook College, Rutgers-The State University, New Brunswick, NJ USA

A brief account of the early pioneering work on insect cell and tissue culture will be presented, starting with Goldschmidt's 1915 attempts to maintain silkworm sperm in vitro. The successful cultivation of viruses in insect cells by Trager and improvements of culture media by him and Silver and Wyatt, leading to the first cell lines by Gao in China and Grace in Australia will be highlighted. Applications of insect cell cultures in genetics, toxicology and biological control of vectors and pests will be described. Current biotechnology applications, including vaccine and drug production, development of cost-effective media and of chemically defined media will be presented.

Predictions for the future will be based on expected solving of several technical problems and on cost-effective large scale industrial production methods. The next decades will most likely witness a large increase in biotechnological applications of cultured insect cells. Novel biotechnological strategies including recombinant DNA and insect cell fusion technology hold considerable promise for the future. It is also conceivable that cost-effective large scale insect cell production will be used to supplement traditional sources of animal and human nutrition.

05-059

PHYSIOLOGICAL ROLES OF THE DROSOPHILA SEX-PEPTIDE: A PEPTIDE PHEROMONE OF THE MALE ACCESSORY GLAND

E. Kubli, I. Fleischmann, M. Soller, P. Saudan, Y. Choffat, T. Schmidt, T. Aigai¹

Zoological Institute, University of Zürich-Irchel, Winterthurerstrasse 190, CH-8057 Zürich, Switzerland - ¹ Department of Biology, Tokyo Metropolitan University, Tokyo 173, Japan

Mating provokes two well defined reactions in the female of *Drosophila* and many other insects: receptivity is reduced and production of eggs increased. In *D. melanogaster*, products of the male reproductive system transferred to the female during copulation, are a primary cause for these effects. Sex-peptide (SP), a peptide of 36aa, plays a major role in the induction of the two post-mating responses. SP is sufficient to elicit the two reactions, but it is not known whether it is also necessary.

Injection of synthetic SP, or ectopic expression in a virgin female, elicit the post-mating responses, suggesting that the SP finds its target(s) via hemolymph. A single kind of target molecule might be responsible for both reactions, however, more than one target tissue is involved.

After a normal mating the two post-mating responses last 7-9 days. In contrast, injection of physiological amounts of SP elicit the reactions for about 1 day. Males which do not transfer sperm, but normal amounts of accessory gland substances, induce egg-laying for about 2 days. Thus, sperm seems to play a role in the persistence of the two reactions. Transgenic flies containing a *yp1* enhancer fused to the SP gene express SP constitutively in the fat body of the adult female and secrete it into the hemolymph. These females permanently lay eggs at the high rate of mated females and show reduced receptivity. These results suggest, that SP is sufficient to elicit the two post-mating responses and that sperm might function as a "stabilizer" for the sex-peptide.

05-060

CONTROL OF SPERM DIMORPHISM IN LEPIDOPTERA

M. Friedländer

Department of Life Sciences, Ben Gurion University of the Negev, Beer Sheva 84105, Israel.

Lepidopteran spermatogenesis is dichotomous and consists of (a) regular eupyrene spermatogenesis leading to the generalized type of insect spermatozoa and (b) irregular apyrene spermatogenesis leading to anucleate spermatozoa. Both kinds of spermatozoa reach the spermatheca but only the eupyrene one fertilizes the eggs. Both types of sperm derive from the same kind of bipotential early primary spermatocytes which differentiate into either eupyrene or apyrene cells. Under non-experimental conditions, the timetable of the dichotomous spermatogenesis is very strict and correlated with the status of ontogenetic development of the individual, and characteristic for a given species. Usually, eupyrene spermatogenesis begins in the larva and stops in the pupa while apyrene spermatogenesis begins just either before or after pupation, according to the species, and continues in the imago. The switchover of spermatocyte commitment is regulated by a haemolymph factor becoming active close to pupation. Spermatogenesis is a discontinuous process punctuated by predetermined stations. Progress from one station to the next is under hormonal control as shown experimentally by (a) transplantations and extirpations of endocrine glands and testes, (b) ligatures, (c) cultures of testes, and (d) treatments by a non-ecdysteroidal ecdysone-agonist, 20-hydroxyecdysone, juvenile hormone, and juvenoids.

Fluctuations of the endocrine balance control the progress of meiosis and sperm differentiation, the stoppage and renewal of spermatogenesis related to diapause, and the shift of spermatogenesis commitment from eupyrene to apyrene development.

05-062

INITIATORIN, A SERINE-ENDOPEPTIDASE AS INDUCER OF SPERM MATURATION OF *BOMBYX MORI* (L.) (LEPIDOPTERA: BOMBYCIDAE)

M. Osanai

Department of Biology, Faculty of Science, Kanazawa University, Kanazawa, Japan

Like other Lepidoptera, *Bombyx mori* produces two types of spermatozoa, denucleated apyrene sperm and nucleated eupyrene sperm that fertilize eggs. These two types of spermatozoa accumulate in the vesicula seminalis without motility. In this organ, apyrene sperm are separated, while 256 eupyrene sperm are packed in the cyst as a bundle. Initiatorin which is a serine-type endopeptidase with 30KDa secreted from the male glandula prostatica acts as the apyrene sperm-activating factor as well as eupyrene sperm bundle-dissociating factor in the spermatophore of females. These two physiological functions of initiatorin were confirmed by the purified specimen obtained using an affinity-chromatography with a column fixed with its inhibitor, p-aminobenzamidine, as a legend. This enzyme has more two capacities to initiate the arginine degradation cascade, an energy-yielding system for sperm maturation by hydrolyzing arginine-rich proteins and to activate the zymogen of an arginine-carboxypeptidase. These reactions for sperm maturation occur in the spermatophore of *Bombyx* silkworm: namely, this organ acts as a reactor of various metabolic reactions for sperm maturation. Trypsin used as a model of initiatorin induced the acquisition of motility of eupyrene sperm of Orthoptera as well as that of apyrene sperm of Lepidoptera. Heterogeneous cross-reaction of immotile apyrene sperm in the vesicula seminalis and the prostatic secretion between two different lepidopteran species caused motility of apyrene spermatozoa.

CIRCADIAN RHYTHM OF SPERM RELEASE FROM TESTIS IN MOTH: ULTRASTRUCTURAL STUDY

J. Giebertowicz, F. Weyda¹Department of Entomology, Oregon State University, Corvallis, OR USA - ¹Institute of Entomology, Czech Academy of Science, Ceske Budejovice, Czech Republic

In insects, mature bundles of elongated spermatozoa leave the testes prior to the reproductive stage. Release of sperm bundles from testis in moths is rhythmic and controlled by a circadian clock which is located in testis-vas deferens complex. Sperm bundles are released from the fused testis into the paired upper vasa deferentia (UVD), then transferred into the seminal vesicles in a two-step rhythm controlled by light-dark cycles (LD). In LD, 16:8, sperm bundles are released from the testis only during the 4 h release gate in the evening, remain in the UVD overnight and are transferred to seminal vesicles in the morning. Rhythmic release of sperm was studied in detail in the gypsy moth, *Lymantria dispar*, using Scanning and Transmission Electron Microscopy. To be released from the testis, sperm bundles must penetrate through the basilar membrane - a layer of specialized epithelial cells separating testis follicles from the UVD lumen. Through most of the day, sperm bundles remain in contact with the testis side of basilar membrane but no penetration of bundles occurs. Approximately 3 h before sperm is first seen in the UVD, sperm bundles, still enclosed in cyst cells, start to penetrate between the cells of basilar membrane. Soon thereafter, sperm bundles dissociate from cyst cells and rapidly translocate into the UVD lumen. Subsequently, cyst cells become fragmented and degenerate.

HISTOPHYSIOLOGY OF MALE ACCESSORY GLANDS OF *DYSDERCUS KOENIGII* F. SEQUENTIAL TO ITS DEVELOPMENTS.S. Sehgal, K.K. Gupta¹Department of Zoology, University of Delhi, Delhi-7. ¹Department of Zoology Deshbandhu College (University of Delhi), Kalkaji, New Delhi-19 India.

The male accessory glands of *Dysdercus koenigii* develop as terminal evaginations of vasa deferentia in early nymphal instars. Each evagination elongates and ultimately thrown into several loops. Histologically, in a newly emerged adult the gland consists of tall columnar epithelial cells that fill the interior of tubule completely. Subsequently a transition of these cells from columnar to cuboidal results in formation of a spacious lumen which later on get filled with some secretions. The secretory activity commences after 24 hr of emergence. The secretions are completely transferred to female during mating. Histochemical studies have indicated an age related difference in the distribution and localization of proteins, lipids, glycogen and nucleic acids within the glandular epithelium and in the secretions. SDS PAGE electrophoresis of the accessory glands of sexually mature male resolved 35 protein bands accounting both structural and secretory proteins. Specific staining with Sudan black B and PAS reagent indicated lipoprotein and glycoprotein nature of a few protein bands. Secretory proteins were mainly of low molecular weight ranging from 14200-29000, which showed variations during development, sexual maturation and mating in the adult.

ALTERATION OF SPERM PROTEINS BY *WOLBACHIA*: A MOLECULAR MODEL FOR CYTOPLASMIC INCOMPATIBILITY
T. L. Karr

Organismal Biology and Anatomy, University of Chicago, Chicago, IL

In *Drosophila simulans* as in many other insect species, a unique form of male sterility known as cytoplasmic incompatibility (CI) is mediated by an endocellular bacterium, *Wolbachia*. This bacterium reduces or abolishes the ability of males to father offspring with uninfected females. From the perspective of *Wolbachia*, CI effectively spreads and maintains the bacteria by preventing the production of uninfected host offspring whenever the male parent is infected. *Wolbachia* readily cross from the ovariole into developing ova, resulting in nearly 100% maternal transmission. By contrast, the exclusion of cytoplasm from the developing sperm usually results in the complete absence of *Wolbachia* in mature sperm. Accordingly, CI cannot be due to sperm-borne *Wolbachia*, and therefore the bacterium must have exerted its influence earlier during spermatogenesis.

Sperm from males infected with *Wolbachia* contain reduced and/or altered protein profiles. Anti-*Wolbachia* monoclonal antibodies were found to recognize cellular host proteins suggesting that *Wolbachia* exert their influence by reducing the levels of specific proteins in the mature sperm. This hypothesis has been confirmed by 2D gel electrophoresis of sperm from infected and uninfected males. Two major and two minor regions have been identified on 2D gels. The two major regions occur in the 70-90 kilodalton range. These proteins are immunologically related to Hsp90 and Hsp70 family as confirmed by immunoblots using anti-hsp90 and anti-hsp70 antibodies. Hsp90/hsp70 have been implicated in numerous signal transduction processes suggesting a model- where *Wolbachia* remove specific isoforms of hsp90 necessary for proper egg activation.

IS THERE A SINGLE Na^+/K^+ -ATPASE α -SUBUNIT IN INSECTS?

A. M. Emery^{1,2,3}, P. F. Billingsley^{1,3}, P. D. Ready², M. B. A. Djamgoz¹

- 1 Dept. of Biology, Imperial College, Prince Consort Rd, London, SW7 2BB, UK - 2 Molecular Systematics Division, Dept. of Entomology, The Natural History Museum, Cromwell Rd., London SW7 2AZ, UK - 3 present address Dept. of Zoology, University of Aberdeen, Tillydrone Ave., Aberdeen, AB9 2TN, UK

The Na^+/K^+ -ATPase (sodium/potassium pump) translocates sodium and potassium ions across the plasma membrane of animal cells. The enzyme is widespread in vertebrate cells where the electrochemical gradients generated by at least three different isoforms are essential for many secondary transport processes, as well as renal and neuronal functions. In insects, the sodium/potassium pump may be more restricted, especially among the Lepidoptera, where the enzyme is apparently absent from all but nerve tissue.

Multiple molecular forms of the sodium/potassium pump α -subunit can be distinguished as doublets in SDS-PAGE. Our results with *Anopheles stephensi* and *Stomoxys calcitrans* are consistent with a single molecular form of the α -subunit which is found predominantly in the head, with lesser concentrations in the midgut, Malpighian tubules and thorax. Biochemical analysis of the midgut and head enzyme using the specific cardiotonic steroid, ouabain, indicate no apparent differences between the two tissues.

Using a PCR approach we have compared partial sequences of insect Na^+/K^+ -ATPases, and concluded there is likely to be a single gene for the α -subunit of this enzyme in Diptera and Lepidoptera, whereas vertebrates have at least three distinct genes (Emery *et al.* 1995). The insect form is apparently distinct from any one of the vertebrate isoform classes.

Emery *et al.* (1995). *Insect Molecular Biology* 4:179-192

05-065

MALE SPECIFIC PROTEIN IN THE HEMOLYMPH OF GREATER WAX MOTH, *GALLERIA MELLONELLA* L.

Hak R. Kim, Haeng-Yeun Lee, Yong-Ho Lee, Sang-Dae Lee.

Department of Biology, Korea University, Seoul, Korea

Male specific protein(MSP) was identified and purified from adult male hemolymph of *Galleria mellonella* L. by gel electrophoresis and anion exchange chromatography. Its physiochemical property including molecular weight, amino acid composition and carbohydrate were also investigated. The presence of MSP in various organs was confirmed during developmental stages by western blotting and immunodiffusion using antibody against it. MSP was present in fat body as well as hemolymph of adult male. MSP is also present in testes of late pupae and adults. Fat body of pupae and adults was *in vitro* tissue-cultured in culture medium including [³⁵S]-methionine. MSP was actively synthesized in fat body of adult male. Function and fate of MSP were also being investigated.

EXPRESSION OF A MIDGUT AMINO ACID TRANSPORT SYSTEM IN *XENOPUS* OOCYTES

V.E. Sacchi and M. Castagna

Istituto di Fisiologia Generale e Chimica Biologica, Università di Milano, Italia

In the last years the functional expression cloning strategy led to discover the structure of many proteins involved in membrane transport processes. The first step of this experimental approach is the expression of a new protein after injection of exogen mRNA in *Xenopus* oocytes. In this study, mRNA purified from midguts of *Philosamia cynthia* larvae was injected into *Xenopus laevis* oocytes and the increased leucine uptake was interpreted as expression of a new transport system whose features closely resemble those of the amino acid transport system present in the tissues where mRNA was purified from. Amino acid transport in the midgut of several species of lepidopteran larvae involves a new class of amino acid cotransporters with broad specificity for the driver cation which can be potassium, sodium and in some case lithium. Sodium affinity for the transporter is about 18 times that of potassium, whereas, at saturating cation concentrations, leucine transport rate was 2.5 times higher with potassium. Sodium activation curve of leucine uptake was sigmoidal in control oocytes and hyperbolic in mRNA-injected oocytes. The difference between the two curves gives the sodium activation of the newly expressed leucine transport. The mean K_{50} was 0.4 ± 0.24 mM, a value near to that found in *P. cynthia* larvae and about 50 times lower than the K_{50} value measured in control oocytes. mRNA from *P. cynthia* midgut was fractionated on sucrose density gradient and after injection of fractions, two pools could be identified which caused an increase of leucine uptake.

05-068

UNUSUAL HIGH CONCENTRATION OF FREE GLYCINE IN THE MIDGUT CONTENT OF THE SILKWORM, *BOMBYX MORI*, AND OTHER LEPIDOPTERAN LARVAE

K. Konno, C. Hirayama, H. Shinbo

National Institute of Sericultural and Entomological Science
1-2 Ohwashi, Tsukuba Ibaraki 305, Japan

In the course of investigating the digestion and the absorption of dietary protein by the silkworm, *Bombyx mori*, reared on an artificial diet, we found the existence of an unusually higher concentration of free glycine in the midgut content compared with other amino acids. To test whether this free glycine is from diet or from the silkworm itself, silkworm larvae were fed a diet without a protein source for 1 day and the free amino acids in the midgut content were then analyzed. Unexpectedly, the concentration of free glycine in the midgut content was still high (8.98 μ moles/g midgut content). In contrast, the concentrations of other amino acids were very low, and none of them exceeded 1/20 that of glycine. The concentration of glycine was high in the anterior half of the midgut and it decreased toward the posterior region. Free glycine was virtually undetected in the feces. A similar phenomenon, as in the silkworm, was observed in the sweet potato hornworm, *Agrius convolvuli*, but not in the rice armyworm, *Pseudaletia separata*. We also found that an unusual high concentration of free glycine exist in the digestive juice of *Bombyx mori*.

These results suggest that free glycine is secreted into the intestinal lumen for some biological purpose.

05-070

JUVENILE HORMONE AND JUVENILE HORMONE ACID BIOSYNTHESIS BY THE CORPORA ALLATA OF ADULT FEMALE AND MALE LOREYI LEAFWORM, *MYTHIMNA LOREYI* DUPONCHEL (LEPIDOPTERA: NOCTUIDAE)

R. Kou · C. Y. Chang, M. P. Tu
Institute of Zoology, Academia Sinica, Taipei, Taiwan,
Republic of China

In *Mythimna loreyi*, the *in vitro* releases of juvenile hormone II (JH II) and juvenile hormone III (JH III) by adult female corpora allata (CA) were age-dependent, which peaked at day 4 (1.19 and 2.92 pmol/ 4h/ pair CA for JH II and JH III, respectively) and day 9 of adulthood (2.43 and 4.95 pmol / 4h/ pair CA for JH II and JH III, respectively). The *in vitro* releases of juvenile hormone acid I (JHA I), Iso-juvenile hormone acid II (Iso-JHA II) and juvenile hormone acid III (JHA III) by adult male CA were also age-dependent; the trends of JHA I and Iso-JHA II were similar, which peaked at day 3 (11.56 and 9.64 X 10² pmol/ 24 h/ pair CA for JHA I and Iso-JHA II, respectively) and day 10 (6.46 and 10.71 X 10² pmol/ 24 h/ pair CA for JHA I and Iso-JHA II, respectively); for JHA III, the release rate peaked at day 4 (18.42 X 10² pmol/ 24 h/ pair CA) and day 10 (16.16 X 10² pmol/ 24 h/ pair CA); the release rate of juvenile hormone acid II (JHA II) was constantly low from any age group. Male CA from different time intervals of a 24 h photoperiod showed different abilities to release JHAs.

05-069

EFFECT OF DIMBOA ON NUTRITIONAL INDICES, DIGESTIVE PROTEASES AND DETOXIFICATION ENZYMES OF *SESAMIA NONAGRIOIDES* (LEPIDOPTERA: NOCTUIDAE) LARVAE

F. Ortego, M. Ruiz, P. Castañera
Centro de Investigaciones Biológicas, CSIC, Madrid, Spain

The hydroxamic acid 2,4-dihydroxy-7-methoxy-1,4-benzoxazin-3-one (DIMBOA) was assessed for its effect on the digestive physiology of larvae of the stalk corn borer *Sesamia nonagrioides* Lef. Nutritional indices and enzymatic activities were determined for larvae feeding on a DIMBOA-containing diet for the first two days of the third instar (short-term assays), for the full third instar (middle-term assays), and from neonates to third instar (long-term assays). In long-term feeding assays, DIMBOA reduced the relative growth rate (RGR), and the efficiency of conversion of ingested food (ECI), without affecting the relative consumption rate (RCR). However, DIMBOA had no effect on RGR, RCR, and ECI in short- and middle-term feeding assays .

Trypsin, chymotrypsin, elastase, carboxypeptidase A and B, and microsomal oxidase activities were significantly increased by DIMBOA in middle term-assays, whereas esterase activity was reduced. Elastase in short-term assays and chymotrypsin, elastase and microsomal oxidase activities in long-term assays were also increased. Moreover, DIMBOA inhibited *in vitro* the activities of both carboxypeptidases, aminopeptidase, glutathione S-transferase and esterase, but it had no effect on the endoproteases.

The implications of the altered levels of proteases and detoxification enzyme activities on the digestive physiology of larvae feeding on DIMBOA-containing diets are discussed.

05-071

HEAT SHOCK COGNATE PROTEINS AND DEGRADATION OF JUVENILE HORMONE ESTERASE IN *MANDUCA SEXTA* (LEPIDOPTERA: SPHINGIDAE).

B.C. Bonning
Department of Entomology, Iowa State University, Ames, IA, USA

A heat shock cognate protein (Hsc) is involved in degradation of hemolymph proteins such as juvenile hormone esterase (JHE), in the pericardial cells of the tobacco hornworm, *Manduca sexta*. Efficient removal of JHE is effected by receptor-mediated endocytosis by the pericardial cell complex and is essential for larval development. Endocytic vesicles fuse with the *trans*-Golgi network where proteins are sorted for return to the cell surface, or for degradation in lysosomes. Immunohistochemical studies suggest that the Hsc is in the *trans*-Golgi network or the prelysosomal compartment of the pericardial cells. This Hsc appears to be unique in size and immunological cross-reactivity relative to other heat shock protein families. Immunoprecipitation experiments indicate that the binding of Hsc to JHE is reduced by mutagenesis of specific residues in the putative lysosome-targeting sequence of JHE. We hypothesize that the Hsc acts as a chaperone of JHE from the *trans*-Golgi network into the prelysosomal compartment for transfer to lysosomes for degradation. This is the first report of Hsc involvement in degradation of an extracellular protein.

05-072

EXTRACTION AND CHARACTERIZATION OF THE DARK COLOR INDUCING NEUROHORMONE FROM THE CORPORA CARDIACA OF *LOCUSTA MIGRATORIA*.Y. Yerushalmi¹, S. Tanaka², Y. Milner³, M.P. Pener¹.

¹ Department of Cell and Animal Biology, The Hebrew University, Jerusalem, Israel - ² Department of Insect Physiology and Behavior, National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan - ³ Department of Biological Chemistry, The Hebrew University, Jerusalem, Israel.

We extracted and purified a dark color-inducing neurohormone (DCIN) from the corpora cardiaca (CC) of a normal strain of *Locusta migratoria* by employing a novel bioassay based on an albino strain of this species in which the DCIN is absent or physiologically non-functional. Dried methanol extracts of the CC of the normal strain, resuspended and injected in olive oil, induced dose-dependent darkening of the albino hoppers. Injections in aqueous media were ineffective. Methanol extracts of normal CC, submitted to gel filtration on Sephadex LH-20 column, followed by reverse phase HPLC with acetonitrile gradient, yielded a single active fraction. Mass spectrogram of this active fraction showed a single peak of 3,752 dalton. Preliminary sequence analysis revealed the first 16 amino acids of the DCIN. The latter result, and also those of some further experiments, showed that the DCIN is distinctly different from any other known dark color promoting insect neurohormone, including the MRCH (=PBAN).

This research was partially supported by the Israel Science Foundation administrated by the Israel Academy of Science and Humanities.

SOURCE OF THE LIPIDS IN MOSQUITO OOCYTES.

R. Ziegler, H.A. Bluestein and J. Poole. Department of Biochemistry, University of Arizona, Tucson, AZ 85721, USA

Mosquito eggs, like all animal eggs, contain large amounts of lipids. The lipids are needed to form membranes and to supply energy to the developing embryo.

Mature oocytes of the mosquito, *Aedes aegypti*, contain on a weight basis about 30% lipids. The lipids could be synthesized in the ovary, or they could be transported to the oocyte from fat body or from the gut after a blood meal. Experiments with radiolabeled water demonstrated that ovaries incorporate a small amount of label into lipids, mostly into phospholipids and triacylglycerol. More than 90% of this label is found in glycerol and less than 10% is incorporated into fatty acids, indicating that lipids from other sources are transported to the oocytes and taken up.

Insects transport lipids by lipophorin, their major hemolymph lipoprotein. Radiolabeled fatty acids presented by lipophorin as acylglycerol or as free fatty acids are readily taken up by mosquito ovaries in vitro.

Acylglycerols can only be taken up if they are first hydrolyzed by a lipase to form free fatty acids and glycerol. In homogenates of ovaries lipase activity was found. The subcellular localization of the lipase will be examined.

CRYO-ELECTRON MICROSCOPY OF A HIGH DENSITY LIPOPHORIN FROM THE HEMOLYMPH OF THE HAWKMOTH *MANDUCA SEXTA*Rik van Antwerpen¹ and John C. Gilkey².

¹ Department of Biochemistry and Center for Insect Science, and ² Department of Pharmacology, University of Arizona, Tucson, AZ USA

In the hemolymph of the hawkmoth *Manduca sexta*, lipids are transported by a high density lipoprotein, called high density lipophorin (HDLp). We have analyzed the structure of this lipoprotein, using cryo-electron microscopy and computer-assisted image processing. HDLp was studied in a frozen-hydrated condition, without chemical fixation or any form of staining. As the contrast of cryo-electron micrographs is directly related to the distribution of mass density within the actual preparation, distinct high density structures in our micrographs are indicated to represent apoprotein domains within the lipoprotein particle. Different projections of HDLp with three or four separate, globular domains of high density were recognized, which suggests that the observed domains may be organized at tetrahedral positions relative to each other. This organization is very different from the organization of high density in cryo-electron micrographs of the human low density serum lipoprotein (LDL). The present results demonstrate that cryo-electron microscopy may visualize structural properties of lipoprotein particles that, to date, can not be detected by any other means.

This work was supported by grant GM 50551 from The National Institutes of Health.

ENZYMATIC ANALYSES OF URICOTELY IN THE MOSQUITO *Aedes Aegypti* (DIPTERA: CULICIDAE)P. von Dungen & H. Briegel
Zoologisches Institut der Universität Zürich, Zürich / Switzerland

When feeding on blood, female mosquitoes ingest protein in excess of the requirements for oogenesis. The surplus of nitrogen is removed from the metabolism by the synthesis of uric acid which is catalized by xanthin dehydrogenase (XDH). XDH activity profiles were established for sugarfed and for bloodfed females of *Aedes aegypti*. After discharge of the meconium, XDH activity gradually diminished in females maintained on sucrose. After bloodmeal however, XDH activity increased substantially, and it returned to pre-bloodmeal levels upon termination of digestion.

In females given measured volumes of blood by enema, XDH activity was proportional to the protein input and urate excretion as well. The primary site of XDH activity is the fatbody. The activity profiles have also been explored in ageing females and in comparison to the proteolytic enzymes within the midgut after blood meal.

Considerable XDH activities were observed in fourth instar larvae and teneral pupae as well. This result was surprising because in water-living instars or insect species uricotelous has not been recorded before. The possibility of storage excretion of urate in some form by the aquatic mosquito larvae remains to be investigated.

PROLINE IS A WIDESPREAD FUEL FOR FLIGHT IN BEETLES

G. Gäde, L. Auerswald

Zoology Department, University of Cape Town, Rondebosch, Republic of South Africa

Flying insects utilize various substrates to power the flight muscles: carbohydrates are known to be the predominant or exclusive fuel for flies and bees, whereas locusts and butterflies oxidize lipids during long-distance flights. The tsetse fly, but also the Colorado potato beetle are well-known examples of gaining energy for flight by partially oxidizing the amino acid proline. But is this phenomenon restricted to a few special cases or is this type of energy metabolism much more ubiquitous than previously thought?

Detailed analysis of maximal activities of key enzymes of energy metabolism in the flight muscles, of oxidation of various substrates by isolated flight muscle mitochondria and of changes of concentration of metabolites during flight in haemolymph and flight muscles have shown that proline is an important fuel for flight in scarabaeid (*Pachnoda sinuata*, *Onitis pecuarius*, *Scarabaeus deludens*, *Melolontha melolontha*, *Trichostetha albopicta*, *Trichostetha fascicularis*) and meloid beetles (*DeCAPotoma lunata*). However, no proline was detected in the haemolymph of buprestid beetles.

HAEMOLYMPH SUGARS AND THE CONTROL OF THE PROVENTRICULUS IN THE HONEY BEE *APIS MELLIFERA*

J. Overath, F. Roces

Theodor-Boveri-Institut, Lehrstuhl für Verhaltensphysiologie und Soziobiologie der Universität, Würzburg, Germany

In insects feeding on liquid food, both haemolymph osmolarity as well as titres of specific nutrients have been observed to play a role in modulating crop-emptying rates. In honey bees, haemolymph osmolarity has been suggested as the main factor affecting the flow of sugar solution from the social crop to the gut via the proventriculus. We present evidence indicating that the level of trehalose in the haemolymph controls crop-emptying rates through the proventriculus in the honey bee. Bees were trained to collect a given amount of sugar solution of different concentration. After voluntary feeding, they were caged for different periods and then dissected, in order to determine crop content, rectal pouch content and haemolymph sugars. In order to distinguish between haemolymph osmolarity and nutrient titres as factors controlling the activity of the proventriculus, groups of trained foragers were injected with nutritive carbohydrates such as trehalose and glucose, and control groups with non-nutritive carbohydrates (fucose, sorbose), which produce a similar increase in haemolymph osmolarity but cannot be metabolised by bees. Measurements of crop-emptying rates, urine production, metabolic expenditure and sugar levels in the haemolymph indicated that the sugar flow through the proventriculus rather than the flow of solution is controlled, and that an increase in trehalose levels in the haemolymph, irrespective of the concomitant increase in osmolarity, directly inhibited the activity of the proventriculus.

05-078

LIPID METABOLISM IN *Rhodnius prolixus* MIDGUT (HEMIPTERA)

G.C.Atella; HSL Coelho; M.A.B.C.F.Arruda; K.C.Gondim and H.Masuda
Departamento de Bioquímica Médica, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brasil.

In *Rhodnius prolixus* during the period of oogenesis the lipophorin transfers phospholipids to the developing oocytes and is reloaded with more phospholipids at the fat body or at the midgut. The interplay among this tissues depend on the physiological state of insect. During the period of intensive dietary absorption lipophorin takes up phospholipids preferentially at the midgut and later on, when blood digestion slow down, at the fat body. In this work we studied incorporation of free fatty acids by midgut of *Rhodnius*. When radioactive C¹⁴-Oleic acid was injected into hemocel of females the radioactivity was recovered associated with lipophorin. Ten minutes after injection the radioactivity disappeared from hemolymph, and was recovered mainly at the midgut. The capacity of midgut to incorporate C¹⁴-Oleic acid increased until the tenth day after feeding. However, the midgut ability to transfer lipids to lipophorin, decreases from day one onward. The C¹⁴-Oleic acid incorporated by the midgut was distributed among phospholipids (60%) and neutral lipids (40%). The fate of C¹⁴-lipids synthesized by the midgut was followed and it was observed that diacylglycerol is the major lipid released to lipophorin particles. While the C¹⁴-phospholipids synthesized by the midgut are not transferred to lipophorin but it is probably used for membrane synthesis. C¹⁴-Phospholipids were found associated with the luminal content of *Rhodnius*.

PURIFICATION AND PARTIAL CHARACTERIZATION OF A LUTEIN-BINDING PROTEIN FROM THE MIDGUT OF THE SILKWORM *Bombyx mori*

Z.E. Jouni and M.A. Wells

Biochemistry Department and Center for Insect Science
University of Arizona, Tucson, AZ 85721

A carotenoid-binding protein was purified from fifth instar larval midgut of *Bombyx mori* by a combination of ammonium sulfate fractionation and three chromatographic procedures: gel filtration, chromatofocusing, and anion exchange chromatography. The protein has a pI of 5.4 and an apparent molecular mass of 35,000 Da, as determined by a linear gradient SDS PAGE. The carotenoid-protein complex is water soluble and more stable than the carotenoid or protein alone. The carotenoid moiety was identified by thin layer chromatography, light absorption spectroscopy, and HPLC as *all-trans*-lutein. Lutein is specifically and stoichiometrically bound to the protein, with a ratio of three mols of carotenoid per mol of protein. Binding of lutein (absorption maximum in hexane at 454 nm) to the apoprotein results in a marked red spectral shift of about 38 nm, giving rise to absorption maxima at 432 nm, 462 nm and 492 nm in 20 mM Tris-HCl, pH 7.0. The carotenoid-protein complex is characterized by fine spectral structure indicating that lutein is in a relatively rigid environment. This protein is distributed in equal amounts throughout the midgut and in all developmental stages of the larval *B. mori*. Supported by NIH grant 50008.

IN VIVO PHYSIOLOGICAL STUDIES OF LIPID TRANSFER PARTICLE IN *BOMBYX MORI* USING ANTIBODIES

Kozo Tsuchida and Hideaki Maekawa

Division of Radiological Protection, National Institute of Health,
Tokyo 162, Japan

Lipid transfer particle (LTP) is a high molecular weight complex of three apoproteins and lipids. *In vitro* studies showed that LTP transfers lipids between lipophorins, from fat body to lipophorin and from lipophorin to the developing oocyte, but the physiological role of LTP in lipid transfer reactions in insect hemolymph is not yet understood. I have studied the functional properties of *Bombyx mori* LTP *in vivo*, using antibodies.

LTP and lipophorin concentrations in hemolymph from 4th instar larvae to adult were determined by immunodiffusion. The total amount of LTP in hemolymph was rapidly increased from 5th instar day 0 to day 4, then dropped gradually at pupation. The protein concentration ratio between LTP and lipophorin was 1:15, all through the 4th and 5th instar larval stages, and 1:25 during the pupal stage. To clarify the physiological role of LTP lipid transfer activity *in vivo*, anti LTP IgG was injected in larvae and pharate adults. In larvae injected with anti-LTP IgG, low density lipophorin (LDLp) was diminished, and only high density lipophorin (HDLp) existed in the hemolymph. In addition LTP was shifted to a higher density fraction than the control. In adults injected with anti-LTP IgG, all lipophorin was observed as LDLp, HDLp was completely diminished or was not produced. On the other hand, control adults injected with preimmune rabbit IgG had two type of different density lipophorin. These results indicated that anti-LTP IgG can block the lipid transfer activity of LTP in hemolymph and suggest that the most important role of LTP is not to transfer lipids between lipophorin particles.

05-081

THE ROLE OF FATTY ACIDS PRODUCED IN SCALE-COVER AND SECRETORY MATERIALS OF FIVE SCALE INSECTS (COCCOIDEA:HOMOPTERA)

M.K. Hamdy

Department of Pest&Plant Protection, National
Research Centre, Dokki, Cairo, Egypt.

The quantity and quality of the fatty acids produced in their scale-covers and secretory materials were investigated using GLC experiments.

The experiments aimed to find out any relationship may differentiate among three diaspidid scales representing the three tribes of family Diaspididae (long scale-cover, circular scale-cover and those puparium scale-cover), as well as two soft-scale insects, one belonging to family Coccidae and the other belonging to the family Margarodidae.

The puparium, *Parlatoria zizyphus* (Lau.) was the richest producer of palmitic (24%), oleic (20%) and palmitoleic (17%). The long-scale, *Lepidosaphes beckii* (Newm.) was the richest producer of arachidic (15.8%) and linolenic (10.5%). The circular, *Aonidiella aurantii* (Mask.) was the richest in myristic (33.4%) followed by palmitic (20%).

The coccid, *Ceroplastes rusci* (L.), however, surpassed all the examined insects in myristic (49%) and lauric (12%), but the margarodid surpassed in the production of capric (39.5%).

ISOFORMS OF *BOMBYX MORI* ECDYSONE RECEPTOR AND THEIR EXPRESSION DURING METAMORPHOSIS

M. Kamimura¹, S. Tomita¹, M. Kiuchi¹ and H. Fujiwara²

¹ National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan - ² Zoological Institute, Faculty of Science, University of Tokyo, Bunkyo-ku, Tokyo, Japan

Using 5'-RACE methods, two different 5' ends of *Bombyx mori* ecdysone receptor homologue (BmEcR) cDNA were obtained. They were different in the A/B region, but same in the downstream of C (DNA binding) region. As BmEcR was indicated to be a single copy gene (Swevers *et al.*, 1995), it is suggested that they are generated by different promoter usage or alternative splicing, like isoforms of *Drosophila melanogaster* EcR (DmEcR). One of these cDNAs was homologous to DmEcR A isoform and another was homologous to B1 isoform, so they were named BmEcR-A and BmEcR-B1, respectively. Both of BmEcR-A and BmEcR-B1 specific probes detected single 6 kb message in the northern analysis, indicating that those mRNAs are about in a same size. Both isoforms were expressed in tissue-specifically at the larval-pupal metamorphosis. During the last larval instar, expression of BmEcR in the wing discs was maximal on the day of wandering, indicating that the expression of BmEcR is prerequisite for the wing discs to respond to the drastic increase of hemolymph ecdysteroid titer.

ECDYSONE AND 20-HYDROXYECDYSONE AFFECT THE SENSITIVITY OF EPIDERMIS TO ECDYSTEROIDS DIFFERENTLY IN THE SILKWORM, *BOMBYX MORI*.

Y. Tanaka and M. Kamimura

National Institute of Sericultural and Entomological Science, Tsukuba Ibaraki 305 JAPAN

In order to explore the different effect of ecdysone and 20-hydroxyecdysone on larval development in the silkworm, *Bombyx mori*, larval epidermis were cultured in Grace's medium and their responses to ecdysteroids were investigated. The epidermis dissected from newly-ecdysed fourth instar larvae responded to 20-hydroxyecdysone ≥ 10 ng/ml by forming new cuticle (apolysis) within 3 days, and the epidermis dissected from the fifth-instar larvae induced by ecdysone responded to almost the same level of 20-hydroxyecdysone *in vitro*. On the other hand, even 50 ng/ml of 20-hydroxyecdysone did not induce apolysis in the epidermis of the larvae induced by 20-hydroxyecdysone. These results suggest that the two ecdysteroids affect the sensitivity of epidermis to ecdysteroids differently and that the fifth-instar larvae induced by 20-hydroxyecdysone died without apolysis because of the decline in the sensitivity of epidermis to ecdysteroids.

05-083

THE ECDYSONE REGULATED PUFFS IN *CERATITIS CAPITATA* SALIVARY GLANDS

A. Gariou-Papalexiou, A. Mintzas and A. Zacharopoulou.

University of Patras, Department of Biology, Division of Genetics, Cell and Developmental Biology, Patras, Greece.

The steroid hormone ecdysone acts as a temporal signal to coordinate tissue specific morphogenetic changes in insects through the activation of a large number of primary and secondary genes. Extensive studies in *Drosophila* have answered several questions concerning the mechanisms of ecdysone response as well as have raised new ones. Given the wide array of ecdysteroids among insects and the differences in their life cycles, parallel studies in other insect species and particularly in those of economic importance, may reveal unique future of hormone regulation, thus establishing the basis for developing species-specific pest control methods. We have undertaken such studies in the Medfly and our data from the cytogenetic analysis of the ecdysone action are presented in this report.

Sequential changes in the puffing activity of *C. capitata* salivary gland chromosomes take place during the late larval and prepupal stages. The most remarkable changes were observed at the jumping stage during which the titer of ecdysone increases in the haemolymph and larvae jump out of the medium in order to pupate. Tissue culture experiments in the presence of ecdysone and inhibitors of protein synthesis, indicated that most of the changes in the puffing activity were due to the ecdysone. A small number of puffs are either suppressed or induced directly by ecdysone while the majority of the ecdysone depended puffs are induced indirectly and required protein synthesis in addition to the hormone.

05-085

INTEGUMENT CHARACTERISTIC TO THE LAST LARVAL STADIUM IN THE SWEET POTATO HORNWORM, *AGRIUS CONVULVULI* (LEPIDOPTERA; SPHINGIDAE)

K. Tateishi, J. Mitsuhashi

Laboratory of Applied Entomology, Faculty of Agriculture, Tokyo University of Agriculture and Technology, Fuchu, Tokyo, Japan

The sweet potato hornworm, *Agrius convulvuli*, pupates after the 5th or the 6th larval stadium. Most of larvae became the 6th stadium by malnourishment after the 3rd stadium. There were many processes on entire surface of the cuticle at immature stadia. The processes disappeared at the last larval stadium. The integument of the 5th stadium larvae was similar to that of the 4th stadium day 2 larvae in its inner morphology. When the integument of the 4th stadium day 1 larvae was cultured in the MGM-450 medium containing 20-hydroxyecdysone, apolysis was induced, but new integument was not formed. However, from the morphological changes of epidermis it was assumed that the change to the last stadium type integument was initiated before day 1 of the penultimate stadium. Cuticular proteins were analysed by native PAGE, and one of cuticular proteins existed up to the 4th stadium proved to disappear at the last stadium.

05-086

STUDIES ON THE MOLECULAR STRUCTURE OF JUVENILE HORMONE AND ITS BIOSYNTHETIC PATHWAY IN THE HOUSEFLY *MUSCA DOMESTICA*.

K.J. Yagi, A. Moribayashi*, S.S. Tobe and N. Agui*.

Department of Zoology, University of Toronto, Toronto, Canada and * Department of Medical Entomology, National Institute of Health, Tokyo, Japan.

The housefly, *Musca domestica* is a nuisance pest in Japan and occurs as both anautogenous and autogenous strains. Egg development in the females is known to be under control of ecdysteroids and is affected by synthetic juvenoids. Our studies investigated the biosynthetic pathway of the juvenile hormone production and its role in oögenesis in the female housefly using the *in vitro* radiochemical assay for juvenile hormone biosynthesis.

Ring glands incubated with [³H]-methyl methionine biosynthesized radiolabelled product that co-chromatographed on TLC with synthetic juvenile hormone bisepoxide (JHB₃) and occurred at a constant rate over a 6 hr incubation period. Since rates of egg development varied between individual female flies, rates of oögenesis were standardized by staging according to the technique of Adams, 1974. Rates of JHB₃ biosynthesis by female ring glands in strains of autogenous (Misaki strain) and anautogenous (Chubo strain) were different during the first gonotrophic cycle. The autogenous strain showed a rapid increase in biosynthesis during the early stage of oögenesis (3-4) followed by a plateau (stage 5-6). A decrease in the rate was seen at stage 7, but was followed by an increase (stage 8-9) to a level above that seen during the previous stage (5-6). The rates of biosynthesis of ring glands from females with mature eggs (stage 10) decreased to zero level. In contrast, the anautogenous strain did not show any further increase during the late vitellogenic stage (8-10).

05-087

PURIFICATION AND CHARACTERIZATION OF JUVENILE HORMONE BINDING PROTEIN FROM CYTOSOL OF THE SILK GLAND OF THE SILKWORM, *BOMBYX MORI*

Keiji Kurata

Department of Insect Physiology and behavior, National Institute of Sericultural and Entomological Science, Tsukuba Ibaraki, Japan

A juvenile hormone binding protein (JHBP) has been isolated from cytosol of silk glands of *Bombyx mori* by ion-exchange chromatography, gel filtration, chromatofocusing and polyacrylamide gel electrophoresis (PAGE). The cytosol was provided by ultrasonic treatment of the silk glands in a 50 mM Tris-HCl buffer containing protease inhibitors, 7.4 pH. The JHBP has a relative molecular mass of 29 kDa, determined by sodium dodecyl sulfate PAGE. Chromatofocusing analysis indicated that the JHBP is an acidic protein with pI 5.8. The protein exhibits a dissociation constant of 1.2×10^{-8} M for Juvenile hormone III.

05-088

JUVENILE HORMONE MEDIATED NEUROENDOCRINE CONTROL OF SEXUAL BEHAVIOUR IN MALE *BLATTELLA GERMANICA* LINN. (BLATTOIDEA ; BLATTELLIDAE)S. C. Pathak¹, Rita Bhandari²

1. - Department of Biological Sciences, Rani Durgavati University, Jabalpur 482001 India

2. - Department of Zoology, Govt. Autonomous Science College, Jabalpur 482001 India

The effects of various components of the neuroendocrine system on the sexual behaviour of male cockroach *Blattella germanica* Linn. were investigated with the help of frontal ganglionectomy, cauterisation of the cerebral neurosecretory cells, chemical inhibition of the corpus allatum and administration of exogenous Juvenile hormone. The results reveal that the sexual behaviour is completely blocked when any of the three components viz. frontal ganglion, cerebral neurosecretory cells or the corpus allatum is removed / inhibited. Administration of exogenous Juvenile hormone brings about resumption of this behaviour, after about 24 hours of such administration.

05-089

IN VIVO* AND *IN VITRO* REGULATION OF THE CORPUS ALLATUM BY BRAIN IN THE HEMIPTERAN *PYRRHOCORIS APTERUSM. Hodkova, T. Okuda¹

Institute of Entomology, Academy of Sciences, C. Budejovice, Czech Republic - 1 Department of Insect Physiology and Behavior, National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan

Surgical interventions to the neuroendocrine system *in situ* indicate that photoperiodic regulation of reproduction in *Pyrrhocoris apterus* is mediated by pars intercerebralis (PI) of the brain. The complexes of brain-suboesophageal ganglion-corpora cardiaca-corpora allatum extirpated from short day (diapause) and long day (non-diapause) females were subjected to extirpation of the PI or transection of nerves from brain to the corpus allatum (CA). Thereafter, the activity of operated and control complexes was measured either by ovarian maturation *in vivo* (after transplantation to diapause or allatectomized females) or by synthetic activity of the CA *in vitro*. It was found that the activity of the CA was inhibited from the PI in both short day and long day complexes but the inhibition induced by short days was stronger. The inhibitory factor acted via both nervous and humoral pathways.

05-090

ALLATOSTATIN CONTAINING GRANULES IN HEMOCYTES OF THE COCKROACH, *DIPLOPTERA PUNCTATA* (Blattaria, Blaberidac)

B. Stay, J. R. Skinner, S. E. Fairbairn

Department of Biological Sciences, University of Iowa, Iowa City, IA 52242 USA

Among the hemocytes in the hemolymph of *Diploptera punctata* is a population with granules that immunoreact with antibodies against a *D. punctata* allatostatin (A-P-S-G-A-Q-R-L-Y-G-F-G-L-NH₂). The allatostatins isolated from this cockroach are a family of neuropeptides that, among other functions, inhibit juvenile hormone synthesis in the cockroach and related insects, e.g., cricket. Allatostatin positive hemocytes vary from 6 to 13 per cent of the hemocytes. Older animals (70 days after adult emergence) have fewer (~2%) than those within a week of adult emergence or in the nymphal stage. These hemocytes exhibit a fine structure consistent with the production and storage of allatostatin immunopositive material. The potential contribution of hemocytes to the regulation of the juvenile hormone synthesis by the corpora allata will be discussed.

05-092

Concentration of cyclic AMP and Activity of cyclic AMP-dependent Protein Kinase in Chestnut Weevil, *Curculio dentipes*

Jin-Soo Ryou, Yoo-Kyung Kim, and Kyung-Ro Lee (Department of Biology, College of Sciences, Kon-Kuk University, Seoul 133-701, Korea)

The concentration of cyclic AMP (cAMP) of whole body and activity of cyclic AMP-dependent protein kinase (PKA) in partial purification were measured in chestnut weevil, *Curculio dentipes* according to the non-overwintering, wintering, and overwintering larvae. cAMP concentration and PKA activity measured by HPLC and Liquid Scintillation Counter, and investigated the correlation of cAMP and PKA

The cAMP concentration were found to be the maximum at the non-overwintering larvae (0.57 μ M/g) and decreased at the wintering larvae (0.14 μ M/g). At the overwintering larvae, it was increased again (0.29 μ M/g). Also, the activity of PKA were showed the highest level at the non-overwintering larvae (2.56 unit/mg) and decreased at the wintering larvae (0.62 unit /mg) in calcium phosphate gel purification step, whereas it increased again at overwintering larvae (2.07 unit/mg).

Therefore, cAMP concentration and PKA activity were shown to be similar aspect. This results were suggested that the accumulation of fat body in non-overwintering larvae appeared to be more closely related to largest ingestion prior to diapause and that cAMP concentration and PKA activity increased with prepare of larval-pupal ecdysis and termination of diapause in overwintering larvae, whereas cAMP and PKA level decreased with fat body degradation at wintering larvae for use of energy source.

05-091

INTRACELLULAR SIGNAL TRANSDUCTION OF PBAN IN THE SILKWORM, *BOMBYX MORI*.

S. Matsumoto, M. Kurihara, and R. Ozawa

Insect Toxicology and Physiology, The Institute of Physical and Chemical Research (RIKEN), Wako-shi, Saitama, 351-01, Japan

Pheromone biosynthesis activating neuropeptide (PBAN) regulates sex pheromone production in a number of lepidopteran species. In *B. mori*, PBAN regulates the step of the fatty acyl reduction, the final step of the bombykol biosynthetic pathway to produce the terminal hydroxyl group. In order to probe the biochemical steps as well as underlying mechanisms regulated by PBAN, we have tested the effects of pharmacological agents on bombykol production by using an in vitro assay with pheromone glands. In addition, we have detected acyl CoA reductase activity in the pheromone gland of *B. mori* by using palmitoyl CoA as a substrate. The acyl CoA reductase requires NADPH, but not NADH, as a proton donor. Cell-free production of bombykol was attained by incubating the pheromone gland homogenate in the presence of NADPH, ATP and CoA. Removal of either NADPH, ATP or CoA from the incubation medium resulted in no stimulation of bombykol production, suggesting that the final two steps of the bombykol biosynthetic pathway are conducted by acyl CoA synthetase and acyl CoA reductase, sequentially. Based on these results, we discuss the biochemical mechanisms of sex pheromone production regulated by PBAN in *B. mori*.

05-093

TERMINATION OF SEX PHEROMONE PRODUCTION IN MATED FEMALES OF THE SILKWORM MOTH, *BOMBYX MORI* L.

Tetsu ANDO, Kie KASUGA, Hiroshi KATAOKA¹ and Akinori SUZUKI¹ Graduate School of Bio-Applications and Systems Engineering, Tokyo University of Agriculture and Technology, Fuchu, Tokyo 183, Japan. ¹Department of Applied Biological Chemistry, The University of Tokyo, Bunkyo-ku, Tokyo 113, Japan

A mating duration of more than 6 h was necessary to permanently terminate the production of the sex pheromone (bombykol) in the silkworm moth, *Bombyx mori* L. (Lepidoptera: Bombycidae), although the female formed a bursa copulatrix including a spermatophore and laid fertilized eggs even after mating for only 0.5 h. The 6-h mated female again produced bombykol if given an injection of synthetic pheromonotropic neuropeptide (PBAN), which is known to activate pheromone biosynthesis in a virgin female. Extracts of brain-suboesophageal ganglion (SG) complexes, which were removed from 6-h and 24-h mated females, showed strong pheromonotropic activities. These results indicated that the pheromone gland of the mated female maintained its ability to biosynthesize bombykol; however, it could not produce pheromone due to a suppression of PBAN secretion from the SG. Furthermore, bombykol titers did not decrease after mating in females with a transected ventral nerve cord, even after the injection of a spermatophore extract, suggesting that the suppression of PBAN secretion was mediated by a neural signal and not by a substance in the spermatophore. The mated females accumulated (10E,12Z)-10,12-hexadecadienoic acid, a precursor of bombykol biosynthesis, in their pheromone glands as did decapitated females.

05-094

PURIFICATION, CHARACTERIZATION AND PARTIAL AMINO ACID SEQUENCE OF INITIATORIN, A PROSTATIC ENDOPEPTIDASE OF THE SILKMOTH, *Bombyx mori* (L.) (Lepidoptera: Bombycidae)

M. Matsuyama, I. Tomita, M. Osanai

Department of Biology, Faculty of Science, Kanazawa University, Kanazawa, Japan

Initiatorin is a serine-endopeptidase secreted from the glandula prostatica gland of the silkworm, *Bombyx mori*. It acts as an initiator for sperm maturation in the spermatophore: (1) on inducing for motility of apyrene spermatozoa, (2) on dissociating eupyrene sperm bundles, (3) on initiating the arginine degradation cascade by degradation of arginine-rich proteins, and (4) on activating the zymogen of arginine carboxypeptidase which produces free arginine from peptide.

Purification of initiatorin was monitored by assay of hydrolyzing activity of BAEE (N α -benzoyl-L-arginine ethyl ester). Using affinity-chromatography with *p*-aminobenzamidine (ABA) as a ligand which is the strong inhibitor of initiatorin (82% inhibition by 0.1mM ABA), this enzyme was purified over 200-fold from the glandula prostatica of males.

Against BAEE as a substrate, Km-value of this enzyme is 2.43×10^{-4} M. Molecular weight of the purified initiatorin was determined as 30KDa by SDS-PAGE.

The determined N-terminal amino acid sequence of this initiatorin preparation is the same as that of another initiatorin preparation purified from the spermatophore of which molecular weight is 29KDa (Aigaki et al., 1994).

05-096

PROTEASES IN THE TESTIS OF THE SILKMOTH, *BOMBYX MORI* (L.) (LEPIDOPTERA: BOMBYCIDAE)

M. Uejima, H. Takahashi, M. Osanai

Department of Biology, Faculty of Science, Kanazawa University, Kanazawa, Japan

In the testis of the silkworm, *Bombyx mori* bundle of anucleate apyrene sperm dissociate and separate apyrene sperm move. On the other hand, it was found that initiatorin, a serine-endopeptidase localized in the glandula prostatica has capacities not only to dissociate bundles of eupyrene sperm but also to induce motility of apyrene sperm in the spermatophore. These findings suggest that also the dissociation of bundles of apyrene sperm and their motility acquisition in the testis may be caused by a protease(s).

Two proteases were detected in the testis during development of the silkworm. One shows L-alanine-*p*-nitroanilide (ANA)-hydrolyzing activity and the other N α -benzoyl-L-arginine ethyl ester (BAEE)-hydrolysing activity. These two enzymes were able to be extracted from the testis, only when the extracting solution contains a high concentration of cetyltrimethylammonium bromide (CTB). The enzyme activity of the former aminopeptidase (ANAAse) increases from day 3 of the 4th instar larva, reaches a maximum at day 2 of the 5th instar larva and then decreases. The enzyme activity of the latter endopeptidase (BAEEase) showed similar developmental changes to ANAAse. These activity maxima correspond to the time when a large number of spermatoocytes of apyrene sperm appear.

05-095

INITIATORIN INHIBITOR OF THE MALE GLANDULA PROSTATICA OF THE SILKMOTH, *BOMBYX MORI* (L.) (Lepidoptera : Bombycidae)

Y. Tanimura, I. Tomita, M. Osanai

Department of Biology, Faculty of Science, Kanazawa University, Kanazawa, Japan.

Initiatorin is a serine-endopeptidase secreted from the glandula (g.) prostatica of the male silkworm, *Bombyx mori*. Like trypsin, this enzyme has a capacity to hydrolyze N α -benzoyl-L-arginine ethyl ester (BAEE). Initiatorin was first precipitated ammonium sulfate 30-80% at saturation, then purified using FPLC on an affinity-chromatography fixed with *p*-aminobenzamidine as a ligand. At that time when the extract from the g. prostatica was treated with ammonium sulfate, BAEEase activity was highly increased, suggesting that the presence of an inhibitor in this gland. Thus, this initiatorin inhibitor (PII) was purified from the g. prostatica. Gel filtration FPLC was carried out on a Superdex™75. Prepared PII is a heat-stable peptide of which molecular weight is under 10kDa. This natural inhibitor inhibits BAEEase activity of bovine trypsin as well as that of initiatorin. The inhibition on trypsin is stoichiometric and considered to be noncompetitive. The dissociation constant was calculated as about 1.0mg per ml.

Its physiological functions may be not only to protect cells from harmful effect of initiatorin but also to control motility acquisition of apyrene sperm.

05-097

THE ANGIOTENSIN CONVERTING ENZYME RELATED CARBOXYDIPEPTIDASE OF THE BUFFALO FLY EXPRESSED IN MATURING TESTES.

G. Wijffels, C. Fitzgerald, J. Gough, G. Riding, C. Elvin, D. Kemp, P. Willadsen.

CSIRO Division of Tropical Animal Production, Indooroopilly, Queensland, Australia.

The angiotensin converting enzymes (ACEs) are membrane bound carboxydiptidases ubiquitous in mammalian systems. They are involved in the regulation of the activities of several bioactive peptides. An enzyme similar to the ACEs has been purified and cloned from the adult stage of the buffalo fly (*Haematobia irritans exigua*) - a close relative of the horn fly. The buffalo fly enzyme, HieACE, is not membrane bound and behaves as a 70kD doublet in reducing SDS-PAGE.

HieACE was purified from whole fly preparations by lectin and ion exchange chromatographies. The purified HieACE has similar enzymatic activity to the mammalian ACEs and displays similar specificity to ACE peptide substrates such as angiotensin I, bradykinin, substance P and cholecystokinin. Sequences of peptides resulting from an endo-Lys-C digest of purified HieACE were used to design PCR primers and a DNA fragment amplified from adult buffalo fly cDNA was used to screen a cDNA library. The coding region of a full length cDNA clone predicted an ACE-like carboxydiptidase with 42% amino acid identity to mammalian testicular ACEs.

An antiserum raised to the purified HieACE has shown that in the unfed adult fly, HieACE expression was restricted to the compound ganglion and posterior midgut. However, in a curious parallel to the mammalian system, expression of the enzyme is induced in the maturing male reproductive system after the first blood meal.

05-098

EXPRESSION OF ANGIOTENSIN CONVERTING ENZYME HOMOLOGUES IN THE LARVAE OF HIGHER DIPTERA.

G. Wijffels, J. Gough, A. Don, D. Kemp.
CSIRO Division of Tropical Animal Production, Indooroopilly, Queensland, Australia.
The characterisation and cloning of the adult buffalo fly homologue of the mammalian angiotensin converting enzyme (ACE) has been recently described (Wijffels *et al.* 1996). The fly homologue, HieACE, has enzymatic similarities to the ACEs and exhibits 42% sequence identity with testicular ACE. HieACE expression in the unfed adult fly is restricted to the compound ganglion and posterior midgut, although expression is induced in the male reproductive tissues after the first blood meal.

However, expression of HieACE and its homologues in other diptera is not restricted to the adult stage. The ACE-like enzymes were detected by Western blot analyses in the third instar stages of the buffalo fly, sheep blowfly (*Lucilia cuprina*) and *Drosophila*, and fourth instar larvae of the mosquito, *Aedes vigilax*. In fact, all larval stages of the sheep blowfly expressed the *Lucilia* ACE homologue. In these species, HieACE and its counterparts were approximately 70kD in size and not membrane bound. The ACE-like enzymes have a broad tissue distribution in the third instar larvae of the buffalo fly and sheep blowfly. HieACE and its *Lucila* homologue were detected throughout the gut, the salivary glands and the compound ganglion. This contrasts with the restricted tissue distribution of the adult flies of these species and suggests a different role for the dipteran ACE-like enzymes in the larval stages.

Wijffels, G., Fitzgerald, C., Gough, J., Riding, G., Elvin, C., Kemp, D., and Willadsen, P. (1996) "Angiotensin Converting Enzyme" of the Dipteran Species, *Haematobia irritans exigua*, and its Expression in Maturing Male Reproductive System. *European J. Biochem.* (in press)

05-100

PURIFICATION AND CHARACTERIZATION OF THREE ISOFORMS OF VITELLIN IN *Rhodnius prolixus*

A.P. Salerno, M.D.A. Petretski and H. Masuda
Departamento de Bioquímica Médica, ICB, CCS, Universidade Federal do Rio de Janeiro, Brazil.

Vitellogenins (VTG) are high molecular weight phospholipoglycoproteins. They are taken up from hemolymph by the oocytes by receptor-mediated endocytosis. After incorporation by the ovaries, they are called vitellins (VT). Vitellin, the main protein of *Rhodnius prolixus* oocytes was purified by means of ion exchange chromatography DEAE TOYO-PEARL. Three VT isoforms were identified and they were called VT₁, VT₂, VT₃.

All VT isoforms have the same neutral lipids, but were heterogenous with respect to phospholipids composition. VT₁ have only phosphatidylcholine, whereas VT₂ showed phosphatidylcholine, cardiolipin, and a non-identified lipid and VT₃ had phosphatidylcholine, phosphatidic acid, sphingomyelin, cardiolipin, and the same non-identified lipid. The phosphate content of each isoform were analyzed after lipid extraction and it was also heterogenous, VT₁ being the less phosphorylated and VT₃ the most heavily phosphorylated isoform. Sugar composition was analyzed by means of paper chromatography. VT₁ have mostly glycose than mannose and in contrast VT₃ have mostly mannose than glycose.

When metabolic labelled ³²Pi-VT isoforms were injected into the hemocel of vitellogenic females, VT₃ was taken up with a rate about three times higher than that observed for VT₁ and VT₂.

Supported by CNPq, FINEP, and FAPERJ.

05-099

DISTRIBUTION AND ACCUMULATION OF STORAGE PROTEIN IN OVARY OF *HYPHANTRIA CUNEA* DRURY

Young-Jin Kang, Ja-Hyang Cho, Soon-Kum Hwang, Hyang-Mi Cheon, Sook-Jae Seo
Department of Biology, College of Natural Science, Gyeongsang National University - 1 Department of Pathology, Hospital of Gyeongsang National University, Chinju 660-701, Korea

The accumulation and uptake of storage protein in ovary of fall webworm, *Hyphantria cunea* Drury, were investigated using autoradiograph, Western blot, and immunocytochemistry. Storage protein is found at high level in hemolymph as well as fat body during pupal stage, while in ovary storage protein begin to appear at trace level in 6 day-old pupae and accumulate until adult stage.

During pupal stage storage protein in hemolymph penetrates through the layer of tunica propria and gains access to oocyte. Storage protein uptake occurs across the brush border from the follicular epithelial cells to the oocyte, producing rapid accumulation of storage protein in yolk spheres.

In the oocyte, storage protein is incorporated to in the small protein granules, which are fused together to form large yolk sphere. This transportation of storage protein seems to continue until the formation of vitelline membrane.

05-101

A Highly Phosphorylated Low Molecular Weight Protein from the Oocytes and Hemolymph of *Rhodnius prolixus* : Isolation and Partial Characterization.

M.A.C. Silva-Neto¹, E. Fialho¹, G.C. Atella¹, M.C. Paes¹, R. Zingali¹, J.H. Petretski², E.W. Alves² and H. Masuda¹. ¹Departamento de Bioquímica Médica - ICB - CCS - UFRJ - Rio de Janeiro - RJ - Brazil. ²Laboratório de Química e Função de Proteínas e Peptídios-CBB-UENF - Campos - RJ - Brazil.

Vitellin is a phospholipoglycoprotein which composes the yolk of oviparous organisms. When *Rhodnius* females are fed with blood enriched with ³²Pi it is possible to label its phosphoproteins metabolically. This approach showed that besides Vitellin a second phosphoprotein is also present in these oocytes. We have isolated this protein through gel filtration on Sephadex G-75, anion exchange on DEAE Toyo Pearl and Mono Q 5/5 HR. The purified molecule is a single band on Tricine gels with 8 kDa of molecular weight but it shows a native weight of 17 kDa. Aminoacid composition shows a high content of Serines (25 %) and these residues are the only targets for phosphorylation. NH₂- terminal sequencing shows no significant homology with available sequences. Another phosphoprotein was also isolated from hemolymph. Its identity with the oocyte phosphoprotein was confirmed by NH₂- terminal sequencing. Both radiolabelled molecules are ready taken up by growing ovaries following injection into hemocel of adult females. The phosphoprotein present inside the oocyte is a substrate for purified Casein Kinase II, which indicates the possibility of post-endocytotic processing. During embryogenesis, a decrease in this phosphoprotein is detected on day 5. Although, the function of this molecule is not clear we were able to determine some calcium binding capacity using ⁴⁵Ca in blotted material. These preliminary data suggest a possible role at the initial phase of development.

Supported by CNPq, FINEP, FAPERJ, and CAPES(UFRJ).

05-102

A COLD-INDUCIBLE GENE ISOLATED FROM DIAPAUSE EGGS OF *BOMBYX MORI* USING RNA DIFFERENTIAL DISPLAY: SEQUENCING OF THE CDNA AND ITS GENE EXPRESSION

T. Niimi¹, O. Yamashita, T. Yaginuma

Laboratory of Sericulture and Entomoresources, School of Agricultural Sciences, Nagoya University, Chikusa, Nagoya (464-01), Japan - 1 Present address: Department of Cell Biology, Biozentrum, University of Basel, CH-4056, Basel, Switzerland

As an initial step to isolate functional molecules involved in maintenance and/or termination of embryonic diapause of *Bombyx mori*, we have performed RNA differential display using cDNAs prepared from diapause eggs, and then obtained a PCR product expressed much more in eggs exposed to 5°C than in eggs incubated at 25°C continuously. Using this PCR product (Dif-L2), a cDNA was cloned from a cDNA library made with eggs. The cDNA for Dif-L2 contained 2400 nucleotides and an ORF consisting of 678 amino acids, with both start and stop codons. Northern hybridization and RT-PCR experiments showed that an RNA with about 2.5 kb increased in diapause eggs exposed to 5°C for 10-20 days while it was at very lower levels in eggs incubated at 25°C, with the same ages. Although protein(s) similar to Dif-L2 were not yet found using data bank, Dif-L2 protein had a domain specific to proteins which were translocated into nucleus. These results suggest that the gene expression for Dif-L2 is induced by cold-treatment and that Dif-L2 functions within nuclei in *Bombyx* eggs.

05-104

QUINONE-TANNING IN THE EGG-SHELL OF THE FALSE MELON BEETLE, *ATRACHYA MENETRIESI* FALDERMANN (COLEOPTERA: CHRYSOMELIDAE)

M. Yago* and H. Sato**

*Department of Biochemistry, School of Dentistry, **Department of Cell Biology and Neuroanatomy, School of Medicine, Iwate Medical University, Morioka, 020, Japan

A newly laid insect egg is surrounded by two envelopes. The inner envelope is the vitelline membrane and the outer is the chorion or eggshell. In some species, the envelopes sclerotize after oviposition. Such a case was previously reported in dragonfly eggs (Kawasaki *et al.*, 1974). The dragonfly vitelline membrane, which is stabilized by intermolecular crosslinks in the form of di- and trityrosyl residues, sclerotizes further probably by the action of phenoloxidase, accompanied by a change in color from yellow to dark brown. In this paper, we report another example of the sclerotization of egg envelopes of the false melon beetle, *Atrachya menetriesi* Faldermann. The newly laid eggs of the chrysomelid beetles are yellow, and the color changes to dark brown after several h. We collected the eggs, and prepared their scleroprotein fractions. Then, the fractions were subjected to column chromatography with BioGel P-2 after being hydrolysed. Several phenolic compounds were found in the hydrolysates, and some of them were identified as the conjugates of 3,4-dihydroxyphenylacetic acid and L-cysteine, which were 5-S-cysteinyl-, 2-S-cysteinyl-, and 2,5-S,S-dicysteinyl-3,4-dihydroxyphenylacetic acids. The content of 5-S-cysteinyl-3,4-dihydroxyphenylacetic acid, the major compound, in the brown eggs was substantially lower than that in the yellow eggs. 3,4-Dihydroxyphenylacetic acid was detected as a female-specific compound in the whole bodies of the insects. These results suggested that quinone tanning took place in the eggs of the beetles, using 3,4-dihydroxyphenylacetic acid as the precursor of the tanning or sclerotizing agent. The egg envelopes are stabilized probably by the crosslinks formed from the quinone of 3,4-dihydroxyphenylacetic acid and cysteinyl residues in the proteins.

05-103

TIME INTERVAL MEASURING ENZYME FOR RESUMPTION OF EMBRYONIC DEVELOPMENT AND FUNCTION OF EGG-SPECIFIC PROTEIN IN THE SILKWORM, *BOMBYX MORI* H.Kai, N.Katagiri, M.Isobe¹ and S.Suwan¹
Dep of Biochem and Biotech, Fac of Agriculture, Tottori Univ, Koyama, Tottori Japan - 1 Lab of Org Chem, School of Agricultural Sciences, Nagoya Univ, Chikusa, Nagoya Japan

EA4 is a DNA-dependent ATPase which has the capability of measuring a time-interval for resumption of embryonic development in diapause eggs of the *Bombyx* silkworm. PIN peptide regulates the EA4. We asked what is the mechanism by which EA4 measures time and PIN regulates the timer.

At 5 °C, EA4 activity was very low initially, but in 2 weeks the activity increased sharply and then rapidly fell. The period required to activate the enzyme was equivalent to that observed *in vivo* and was coincident with the chilling period indispensable for diapause termination. In mixing of PIN with EA4, the clock-run of EA4 was delayed to the period equivalent of PIN inclusion. PIN may hold the timer probably by forming a PIN-EA4 substructure. PIN was identified. The full sequence of PIN was 100% identical to a portion of amino acid sequence of Egg-Specific Protein (ESP); the 19th-56th amino acid residues of the ESP, in which the 1st-18th residues are likely to be a signal peptide and the 57th-58th residues (K-R) are possibly a cleavage site.

EA4 may originally be complexed with PIN, which resulted after processing from ESP. In winter cold, PIN and EA4 may dissociate from each other. The dissociation may cause EA4 to undergo conformational changes, resulting in a time-interval activation of the enzyme which is crucial for diapause termination.

05-105

RHYTHM OF PERIOD PROTEIN EXPRESSION IN MALPIGIAN TUBULES OF *DROSOPHILA MELANOGASTER*: EVIDENCE FOR HEAD-INDEPENDENT CIRCADIAN CLOCK

D. M. Hege, J. Giebultowicz,

Dept. of Entomology, Oregon State University, Corvallis, OR USA

Period (per) gene is part of the molecular feedback loop involved in circadian clock of *Drosophila*. *Per* is expressed rhythmically in the brain and appear to control the rhythms of locomotor activity and eclosion. We have found that *Drosophila* excretory epithelium (Malpighian tubules) express *per* protein (PER) rhythmically, even in brainless flies. Our initial studies of *per* expression in *Drosophila* were carried out on transgenic flies (XLG) (gift from Dr. J. Hall) which contain 99% of the *per* coding region fused to all of *E.coli lacZ* gene. XLG flies were shown to express the PER-reporter fusion protein rhythmically in relevant cells in the brain (R. Stanewsky and J. Hall, pers. comm.). The following observations will be reported: (i) Expression of PER in Malpighian tubules (MTs) is rhythmic, PER is first detected in the cytoplasm and then, at the end of dark phase, in the nucleus. (ii) MTs of *per⁰* flies do not express PER. (iii) Rhythm of PER in MTs continues in constant darkness. (iv) Rhythm of PER in MTs continues and phase shifts in response to shifted photoperiod in brainless flies. (v) PER expression in MTs is "turned on" at eclosion. MTs of insects in the pupal stage are largely inactive; interestingly, PER was not detected in MTs at any time during the day preceding eclosion. Thus, PER in MTs seem to be developmentally regulated, and its appearance may coincide with the onset of adult secretory functions.

In summary, our results suggest that PER in Malpighian tubules behaves very similarly to PER in lateral neurons of the brain: it cycles and translocates into the nucleus in the wild flies in LD and DD and is absent in *per⁰* flies. Moreover, the PER rhythm continues and phase shifts in brainless flies. These findings suggest that MTs may be the site of a self-contained circadian clock.

05-106

GROWTH AND DEVELOPMENT IN *TENEbrio MOLITOR* LARVAE CHRONICALLY EXPOSED TO GAS MIXTURES: VARYING O₂ PRESSURES IN N₂ AND He.

S. Greenberg and A. Ar., Department of Zoology, Tel Aviv University, Ramat Aviv, Tel Aviv 69978, Israel.

This study was designed to examine the response of *Tenebrio molitor* larvae to different O₂ pressures during development, including two different hypoxic environments: 10% O₂ in N₂ and in He. Oxygen diffusion in He is about four times faster than in N₂. Larvae reared from eggs at 25°C and 70% RH, in four O₂ environments: hypoxia (10% O₂ in N₂ and in He; PO₂=74 Torr), hyperoxia (40% O₂ in N₂; PO₂=297 Torr) and normoxia (air; PO₂=155 Torr). Pupation of first larvae exposed to normoxia and hyperoxia started after day 125 post hatching, while in hypoxic atmospheres it began after day 160. 48% of the larvae survived the N₂ hypoxia; 76% survived in normoxia; 96% in hyperoxia; and 80% in 10% O₂ in He hypoxia. Survival differences were significant ($X^2=69.7$, $p<0.01$; initial $n = 128, 118, 93$ and 111 , respectively). Average body masses on day 180 after hatching differed and were $64.5 \text{ mg} \pm 11.6\text{SE}$, $143.6 \text{ mg} \pm 10.6\text{SE}$, $133 \text{ mg} \pm 9.7\text{SE}$ and $79.3 \text{ mg} \pm 4.3\text{SE}$ in N₂ hypoxia, normoxia, hyperoxia and He hypoxia ($n=25$ in each group, $p<0.01$). Growth curves fitted to larval body mass were similar between normoxic and hyperoxic treatments but had a 4-fold significantly higher developmental rate than in hypoxic groups.

Oxygen growth response to hypoxia may exist and be sensitive to oxygen pressures. Increased oxygen flux in He hypoxia was shown to increase survival.

05-108

THE SERINE PROTEINASE INHIBITORS IN COCKROACH INTESTINES

D.P. Zhuzhikov

Department of Entomology, Moscow State University, Moscow, Russia

There are only few insect species, which have proteinase inhibitors in intestine. The highest level of trypsin-like serine proteinases activity are determined in posterior midgut. There is not occurs digestion of proteins in the crop and anterior midgut. The thermostable serine proteinase inhibitors were discovered in crop and anterior midgut of the 6 cockroach species: *Blatta orientalis*, *Blattella germanica*, *Periplaneta americana*, *Nauphoeta cinerea*, *Blaberus craniifer*, *Gromphadorina* sp. Their activity was assessed by gelatin lysis of film for aerophoto after exposure to heat-treated extract (10 min in boiling water). The inhibitors suppress the activity of the bovine trypsin and enzymes in different levels as of the same species of cockroach as of some others. Therefore, the cockroaches of various species have the different composition of proteolytic enzymes and different structure of inhibitors. It is supposed, that inhibitors in the gut of irregularly feeding cockroaches promote food conservation in crop and anterior midgut and protect midgut epithelium from protease impact, particularly in starvation periods.

05-107

CHARACTERISTICS OF DIGESTIVE PROTEASES IN VARIOUS INSECT GUTS

A. Mochizuki

Laboratory of Entomology, Tohoku National Agricultural Experiment Station, Yotsuya, Omagari, Akita, Japan

The nature of proteases in gut digestive fluid are different between insect order. It has been reported that some lepidopterous species mainly have trypsin like serine-proteases, orthopterous and hymenopterous species have chymotrypsin, and coleopterous species have cysteine-proteases. However only a few data have been useful. I presents here the differences of the nature of digestive proteases between some insect orders by using polyacrylamide gel analysis. Gut was dissected from insect abdomen in a pre-chilled saline on ice and centrifuged to take digestive fluid. The fluid was electrophoresed on 4% gelatin-10% SDS-PAGE gel. The gel was incubated with or without some kinds of protease inhibitors and stained with CBB dye. Subunits of protease can be seen as transparent bands in a blue background. When the gel is incubated with a protease inhibitor, inhibited bands are stained and fade into the background. For example, the main gut protease of *Chilo suppressalis* (Lepidoptera: Pyralidae) is serine-protease, so that it was inhibited by PMSF and corresponding bands on a gel were stained with CBB. On the other hand, that of *Lissorhoptrus orzohilus* (Coleoptera: Curculionidae) was not inhibited by serine-protease inhibitor, but inhibited by cysteine-protease inhibitor, iodine acetate, NEM, pHMB and leupeptin, therefore the main protease of this species is cysteine protease. I will show the results on the other species including Orthoptera, Diptera, Odonota.

05-109

NEW MIDGUT PROTEASE ACTIVITIES IN COLORADO POTATO BEETLE LARVAE

C. Novillo-Almendros, F. Ortego, P. Castañera

Centro de Investigaciones Biológicas, CSIC, Madrid, Spain

The midgut of the Colorado potato beetle larvae, *Leptinotarsa decemlineata* Say (Coleoptera: Chrysomelidae) has mildly acidic pH, and cathepsin B, D, H and L have been reported to provide the major midgut proteolytic activities.

We have characterized a new endoprotease activity using the chymotrypsin-like specific substrate N-succinyl-L-alanyl-L-alanyl-L-prolyl-L-phenylalanine-p-nitroanilide. This novel proteinase, with a pH optimum of 6.5-7.0, was not activated or inhibited by thiol compounds and cysteine specific proteinase inhibitors. Among several serine proteinase inhibitors tested, chymostatin resulted the most effective. Elastase-like activity, using the specific substrate N-succinyl-alanine-alanine-alanine-p-nitroanilide, was not detected.

The major exopeptidase found in the larval midgut was a leucine aminopeptidase activity with a pH optimum of 7.5. Carboxypeptidase A and B activities were not detectable by using hippuryl-L-phenylalanine and hippuryl-L-arginine as substrates, respectively.

05-110

PROTEINASES OF COLORADO POTATO BEETLE AND THEIR PLANT PROTEIN INHIBITORS

Al.V. Konarev Al.V. and S.R.Fasulati
All-Russian Institute for Plant Protection,
St Petersburg, Russia

Colorado potato beetle (CPB) larvae and adults digestive proteinases were separated by isoelectric focusing (IEF) in PAG and some bands with pI value of 4 to 10 were detected with use of gelatine layer of photofilm. The majority of bands were found to be inhibited by p-CMB. The cross-methods were used for the search of plant protein inhibitors active to CPB proteinases. The water-soluble proteins from bread wheat endosperm and potato tubers and leaves were applied on gels by wide strips and separated by IEF. The gelatine replicas (on photofilms) were obtained. The narrow pieces of replicas were developed by trypsin, chymotrypsin, subtilisin, ficin and wheat germinated grain cysteine proteinases for detection of inhibitors. The CPB proteinase samples were applied on IEF gels by wide strips and separated as well. The gelatine replicas were superimposed on IEF gels with CPB proteinases so that plant protein bands were perpendicular to proteinase bands. The proteinases digested gelatin of replicas as transparent bands narrowed or interrupted in points of intersection with bands of their inhibitors. The comparison of results of cross analysis with patterns of standard proteinase inhibitors have shown that some CPB proteinase bands are inhibited by wheat cysteine proteinase inhibitors and some others are inhibited by trypsin and chymotrypsin inhibitors from potato tubers and damaged leaves. It was found that potato varieties vary in capability to accumulate inhibitors of trypsin, chymotrypsin, subtilisin and elastase in damaged leaves. The resistant to CPB varieties Zarevo, Zov and Liza accumulated inhibitors in contrast to susceptible varieties.

05-111

INVESTIGATION OF PROTEIN INHIBITORS OF TRYPsin-LIKE PROTEINASES AND CALPAIN I AND CALPAIN II ACTIVITIES IN TISSUES AND ORGANS OF SILKWORM, BOMBYX MORI L.

S.M.Klunova, N.V.Tarassenko, E.Yu.Kolobova,
Yu.B.Philippovitch.

Laboratory of insect biochemistry, chair of organic and biological chemistry of Moscow State Pedagogical University, Moscow, Russia. The dynamics of protein inhibitor activity of trypsin-like proteinases was studied in haemolymph, carcass, fat body, fibroin and sericine divisions of silk glands in silkworm at the final stage of its larval development. Little changes of protein inhibitor activity were shown in haemolymph, whereas it markedly increased in the other tissues by the end of the 5th age and decreased practically to the initial level by the third day of the cocoon spinning. Five peaks of inhibitor activity differed for pI values was found by isoelectrofocusing both in fibroin and sericine parts of silk glands. We have found the high level of Calpain I and Calpain II activity both in fat body and in fibroin division of the silk glands. In this connection protein inhibitors of Ca^{++} -dependent neutral proteinases activity in the silkworm will be studied.

The role of the protein inhibitors of peptidohydrolases and the complex of proteolytic enzymes in nitrogen metabolism in tissues and organs of silkworm is discussed.

05-112

IN VIVO MANIPULATION OF AMINOPEPTIDASE AND CARBOXYPEPTIDASE ACTIVITIES IN THE MOSQUITO, ANOPHELES STEPHENSI LISTON (DIPTERA: CULICIDAE).

P.T.Docherty and P.F.Billingsley

Department of Zoology, University of Aberdeen, Aberdeen, AB9 2TN, Scotland, U.K.

Enzymes are considered targets for anti-parasites vaccines because of their functional importance. A carboxypeptidase-type enzyme in the tick (1) is the proposed Bm91 vaccine antigen and aminopeptidase is currently under trial as a vaccine against *Haemonchus contortus* (2). Aminopeptidase has also been implicated in mosquito refractoriness to *Plasmodium* parasites (3).

We have characterised two midgut enzymes of *Anopheles stephensi* which display characteristics typical of aminopeptidase M and carboxypeptidase A. Aminopeptidase appears to be synthesised in a form bound to the midgut membrane by a glycosyl phosphoinositol anchor, then cleaved into a soluble form, active in the lumen and associated with the peritrophic matrix. Carboxypeptidase also appears to have both membrane-bound and soluble forms.

Mosquitoes fed aminopeptidase inhibitor revealed that a possible "cascade" mechanism of synthesis exists. In addition, mosquitoes fed aminopeptidase or carboxypeptidase inhibitors seem able to compensate for inhibition of either peptidase, with increased synthesis of the other. When fed both inhibitors, aminopeptidase and carboxypeptidase activities were only partially reduced. This manipulation of activities has adverse effects on mosquito fecundity.

AEROBIC METABOLISM IN THE PAUNCH OF THE HIGHER TERMITE NASUTITERMES WALKERI

M. Slaytor, P. C. Veivers and N. Lo

Department of Biochemistry, The University of Sydney, Sydney, N. S. W. 2006, Australia

The recent demonstration by Breznak and co-workers that the hindgut of both higher and lower termites, previously thought of as an anaerobic environment, contains a substantial amount of O_2 suggests that a significant amount of aerobic metabolism is taking place. We have been measuring in the hindgut the activities of the major enzymes of aerobic metabolism as well as the enzyme activities involved in the activation of potential substrates for energy such as glucose, xylose, pyruvate and acetate. The pyruvate dehydrogenase (PDH) complex and the tricarboxylic acid cycle are active in the hindgut. The activity of the PDH complex is of particular interest as it is inactive in the aerobic termite body tissues. This suggests that pyruvate produced in termite tissues by glycolysis is a major substrate for bacterial growth and energy. Pyruvate cannot be detected in the hindgut suggesting that pyruvate is metabolised as soon as it enters the hindgut. O_2 utilisation by the bacteria is extremely sensitive to variations in pyruvate concentration, much more so than other substrates such as glucose, xylose, acetate or alanine. In contrast, the enzymes of glucose activation in the hindgut are either absent (glucose phosphotransferase) or have low activity consistent with the absence of cellulase activity in the hindgut and suggesting that glucose is not a normal bacterial substrate in the hindgut. There is evidence that xylan, one of the components of hemicellulose, is metabolised both by the termite and its symbiotic bacteria as the enzymes of xylan metabolism are evenly distributed throughout the gut and that xylulokinase, a key enzyme in the activation of xylose, is active (30 nmol/termite/h) in the bacteria. The role of acetate in the hindgut is equivocal. Its high concentration (27 mM) suggests that it is not metabolised to any great extent, consistent with the traditional view of short chain fatty acids being the end products of anaerobic metabolism. However, the activity of acetyl CoA synthetase, the enzyme responsible for the activation of acetate, is 18 fold higher in the hindgut (213 nmol/termite/h) than in the body (12 nmol/termite/h), the expected site of acetate metabolism.

05-114

CROP EMPTYING IN RELATION TO FOOD TYPE IN THE CRICKET, *TELEOGRYLLUS COMMODUS* WALKER, AND THE COCKROACH, *PERIPLANETA AMERICANA* L.

P. Cooper
Division of Botany and Zoology, Australian National University, Canberra, ACT, Australia

Crop emptying in herbivorous insects may determine the rate of digestion and absorption, as the emptying determines the rate of movement of food into the midgut and hindgut and may influence the interval between meals. Studies on acridids have indicated that crop emptying is under neural and/or endocrine control, but these studies have ignored the role that the morphology of the gut may play in crop emptying as well. The cricket has an unusual gut structure, in that the proventriculus is a muscular, cuticular-toothed lined organ and then connects into a very short midgut. The proventriculus acts as a second compartment for mixing of food, in addition to the crop, and is separated from the crop by a muscular sphincter. Rather than a single continuous flow-stir tank reactor (CSTR) (as defined by chemical reactor theory), the cricket has two CSTRs, followed by a short plug-flow reactor (PFR), the midgut. In contrast the cockroach, similar to acridids, has the single CSTR (the crop), followed by a relatively long PFR. Chemical reactor theory would suggest that the passage time of food would increase as more CSTR systems are present. Our work indicated that passage time of food depended upon the type of food ingested in both the crickets and cockroaches, with fresh lucerne passed from crop to midgut at nearly the same rate in the two insects, while rye grass passed more slowly through the cricket. This indicates that food type plays an important role in determining rate of crop emptying as previously shown for acridids. In addition, the presence of the CSTR (proventriculus) in the cricket does not necessarily lengthen passage time, implying that changes in gut peristalsis can influence the food movement such that the CSTR mimics a PFR.

05-116

EFFECTS OF SOYBEAN TRYPSIN INHIBITOR, GOSSYPOL AND TANNIC ACID ON THE DIGESTIVE PHYSIOLOGY AND GROWTH OF THE LARVAL *HELICOVERPA ARMIGERA* (HÜBNER)

C. Z. Wang, J.D. Qin

Institute of Zoology, Chinese Academy of Sciences, Beijing 100080, China

The effects of soybean trypsin inhibitor (STI), gossypol and tannic acid on the digestive physiology and growth of cotton bollworm *Helicoverpa armigera* (Hübner) were studied. Each of these three agents inhibited larval midgut proteolytic activity *in vitro*; STI was the most effective. When incorporated into an artificial diet, 0.84% (dry weight) STI significantly reduced the high alkaline trypsin-like enzyme activity by 18%; 0.3% tannic acid significantly decreased the low alkaline trypsin-like enzyme activity and total proteolytic activity by 22% and 18% respectively, and 0.3% gossypol had no significant effect on proteolysis. All these three agents markedly suppressed the growth of the larvae when incorporated into the diet in these ratios. The coexistence of STI and gossypol or tannic acid respectively declined the low alkaline trypsin-like enzyme activity by 34% and 66%, the high alkaline trypsin-like enzyme activity by 30% and 55%, and the total proteolytic activity by 30% and 66%. The coexistence of STI and tannic acid also reduced chymotrypsin-like enzyme activity by 53%. Both gossypol and tannic acid potentiated the larval growth inhibitory activity of STI, and this fact implicates the protease inhibitor gene engineered into the cotton plant with high gossypol and/or tannic acid content may achieve greater protection against the cotton bollworm.

05-115

EFFECT OF *Annona muricata* SEED EXTRACTS ON THE NUTRITION INDICES OF *Heliothis armigera* LARVAE

A. D. Permana, Y. Yus, S. Soelaksono

Department of Biology FMIPA - ITB and IUC Life Sciences - ITB, Bandung, Indonesia.

Effect of *Annona muricata* seed extracts on the nutrition indices of the fifth-instar of *Heliothis armigera* larvae was carried out using artificial diet. The result indicated that the relative consumption rate was decreased, and consequently, the growth was inhibited. Interestingly it seems that in response to the toxic materials from the extracts, the larvae compensated by increasing the food assimilation, however this compensation was not enough to support the normal growth.

05-117

THE EFFECTS OF *DERRIS ELLIPTICA* ROOT EXTRACTS ON THE FOOD INTAKE, FOOD UTILIZATION, GROWTH AND OXYGEN CONSUMPTION IN THE FIFTH-INSTAR LARVAE *HELIOTHIS ARMIGERA* (LEPIDOPTERA: NOCTUIDAE)

I. Ahmad, Nursal & S. Sastrodihardjo

Inter University Center for Life Sciences, and Dept. of Biology, Institut Teknologi Bandung, Bandung, Indonesia

The effects of feeding artificial diets treated with various concentrations of *Derris elliptica* root ethanol extract or ether fraction extracts to the fifth-instar *Heliothis armigera* larvae are presented. The results showed that, in general, the growth and efficiencies of food use were significantly lower in the case of derris treated larvae than that of the controls, with the exception that the larvae treated with derris root ethanol extracts had significantly higher Approximate Digestibility (AD) values as compared to that of the controls. As expected, oxygen consumption rate was significantly lower on larvae treated with derris root extracts.

05-118

GLYCINE SECRETION AS A NOVEL STRATEGY OF INSECTS AGAINST CHEMICAL DEFENSE OF HOST PLANTS

K. Konno, C. Hirayama, H. Shinbo

National Institute of Sericultural and Entomological Science

1-2 Ohwashi, Tsukuba, Ibaraki 305, Japan

We found that a considerable amount of free glycine exists in the digestive juices of several leaf-feeding Lepidopteran larvae. The concentration of glycine has very clear correlation with the protein denaturing activity of the host plant. We found that the leaves of the privet tree, *Ligustrum obtusifolium*, have extremely strong protein denaturing activity enough to make a protein innutritive. The denaturing activity closely resembles those of polyphenolics, general defense agents widespread throughout plants. The species which feed on this host plant have an extremely large amount of glycine in their digestive juice. The concentration reaches 50-60 $\mu\text{moles/ml}$ (0.4%) in *Dolbina tancrei* (Sphingidae) and *Brahmaea wallichii* (Brahmaeidae), both of which are specialists to the privet tree. We demonstrate that free glycine can completely inhibit the denaturing activity of the privet leaf in vitro, and that free glycine can prevent the protein from becoming innutritive using bioassay.

This is the first demonstration of the fact that such a simple molecule as a glycine can work as, and is actually used by herbivores as a counteracting agent against denaturing activity of plants. We believe that this is a good example of chemical adaptation and coevolution between plants and herbivores.

05-120

THE EFFECT OF AMINO ACIDS ON SODIUM UPTAKE BY THE MIDGUT OF THE CECROPIA LARVA.

S. Nedergaard, Biochemical Department, August Krogh Institute, University of Copenhagen, Denmark.

It has for some time been assumed that sodium uptake by the larval midgut of some herbivorous insects takes place via the potassium/amino acid co-transporter, which has a higher affinity for sodium than for potassium at low concentrations of the ions (Hanozet et al., 1992). Chamberlin, (1990), measured sodium uptake in the midgut of *Manduca sexta* larvae in the presence of all the naturally occurring amino acids. Recently, it has been shown that sodium can be taken up by the Cecropia larval midgut without any amino acids present in the bathing solutions (Nedergaard and Wolters, in press). The potential difference across the midgut, normally 100 - 160 mV, is favorable for sodium uptake, but can account for only about half of the uptake. The presented results show the effects of an amino acid, leucine, on the sodium uptake by the larval midgut. The presence of leucine increases the sodium flux to nearly the double of the flux in the absence of amino acids measured across isolated tissue. A similar effect is also observed using brush border membrane vesicles prepared from the Cecropia midgut tissue.

INDUCTION OF A K^+ -DEPENDENT LEUCINE TRANSPORT IN *XENOPUS LAEVIS* OOCYTES BY INJECTION OF mRNA ISOLATED FROM THE MIDGUT OF THE SILKWORM *BOMBYX MORI*.M. Casartelli MG Leonardi, P Parenti¹, B Giordana

Dipartimento di Biologia - 1 Dipartimento di Fisiologia e Biochimica Generali, Università di Milano, Milano Italia

Lepidopteran larval midgut presents two different cell types: the goblet cells, responsible for ion regulation, and the absorptive columnar cells.

The proton pump on the luminal membrane of the goblet cells, associated to a $\text{K}^+/\text{2H}^+$ antiporter, generates the high lumen-positive electrical potential difference (100-150 mV) and the steep luminal K^+ concentration (150mM) which drive the absorption of amino acids by the K^+ /amino acid symporters localized on columnar cell microvilli.

The injection of poly(A)⁺ mRNA isolated from *Bombyx mori* midgut into *Xenopus laevis* oocytes determined the appearance, 3-5 days after injection, of a K^+ -dependent uptake of radiolabelled L-leucine. The K^+ -dependent leucine transport was detectable with an external cation concentration of 20 mM and represented a 50% increase of basal leucine uptake, which in non-injected and water-injected oocytes was Na^+ -independent.

Since the K^+ /amino acid transport of neutral amino acid is strongly activated by the electrical potential, the membrane potential of mRNA-injected oocytes was modulated and K^+ -dependent leucine uptake measured. The expressed amino acid uptake was completely inhibited by a depolarising K^+ concentration (100 mM) or by the addition of 0.5 mM ouabain in the incubation medium.

The affinity of the transport for its substrates was also determined.

05-121

MECHANISM OF ACTION OF CCRF-LIKE DIURETIC PEPTIDE: STIMULATION OF TWO INTRACELLULAR SIGNAL PATHWAYS

K.W. Beyenbach, T.M. Clark, T.K. Hayes*

Section Physiology, VRT 926, Cornell University, Ithaca, NY, and Laboratory of Invertebrate Neuroendocrine Research, Texas A&M University, College Station, TX, USA

CCRF-like diuretic peptide (CCRF-DP) isolated and synthesized from *Culex* has dose-dependent effects on transepithelial voltage (V_t) in isolated perfused Malpighian tubules of *Aedes aegypti*. At low doses ($<10^{-8}$ M) CCRF-DP causes only a depolarization of V_t together with a drop in transepithelial resistance (R_t) without a change in the short-circuit current (I_{sc}). These electrophysiological effects are identical to those of leucokinin (J. Membr. Biol. 132, 63, 1993) and indicate an effect on the paracellular pathway in general, and on shunt Cl conductance in particular. At concentrations higher than 10^{-8} M CCRF-DP causes a depolarization followed by a hyperpolarization of V_t together with a drop in R_t and an increase in I_{sc} . These effects are identical to those of mosquito natriuretic peptide (NIPS 2, 171, 1987) and indicate an effect on the transcellular pathway in general, and on active transepithelial Na transport in particular. In separate experiments the effects of low doses of CCRF were duplicated with calciomycin (A23187), an ionophore of calcium. The effects of high doses of CCRF-DP were mimicked with the second messenger cyclic AMP. Thus it appears that the diuretic responses of Malpighian tubules to CCRF-DP are graded and additive through dose-dependent recruitment of different receptors and/or intracellular second messenger pathways. (Supported by NSF IBN 9220464)

05-122

MOULT CYCLE DEPENDENT EXPRESSION OF A Cl^- CHANNEL IN AN INSECT EPITHELIUMI. Watson, S. Caveney, D. Churchill¹

Department of Zoology, University of Western Ontario, London, Ontario, Canada -1 Department of Medical Physiology, Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada.

Video microscopy and whole-cell patch-clamp recording were used to monitor cell volume changes of newly-moulted epidermal (NME) cells of the flour beetle larva *Tenebrio molitor* challenged by an hyposmotic stress and to record any resulting currents. Cells reached maximal volume (14% above normal) four minutes after treatment with an hyposmotic solution (80% osmolality of normal saline) and then underwent a regulatory volume decrease (RVD) that stabilized within fourteen minutes. Application of the Cl^- channel blocker, diphenylamine-2-carboxylate (DPC, 200 μM), during hyposmotic stress blocked cellular RVD and resulted in a further volume increase (25% above normal). By varying the internal and external Cl^- concentrations, it was shown that the reversal potentials of measured swelling-activated and non-swelling currents closely followed the calculated Cl^- equilibrium potentials with a linear regression slope of 0.82. Application of DPC during current recordings reduced current strength by 60%, which was mostly reversible upon washing. These data suggest that this current is the result of the efflux of Cl^- from the epidermal cells during osmotic stress. Mid-instar cells, which are only half the volume of NME cells, have 25% of the inducible Cl^- current, implying that the number of epidermal Cl^- channels depends on the stage in the moult cycle. This osmo-sensitive Cl^- channel may be involved in the regulation of cell volume during the moult cycle.

05-124

EXTRACELLULAR MATRIX GLYCOPROTEINS IN THE MOSQUITO MIDGUT

D. C. Gare, P. F. Billingsley, N. Lofty¹

Department of Zoology, University of Aberdeen, Tillydrone Avenue, Aberdeen, AB9 2TN, Scotland, UK - 1 Department of Entomology, The University of Ain Shams, Cairo, Egypt

Insect extracellular matrices (ECM) are important but poorly understood. The molecular composition and functional roles of ECM molecules have been investigated in very few studies (for review see Lane *et al.*, 1996). Midgut epithelial cells rest on a continuous basement membrane or basal lamina (BL), which is thought to be involved in such vital cell processes as polarity, epithelial integrity, cell adhesion, selective permeability and tissue development. We have undertaken a preliminary characterization of the BL in the midgut of the mosquito, *Anopheles stephensi*. Commercially available antibodies raised against mammalian ECM molecules have been used to identify collagen IV, elastin, fibronectin and laminin. In immunofluorescence assays (IFA) all four molecules were localised to the BL of the midgut epithelial cells. Dot blots of whole gut homogenates and extracts of *An. stephensi* and *An. gambiae* cell cultures confirm the presence of the same four BL components. Western blots of cell culture extracts suggest that mosquito laminin is a polymer of three chains, as in other invertebrates and vertebrates, with subunits of approximately 70 kDa, 100 kDa and 110kDa. Collagen and fibronectin have also been visualised by SDS-PAGE and Western blots and work is continuing on the molecular characterization of these ECM molecules.

TASTE RECEPTION MECHANISMS IN *Protophormia terraenovae*: EVIDENCE OF AMILORIDE-SENSITIVE AND INSENSITIVE RECEPTOR SITES.

R. Crnjar, A. Liscia, R. Majone, P. Muron, P. Solari, I. Tomassini Barbarossa

Dipartimento di Biologia Sperimentale, Sezione di Fisiologia Generale, Università degli Studi di Cagliari

In various vertebrate species an amiloride-sensitive cation conductance has been shown to be involved in NaCl as well as sugar reception mechanisms (Cummings *et al.*, 1993; Ossebaard and Smith, 1994). Studies on salt and sugar reception in insects have been particularly intense on the gustatory apparatus of blowflies, but no information is yet available about amiloride effects on membrane receptor sites. We thus investigated the effects of amiloride on the responses to various taste stimuli in the blowfly species *Protophormia terraenovae*, with the aim of ascertaining whether an amiloride-sensitive cation conductance is also present in the chemosensory systems of insects. Electrophysiological experiments show that: (a) spike firing frequency of the "salt" cell in response to NaCl , sucrose, bovine serum albumin (BSA) and L-alanine (the C-terminal amino acid of the BSA molecule) is not influenced by the addition of amiloride (100 and 500 μM); (b) addition of amiloride does not influence the spike firing frequency of the "sugar" receptor cell in response to sucrose, but depresses the response to BSA and L-alanine; (c) the response of the "water" cell to all tested stimuli is not affected by addition of amiloride at 100 μM , but is depressed at 500 μM ; (d) pure amiloride, both at 100 and 500 μM , generally evokes a weak response from the "salt" cell. According to our results the "salt" cell seem to have no amiloride-sensitive receptor sites. Instead, the "sugar" cell apparently bears an amiloride-sensitive receptor site, distinct from the pyranose site, which appears to mediate the stimulatory effectiveness of BSA and L-alanine on this cell.

ACTIVATION OF PROTEASES IN THE HEMOLYMPH OF THE AMERICAN COCKROACH (*PERIPLANETA AMERICANA*) AS A CONSEQUENCE OF STRESSS. Liu¹, R.A. Cook², and J.E. Steele¹

¹Department of Zoology and ²Department of Biochemistry. The University of Western Ontario, London, Canada.

In the *American cockroach* the induction of stress, such as that resulting from the application of an insecticide, causes large, generally more than 25-fold, increases in the total protease activity of the hemolymph. The increase in the activity of the protease could be blocked by the application of a neck ligature prior to treatment with the insecticide.

Partial purification of the proteases was achieved by size exclusion chromatography of whole hemolymph on Sephadex G-100. All of the activity was eluted in a broad peak. The protease containing fractions were resolved using DEAE anion exchange chromatography and shown to be a mixture of at least six proteases. Two of the proteases were selected for further purification. The use of the insulin B-chain as a substrate showed that each of the proteases was clearly different in its substrate specificity.

Financial support for this research was received from Natural Sciences and Engineering Research Council of Canada (J.E.S.).

ISOLATION, BIOCHEMICAL AND FUNCTIONAL PROPERTIES OF MULTIPLE FORMS OF NADP-DEPENDENT SORBITOL DEHYDROGENASE FROM LARVAE OF SILKWORM, *BOMBYX MORI* L.

A.S.Konichev, Y.B.Filippovich, L.E.Rog
Department of Biochemistry, Moscow State
Pedagogical University, Moscow, Russia

Four forms of NADP-dependent sorbitol dehydrogenase (SDH) were purified to homogeneous state using affinity chromatography on Cibacron blue Sepharose and preparative gel electrophoresis. Two forms of enzyme from hemolymph (SDH1 and SDH2) catalyse glucose reduction to sorbitol at pH 6,3-6,5 while two other forms from midgut (SDH3 and SDH4) more active in revers reaction at pH 8,5-10,0 that correspondent to physiological pH in silkworm tissues. SDH1 and SDH2 are tetramers (Mr=30000 and 96000) while SDH3 and SDH4 are octomers (Mr=162000 and 138000). The forms of enzyme which consist of identical subunits have considerable analogy in amino acid composition. According to Km values the affinity of octomer forms to sorbitol is higher but their affinity to cofactor is lower than of tetramer forms. Kinetic properties of SDH forms are function of oligomerization.

05-128

Effect of a Trehalase Inhibitor, Validoxylamine A, on Three Species of Flies

M.Takahashi, Y.Kono, H.Kurahashi, K.Matsushita¹, Nishina¹, and Y.Kameda²

National Institute of Health, Toyama 1-23-1, Shinjuku-ku, Tokyo 162, Japan. -¹ Saitama

Medical School, Moroyama-cho, Iruma-gun, Saitama 305-04, Japan. -² School of Pharmacy, Hokuriku University, Kanazawa, Ishikawa 920-11, Japan

Effects of a trehalase inhibitor, Validoxylamine A (VAA), on the activity and haemolymph components were studied in three species of flies, *Musca domestica*, *Boettcherisca peregrina* and *Calliphora nigribarbis*. Haemolymph components were analyzed by NMR spectrometry. Overall activity of the housefly was suppressed by VAA injection (2.5 µg/fly) and 30% of them died in 2 days. The activity of the fleshfly also decreased but without death (2 µg/fly). VAA injection (5 µg/fly) acted, however, stimulatory rather than suppressively on the blowfly flight. Trehalose concentration in the haemolymph rose by VAA injection in a day to 2.6, 3.3, and 3.7 times in *M.domestica*, *B.peregrina* and *C.nigribarbis*, respectively. The trehalose accumulation seemed to be caused by inhibition of trehalose metabolism and by active synthesis of the trehalose from glucose which was not affected by VAA injection. The result that inhibition of trehalose metabolism did not evoke the reduction of the flight activity in the blowfly, suggests the use of alternative energy source in its body.

BIOCHEMICAL FEATURES OF THE TWO ADH ISOZYMES OF THE MEDFLY *CERATITIS CAPITATA*.

C. Bonvicini¹, E. Monzani², G. Valentini³, A.R. Malacrida¹ and G. Gasperi^{1,4}.

¹Department of Animal Biology, University of Pavia, Italy

²Department of General and Inorganic Chemistry, University of Pavia, Italy

³Department of Biochemistry, University of Pavia, Italy

⁴Institute of Zoology, University of Sassari, Sassari, Sardinia, Italy

The best characterised alcohol dehydrogenase (ADH; alcohol: NAD⁺ oxidoreductase; EC 1.1.1.1) from a non-Drosophilid insect is that of the Mediterranean fruit fly *Ceratitis capitata* (medfly, Diptera: Tephritidae). Like all *Drosophila* ADHs the enzymes of *C. capitata* belong to the short-chain dehydrogenase protein family, including several NAD-dependent dehydrogenases, which are characterised by a short polypeptide chain (~250 aa residues) and the absence of Zn for activity.

Biochemical-genetic studies showed that two medfly isozymes (ADH-1 and ADH-2) are encoded by two tightly linked genes (0.49 cM) on the left arm of the 2nd chromosome (Malacrida et al., 1992, *Biochem. Genet.* 30: 35-48) suggesting that the proteins are the product of gene duplication with divergence. In fact, the ADH isozymes differ in several features, such as pI, tissue localisation and development (Gasperi et al., 1992, *Biochem. Genet.* 30: 289-304). The two peptides, as determined by the nucleotide sequences of the corresponding cDNAs, show ~80% identity to each other, while they are ~40% identical to the *D. melanogaster* ADH peptide (Brognia et al., in prep.).

The catalytic properties of the two ADH isozymes have been determined on purified preparations, using primary and secondary alcohols as substrates and NAD⁺ as a coenzyme. As for the *Drosophila* enzyme, the medfly ADH-2 shows the highest activity for secondary alcohols, while the affinity of ADH-1 is highest for primary alcohols; moreover the affinity of ADH-1 for NAD⁺ is ten times higher than that of ADH-2.

Analysis of conformational changes during the interaction of each isozyme with substrates and the co-factor are in progress, using circular dichroism spectroscopy.

05-129

Effects of a Trehalase Inhibitor on the Haemolymph Energy Sources for Flight in the Locust, *Locusta migratoria*.

Y.Kono, M. Takahashi, K. Matsushita¹ E. Hasegawa^{2,3} and S. Tanaka³

National Institute of Health, Toyama 1-23-1, Shinjuku-ku, Tokyo 162, Japan. -¹ Saitama Medical School, Moroyama-cho, Iruma-gun,

Saitama 305-04, Japan. -² Ibaraki University, Faculty of Agriculture, Amimachi, Ibaraki 300-03, Japan -³ National Institute of Sericultural and Entomological Science, Ohwashi, Tsukuba 305, Japan.

Administration of validoxylamine A (VAA), a specific trehalase inhibitor, evokes various abnormality in insects. The cause of the abnormality is thought to be the stop of energy supply through the inhibition of hydrolysis of haemolymph trehalose. In *Periplaneta americana* which uses trehalose as the main fuel, the flight as well as oocyte development is inhibited by the administration. In the present paper, we examined the effect of VAA on the utilization of energy source for flight in the locust which has been known to switch the fuel from trehalose to lipids during persistent flight.

The trehalase inhibition in the flight muscle and an elevation of the haemolymph trehalose concentration occurred after the administration of VAA as observed in other insects. However, flight performance of the locust was not affected by the administration. After 1 hr of flight, the trehalose concentration in the haemolymph decreased and the lipid concentration increased in untreated locusts. In VAA treated locusts, both trehalose and lipid concentrations increased. These results may suggest that the elevation of the lipid concentration is caused by the limited supply of fuel from the inhibited trehalose metabolism, but not by the low concentration of trehalose in the haemolymph.

PROTECTIVE ROLE OF ALLOSTERIC EFFECTORS AND TREHALOSE ON THE THERMAL DENATURATION OF GLYCOGEN PHOSPHORYLASE B FROM THE FAT BODY OF LARVAL *Manduca sexta*.

J. R. Meyer-Fernandes, E. L. Arrese and M. A. Wells

Department of Biochemistry and Center for Insect Science, University of Arizona, Tucson, AZ 85721, U.S.A.

The allosteric activator, AMP, increased the thermal stability of glycogen phosphorylase b purified from the fat body of larval *Manduca sexta* in a dose-dependent manner. Thus, 20 mM AMP increased the half-time for thermal inactivation ($T_{0.5}$) by 3-fold at 60°C. IMP, which is also an allosteric activator was not able to increase the enzyme's thermal stability - IMP decreased the allosteric activation of the enzyme by AMP and also decreased the thermal protection conferred by AMP. The allosteric inhibitor ATP, which binds to the same site as AMP, was also able to increase the thermal stability of the enzyme, however with less efficiency than AMP. The substrate inorganic phosphate was able to increase the thermal stability, while the substrate glycogen was not. Organisms and cellular systems that are required to adapt to stress conditions, such as high temperature, respond by concentrating one of several organic solutes such as sugars, polyols or methylamines. Among these osmolytes are glycerol and trehalose, two polyols that are present in insect hemolymph. Glycerol at 600 mM increased 1.5-fold the $T_{0.5}$ for thermal inactivation of phosphorylase, while trehalose at the same concentration increased the $T_{0.5}$ 4-fold. Interestingly, in the presence of 20 mM AMP and 600 mM trehalose, 90 % of the enzyme activity remained after 20 minutes at 60°C. Supported by NIH grant GM 51296

05-132

IDENTIFICATION, PURIFICATION AND CHARACTERIZATION OF EPIDERMIS-ORIGIN HEMOLYMPH PROTEIN IN *GALLERIA MELLONELLA* L.

Yong-Ho Lee, Hye-Jeong Lee, Seong-Gyu Lee, Kyung-Jin Min, Hak R. Kim

Department of Biology, Korea University, Seoul, Korea

Last instar larval integument of *Galleria mellonella* L. was *in vitro* cultured in culture medium including [³⁵S]-culture medium. Epidermis-origin hemolymph protein(EDHP) was identified by electrophoresis and autoradiography and purified from the hemolymph of last instar larvae by anion exchange chromatography, gel permeation chromatography, and chromatofocusing chromatography. EDHP is composed of monomer with apparant molecular weight of 47 kDa. EDHP was immunologically confirmed to be of epidermis-origin using antibody against it. Quantitative change and presence of EDHP in other organs were also investigated.

05-131

Characterization and Purification of Lysozyme in Haemolymph of the Larvae of *Lucilia illustris*

C. S. Kang and M. Y. Kim

Department of Life Science, College of Natural Sciences, Hoseo University, Asan 337-850, Korea

Lysozyme is one component of the humoral defence system of the insects. Lysozyme in haemolymph of injured larvae of *Lucilia illustris* was identified and characterized with acidic electrophoresis and inhibition zone assay. Lytic activity against cell walls of Gram positive Bacteria shows similar effect in *Bacillus megaterium* and *Micrococcus luteus*. Lysozyme activity from injured haemolymph was higher than that of naive haemolymph. this enzyme was comparatively stable for pH and heat treatment, but heat stability was decreased drastically over 60°C. Lysozyme has been purified from injured haemolymph by reverse-phased FPLC.

05-133

STRUCTURAL CHARACTERIZATION OF THE SILKWORM HEMOLYMPH PROTEINS SEPARATED BY TWO-DIMENSIONAL GEL ELECTROPHORESIS

R.Murakami, H.Yamanouchi, H.Shinbo, M.Muraji¹, M.Kamimura, H.Hirano²

Department of Sericulture and 1 Department of Insect Genetics and Breeding, National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki, Japan - 2 Kihara Institute for Biological Research, Yokohama City University, Totsuka-ku, Yokohama, Japan

Hemolymph proteins from the 5th-instar larvae of the silkworm, *Bombyx mori*, N601 • 2 x C602 • 3 variety reared on an artificial diet were separated by two-dimensional polyacrylamide gel electrophoresis (2D-PAGE). Totally 264 protein spots were identified on the 2D-PAGE gel. These proteins were electroblotted from the gel to a polyvinylidene difluoride membrane by Western blotting and detected by Coomassie blue staining. Among them, the sequenceable amounts of 53 proteins were subjected to gas-phase sequencing with an Applied Biosystems sequencer (477A). The N-terminal amino acid sequences of 29 proteins could be determined and then compared with those of proteins compiled in the Swiss-Prot database. The N-terminal sequences of only 7 proteins were consistent with the previously determined sequences of the silkworm hemolymph proteins such as antichymotrypsin (Takagi *et al.*, 1990), antitrypsin (Narumi *et al.*, 1993), juvenile hormone-binding protein (Kurata *et al.*, 1994) and three 30K proteins (Sakai *et al.*, 1988). The sequence of a protein with Mr 59 and pI 5.3 was similar to that of the α -lactalbumin (Brew *et al.*, 1970; Addeo, 1976; MacGillivray *et al.* 1979). The 2D-PAGE patterns of proteins with Mr 30-33 kD and pI 5.3-6.5, and Mr 26-31kD and pI 5.1-5.3 considerably varied depending on the individual. The amount of the silkworm SP-1 protein with Mr 80 kD was different between female and male larvae, as described by Izumi *et al.* (1980).

05-134

A SPECIFIC PEPTIDE PRODUCED DURING ADULT DIAPAUSE OF THE LEAF BEETLE, *GASTROPHYSA ATROCYANEA*H. Tanaka, K. Suzuki, Y. Hayakawa¹, K. Sato² and M. Kurihara

Department of Bioscience and Technology, Faculty of Agriculture, Iwate University, Morioka 020, Japan - 1 The Biochemical Laboratory, The Institute of Low Temperature Science, Hokkaido University, Sapporo 060, Japan - 2 Iwate Biotechnology Research Center, Kitakami 024, Japan

Haemolymph proteins in adults of the leaf beetle, *Gastrophysa atrocyanea* have already been examined throughout the periods of pre-diapause, diapause, and post-diapause. A diapause-associated protein appeared at diapause initiation and disappeared at the end of diapause. On the contrary, an active phase-associated protein appeared at pre-diapause and post-diapause. In the present study, we paid particular attention to low molecular weight of proteins of the leaf beetle. As a result, a peptide appeared at diapause and disappeared at pre- and post-diapause. The mol. wt of this peptide was about 4.5 kDa. To isolate this specific peptide, we used the methods of disc preparative SDS-PAGE, gel exclusion HPLC and reversed HPLC. Some properties of this diapause-specific peptide were investigated to understand control mechanism of adult diapause. Then the N-terminal amino acids sequence for the first 34 residues was determined.

05-136

CONCENTRATION OF TREHALOSE AND ALANINE IN HAEMOLYMPH OF OVERWINTERING LARVA, *ENOSIMA LEUCOTAENIELLA* (R.) (LEPIDOPTERA: PYRALIDAE)M. Goto¹, K. Suzuki, M. Sakai²

1 Department Bioprocess Engineering, Yamagata University, Tsuruoka Yamagata, Japan - 2 Department Applied Bioscience and Technology, Iwate University, Morioka, Japan

Diapausing larvae collected in October were incubated for 30 days at seven different temperatures (0 to 30°C). Trehalose which is dominant substance in haemolymph was high level at lower temperature and reached a maximum at 5°C. Glycogen contents in body were almost inversely proportional to trehalose concentration and reached a minimum at 0°C. More than 29 kinds of free amino acids were detected in haemolymph by using high speed amino acid analyzer. The concentration of alanine in the haemolymph of the overwintering larvae which had experienced the regimen of low temperature at 0°C was 1.8 fold high level compared with the larvae having experienced the regimen at 5°C. From September to January, trehalose concentration increased with decreasing glycogen, however, in February, both trehalose and glycogen level decreased. These results suggest that the high concentration of alanine might make an important role in glycogen decrease at low temperature below 5°C.

05-135

EFFECT OF CHILLING PERIOD ON PUPAL DIAPAUSE TERMINATION OF FLESH FLY, *BOETTCHERISCA PEREGRINA*A. Moribayashi, J. D. Wells, T. Hayashi, H. Kurahashi, N. Agui
Department of Medical Entomology, National Institute of Health, Tokyo, Japan

By using diapausing pupae of the flesh fly, *Boettcherisca peregrina*, we examined effect of chilling which may provide clues to the termination of diapause and developmental fate to adult. The fly enters to diapause at pupal stage under a short day condition (11L:13D) and low temperature at 20°C. Diapausing pupae were kept for 2 months at 20°C and then held at 4°C (chill treatment) for various duration between zero and 48 weeks before transfer to adult-developing condition at 27°C. 70–89% adult emergence occurred in pupae chilled for zero or 3–15 weeks, with the highest rate observed in those chilled 12 weeks. Relatively low emergence occurred in pupae chilled 1–2 or ≥ 20 weeks.

Distribution of adult-emergence days was determined for pupae with and without chilling. Pupae given no chilling emerged during a period of 59 days after transfer to 27°C. Pupae kept at 4°C for 12 weeks emerged during a narrow range of 23 days. All pupae that failed to emerge were dissected and confirmed to be dead. From these results we discuss about a relationship between chilling and diapause termination during pupal-adult development

05-137

DIFFERENCES OF COLD-HARDINESS BETWEEN THE SILVER Y MOTH, *AUTOGRAPHA GAMMA* (L.) AND THE ASIATIC COMMON LOOPER, *A. NIGRISIGNA* (WALKER).

J. Kaneko

Cold-hardiness of the silver Y moth, *Autographa gamma* on the stage of eggs, larvae, and pupae was compared with that of the Asiatic common looper, *A. nigrisigna* at the condition of 0°C, 100% R.H.

In each stage, both species individuals nearly all died after 10 to 30 days chilling without conditioning (10°C for 1 day and 5°C for 5 days). However, conditioned individuals survived more chilling days in both species, and this change was remarkable in the silver Y moth. Conditioned third instar larvae of silver Y moth survived 120 days chilling at rate of 1.4%. Contrary to this, none of conditioned individuals of *A. nigrisigna* survived 90 days chilling.

05-138

ICE-NUCLEATING ACTIVE AGENTS IN LARVAE OF THE RICE STEM BORER, *CHILO SUPPRESSALIS* WALKER (LEPIDOPTERA: PYRALIDAE)H. Tsumuki, M. Hirai¹

Research Institute for Bioresources, Okayama University, Chuo Kurashiki 710, Japan -1 School of Medicine, Mie University, Edobashi Tsu 514, Japan

Hibernating larva of the rice stem borer, *Chilo suppressalis* was a freezing tolerant insect. The larvae produced ice-nucleating active agents (INAs) in the muscle during hibernation. The production of the endogenous INAs was accelerated by low temperatures. They were sensitive to protease, stable at at least 50 °C for 5 min, and active over a broad pH range and after delipidation treatments. Consequently their chemical properties are more similar to those of the exogenous INAs of *Fusarium moniliforme* var. *subglutinans* isolated from the gut of the non-diapausing larvae rather than those of bacteria.

After differential centrifugation of the muscle homogenate, the crystallization temperature of the microsomal fraction was the highest among the all fractions. A small part of the muscle could raise the crystallization temperature of the haemolymph. These results suggest that the endogenous INAs are present on the outside of the muscle cell membrane and induce extracellular freezing by the same mechanism as that in other insects which possess INAs in the haemolymph.

05-140

RELATIONSHIP BETWEEN PTERIDINE METABOLISM AND SEASONAL COLOR DIMORPHISM IN THE SCORPION FLY, *PANORPA JAPONICA* THUNBERG

M. Nakagoshi, S. Takikawa

Biological Laboratory, Kitasato University, Sagamihara Kanagawa, Japan

The scorpion fly, *Panorpa japonica*, displays a seasonal color dimorphism by changing from black in spring to yellow in summer in the adult state.

The yellow pigment was identified as sepiapterin, while the black one was proved to be melanin. The quantities of these pigments in the integument of the mature fly varied depending upon the color dimorphism of the insect.

The combination of the morphological and biochemical approaches shows that sepiapterin is characteristically located at the pigment granules in the integument of the insect.

Various pteridines, neopterin, biopterin, isoxanthopterin and 7-oxo-biopterin, were also isolated in the adult scorpion fly besides sepiapterin.

The content of various pteridines and the activities of various enzyme related to pteridine biosynthesis (GTP-cyclohydrolase I, 6-pyruvoyl-tetrahydropterin synthase and sepiapterin reductase) were measured at several stages after emergence of both yellow type fly and black one.

The results suggested that GTP-cyclohydrolase I is a key enzyme in the relationship between pteridine metabolism and seasonal color dimorphism.

05-139

BLUE PIGMENT BINDING PROTEINS FROM CABBAGE WHITEBUTTERFLY, *ARTOGEIA RARPAE* (LEPIDOPTERA)

C. Y. Yun, S. H. Nam

Department of Biology, Taejon University, Taejon, Korea

Three blue pigment binding proteins (BPs) were identified from the prepupal haemolymph by native polyacrylamide gel electrophoresis using Prep Cell. Two BPs were purified from the larval haemolymph of *Artogeia rapae*, and the physicochemical properties and changes during development were examined.

During last instar larval and prepupal stages, BP1 was maintained highly in haemolymph but disappeared after prepupal stage, whereas BP2 increased drastically in the prepupal haemolymph and showed maximum in pupal stage. And minute amounts of BP3 could be detected in the prepupal stage.

Antiserum against BP1 did not show cross-reactivity with BP2 in immunodiffusion test. BP1 was a major protein of extract from wing, and egg contained both of BP1 and BP2. BP1 is believed to function as storage proteins and insect coloration.

05-141

PROTEIN METABOLISM IN HONEY BEE NURSES

H. Kropiunigg, K. Crailsheim and B. Leonhard

Abteilung für Stoffwechselphysiologie, Institut für Zoologie an der Karl Franzens Universität, A-8010 Graz, Universitätsplatz 2, Austria.

When is a bee able to nurse? To determine this ability within the polyethism schedule of honey bees we injected C14-phenylalanine as a tracer into the haemolymph of differently aged bees. Then we estimated the amount of incorporation into protein of the abdomen, of the thorax and of the head, the latter mainly containing the hypopharyngeal glands (brood food glands). We recorded the behaviour of sister-bees of the same age in an observation hive. Brood nursing was defined when a bee inserted with her head into a broodcell for 1 to 20 seconds. Donating food by trophallaxis was defined when a bee held her tongue between the mandibles of the observed bee for more than one second.

Two hours after injection, in almost all investigated bees the greatest amount of phenylalanine was incorporated into the abdominal protein, whereas the smallest amount was measured in the thoraces.

We found brood nursing activity until an age of somewhat more than 2 weeks, but protein synthesis in the head could remain high until the 4th week. In different series of experiments the moment of maximum incorporation activity in the hypopharyngeal glands could vary. At the very end of their life this activity always decreased.

The fact that bees can synthesize so much protein even at an age when they do no longer feed brood could be explained by the synthesis of enzymes (Knecht and Kaatz, 1990, *Apidologie* **21**:457-468) and might indicate the synthesis of proteinaceous food that is given to other very young bees or foraging bees (Crailsheim, 1992, *J. Comp. Physiol. B* **162**: 681-689). Food was seen to be donated more often during this later period.

05-142

AMINO ACID METABOLISM IN HONEY BEE WORKERS AND DRONES

B. Berger, K. Crailsheim, B. Leonhard

Abteilung für Stoffwechselphysiologie, Institut für Zoologie an der Karl-Franzens-Universität, A-8010 Graz, Universitätsplatz 2, Austria.

Amino acids labelled with ^{14}C were injected into the haemolymph of various aged honey bee workers and drones with known amino acid concentrations. For 4 hours the bees were free to move and feed in a 20 ml translucent vial. Air was pumped through this vial and bubbled through Carbosorb (a CO_2 absorber from Packard). Four hours later, we determined ^{14}C incorporated into protein, remaining in the haemolymph, and absorbed in Carbosorb.

Compared to phenylalanine and leucine, proline was the predominant amino acid in the haemolymph (1:40 -1:20) and was subjected to oxidative metabolism even more pronounced. Dimensionally similar results could be seen for both sexes and all age classes investigated.

The incorporation of the injected amino acids into protein was generally fastest in young drones and dimensionally similar for all 3 amino acids. The greatest ratio was observed in 5 day old workers between leucine and proline; it was 1:5.

More than 50% of all amino acids in the haemolymph was proline. Although this amino acid plays a minor role in the total energy balance of bees compared to carbohydrates, its relatively high oxidative metabolism indicates its importance and outstanding role.

Supported by the Austrian Science Foundation.

MOLECULAR CLONING OF cDNA FOR HYPOPHARYNGEAL GLAND PROTEINS, AND A GENE EXPRESSING SELECTIVELY IN THE MUSHROOM BODY OF THE WORKER HONEYBEE (*APIS MELLIFERA* L.)

T. Kubo, K. Ohashi, H. Takeuchi, M. Sawata, and S. Natori

Faculty of Pharmaceutical Sciences, University of Tokyo, Bunkyo-ku, Tokyo, Japan

Age-dependent role change is a characteristic feature of the honeybee, *Apis mellifera* L. society. The role of worker bees changes with age; young workers nurse brood by secreting and feeding bee milk, whereas older ones forage for nectar and process it into honey. Physiological changes occur in some organs according to the age and/or role change of the worker bee. We showed that three major proteins synthesized specifically in the hypopharyngeal gland of the nursebee are bee-milk proteins, while a major protein synthesized in the forager-bee gland is an α -glucosidase, indicating that the gland has two distinct differentiation state depending on the age-dependent role change (1).

Here, we isolated and analyzed cDNAs for these proteins. The results indicated that three bee-milk proteins share high sequence similarity with each other and those of RJP57-1 and RJP57-2 that are reported by Hanes and Simuth (2), indicating that they belong to a protein family. Honeybee α -glucosidase was found to share 70 % sequence similarity with possible *Drosophila* maltase gene product.

To investigate the molecular basis to cooperate the physiological conditions and the neural network of the brain of the worker bee, we searched for genes expressing selectively in the mushroom body of the worker bee brain by Differential Display as mushroom body is supposed to be a center to integrate sensory and motor neurons. One clone pMB5 was subcloned and found to express specifically in the large-type Kenyon cells of the mushroom body, indicating that the function of the gene is needed for a specific type of Kenyon cells.

PURIFICATION OF ENDO- β -1,4 GLUCANASE COMPONENTS FROM A LOWER TERMITE *RETICULITERMES SPERATUS*H. Watanabe, M. Nakamura, G. Tokuda¹, I. Yamaoka¹, and H. NodaNational Institute of Sericultural and Entomological Science, Tsukuba, Owashi, 305 Japan - ¹Faculty of Science, Yamaguchi University, Yamaguchi, Yamaguchi 753-01, Japan.

Two endogenous endo- β -1,4-glucanase components (YEG1 and YEG2) were purified and characterised from the lower termite, *R. speratus* using Superdex 75 molecular filtration and hydroxylapatite chromatography. Using a whole body extract prepared from workers and soldiers, one β -glucosidase and one endo- β -1,4-glucanase peak were obtained on chromatography with Superdex 75 with ammonium acetate buffer (0.3 M, pH 5.0). The endo- β -1,4-glucanase peak separated into two components (YEG1 and YEG2) on hydroxylapatite chromatography using a linear gradient of potassium phosphate (2-500 mM, pH 5.3). YEG1 and YEG2 had M_r of 45,900 and 45,000, respectively, on SDS-PAGE. Both components had an optimal pH of 6.0, and an optimal temperature of 50°C and were stable at 40°C for at least 30 min. YEG1 and YEG2 showed high activity against sodium carboxymethylcellulose (CMC), 73.6 units/mg protein for YEG1 and 83.4 units/mg protein for YEG2. YEG1 did not hydrolyse cellotetraose or cellotriose, while YEG2 hydrolysed cellotetraose and cellotriose. Both YEG1 and YEG2 hydrolysed cellopentaose to cellotriose and cellobiose, but neither component hydrolysed cellobiose. Cellobiose was formed from crystalline cellulose (Sigmacell Type 20) by both YEG1 and YEG2. The major product formed by YEG1 and YEG2 from all substrates was cellobiose with trace amounts of glucose. The K_m values for YEG1 and YEG2 against cellopentaose were 0.7 mM and 4.1 mM, respectively and against CMC, 1.83 mg/ml and 1.48 mg/ml, respectively. The K_m values of YEG2 on cellotetraose and cellotriose were 6.1 and 22.7 mM, respectively. Polyclonal mouse anti-serum was made against YEG2 using pure YEG2. It cross-reacted with YEG1 to the same extent as it did to YEG2, suggesting a common origin for both components. Western blotting and immunohistochemistry, using this anti-serum showed the presence of YEG1 and YEG2 in the salivary glands, but their absence from the midgut epithelium. It is proposed that the salivary glands are the major site of secretion of cellulase activity in *R. speratus*.

05-145

BIOCHEMICAL AND PHYSIOLOGICAL PARAMETERS OF *COPTOTERMES ACINACIFORMIS* (FROGGATT) IN LABORATORY AND FIELD COLONIESN. Lo¹, M. Slaytor¹ and R. H. Eldridge²¹Department of Biochemistry, The University of Sydney, Sydney, Australia - ²State Forests of NSW Research Division, West Pennant Hills, N.S.W., Australia

Biochemical and physiological parameters of *C. acinaciformis* were measured to test the validity of using termites maintained in an accelerated field simulator (AFS) rather than termites in the field for wood preservation studies. It is known that termites brought from disrupted field colonies into the laboratory undergo rapid changes in nitrogen metabolism. The reasons for these changes are not understood, but may be related to the disruption of the social structure when the nest is destroyed.

In the AFS, an intact nest of *C. acinaciformis* from the centre of a tree trunk was placed in a nest tank connected to a feeding tank and a soil-based foraging area. For comparative purposes, termites were collected as needed from nearby field colonies. There were no significant differences between the two groups of termites in respiratory activity, cellulase activity, uric acid content, total nitrogen content or nitrogen fixing ability. In contrast, termites taken from the field or the AFS and stored in nest material in the laboratory show a characteristic decline in nitrogen fixation levels as well as an increase in uric acid storage. These data suggest that termites are metabolically unchanged when maintained in the AFS and hence can justifiably be used in assessing wood susceptibility to termite attack.

05-146

STAGE SPECIFIC EXPRESSION OF FIBROINASE ACTIVITY IN THE SILK GLAND OF THE SILKWORM, *BOMBYX MORI*

M. Sumida, A. Yura

Department of Applied Biology, Kyoto Institute of Technology, Kyoto Japan

Fibroinase which hydrolyzes liquid fibroin and sericin was purified from the supernatant fraction of silk gland homogenate at stage D2 of the fourth molt larvae in the silkworm, *Bombyx mori*. It is a cysteine proteinase similar in kinetic properties to cathepsin L with a subunit molecular weight of 34kDa. It hydrolyzes liquid fibroin like an endopeptidase. Based on this catalytic property, an assay method of fibroinase using liquid fibroin as a natural substrate was refined and a tentative enzyme unit was defined. Developmental changes in fibroinase activity in the silk gland were determined by the modified assay method. A synthetic substrate for cathepsin L activity was also used. Two activity peaks in terms of g wet weight of tissue were observed, the one at stage D2 of the fourth molt larvae and another at the time of end of spinning. A similar profile of activity was observed using a synthetic substrate for cathepsin L activity. Fibroinase is conceivable to be a new molecular marker for the study of stage specific function of silk gland tissue. Since the silk gland does not degenerate in the fourth molt larvae but is programmed to degenerate in the early pupae in the presence of fibroinase activity in the tissue at both developmental stages, by differential screening of other tissue proteinases using fibroinase as a reference proteinase, mechanisms of tissue degeneration in the silk gland is highly likely to be elucidated.

05-148

PRELIMINARY CHARACTERIZATION OF AN ENTOMOTOXIC PROTEIN PRODUCED *IN VITRO* BY THE *STEINERNEMA CARPOCAPSAE* - *XENORHABDUS NEMATOPHILUS* COMPLEX.

A. F. Palha, N. Simões & P. Oliveira

Departamento de Biologia, Universidade dos Açores, Ponta Delgada, Portugal

An entomotoxic protein was obtained by the incubation *in vitro* of the *Steinernema carpocapsae* - *Xenorhabdus nematophilus* complex. A partial characterization of the entomotoxic fractions proved them to be thermolabile protein, with activity above pH 5 and under pH 10. The entomotoxic protein was partially purified until a specific activity of 3795AT/mg protein, with a purification factor of 113 and a yield of 2%. In reducing PAGE/SDS, the electrophoretic analysis of the entomotoxic fraction revealed several protein bands and the relative molecular weight of a band supposed to be the responsible for the entomotoxic activity was estimated to be approximately 43 KDa. The hemocoelic injection into *Galleria mellonella* larvae of the toxic aliquots caused the paralysis of the treated larvae, followed by tetanization and death within 24 hours.

05-147

RIBOSOMAL PROTEIN L5 cDNA OF *BOMBYX MORI*: SEQUENCE AND TRANSCRIPTION

C. Yang, F. Sehnal

Institute of Entomology, Academy of Sciences, and Faculty of Biological Sciences, University of South Bohemia, České Budějovice, Czech Republic

Ribosomal protein L5 is associated with eukaryotic 5S rRNA, forming a precursor complex of the 60S ribosome subunit. The sequence of L5 has been established in molecular biology studies in yeast, rice, a nematode, and several vertebrates. We now report on isolation of a 1 kb cDNA encoding L5 of *Bombyx mori*. Nucleotides of the coding region and the deduced amino acids exhibit over 65% and 75% homologies with the respective sequences of the vertebrate L5 (nucleotides and amino acids shared by *Xenopus*, chicken, rat and man were considered), progressively lower homologies were found with the nematode, plant and yeast L5. *Bombyx* contains a single copy of the L5 gene that is constitutively expressed in all examined cell types but the level of expression seems to reflect the intensity of proteosynthesis. The highest amount of L5 mRNA occurs in the silk glands. It is virtually constant throughout the penultimate and last larval instars but drops sharply after the cocoon spinning. Interestingly, the degenerating pupal silk glands retain a small amount of the L5 transcript.

05-149

RESPONSES OF CHESTNUT MOTHS TO SEMIOCHEMICALS: ELECTROPHYSIOLOGY AND FIELD TESTS

A. De Cristofaro, G. Rotundo, C.J. Den Otter

Dipartimento di Scienze Animali, Vegetali e dell'Ambiente, Università del Molise, Campobasso, Italy

Sensory Physiology Group, Department of Animal Physiology, University of Groningen, Haren, The Netherlands

Electrophysiological responses of males and females *Pammene fasciana* (L.), *Cydia fagiglandana* (Zeller) and *C. splendana* (Hübner) on stimulation with tortricid sex attractants and with volatiles from chestnut leaves are reported. Field tests were carried out in different chestnut areas of Southern Italy.

Z8-12:Ac elicited the higher EAG response for *P. fasciana*. Traps loaded with this compound catch high number of *P. fasciana*; their attractant power and selectivity are improved adding Z8-12:OH.

EAG recordings showed that E8E10-12:Ac and its isomers (Z,E; E,Z; Z,Z) highly stimulated the antennae of *C. fagiglandana* and *C. splendana*. Dose-response curves were almost identical for males of both species. Females antennae were also stimulated and EAGs were up to 50 times lower. Field tests showed that traps baited with E8E10-12:Ac or Z8E10-12:Ac catch high and low number of males of *C. fagiglandana* and *C. splendana*, respectively. Mixtures of E8E10-12:Ac with E8E10-12:OH improved the trap selectivity to *C. fagiglandana*. *Cydia* species are also able to smell Z8-12:Ac. Traps loaded with mixtures of E8E10-12:Ac with Z8-12:Ac do not catch males of the three species.

Preliminary single-cell recordings (Den Otter *et al.*, *in press*) from *C. fagiglandana* males suggested that E8E10-12:Ac activated cells with medium-sized spikes, E8E10-12:OH and Z8-12:Ac these same cells and cells with large spikes and small spikes, respectively. Some chestnut volatiles activated cells with the medium-sized spikes only.

05-150

ELECTROANTENNOGRAM RESPONSES OF THE RICE BROWN PLANT HOPPER *NILAPARVATA LUGENS* TO PLANT VOLATILE COMPOUNDSY.N. Youn, L.J. Goodman¹

Department of Agricultural Biology, College of Agriculture, Chungnam National University, Taejeon, 305-764, Korea - 1
 Department of Biological Sciences, Queen Mary & Westfield College, University of London, Mile End Road, London, E1 4NS, England

Electroantennogram recordings were made from the plaque organ receptors of the rice brown plant hopper, *Nilaparvata lugens*. The receptors of the distal plaque organ of male and female hoppers responded to the air from above chopped rice plant although females gave a larger response. Female hoppers, tested with 27 plant volatiles, gave dose-related responses to 16 of the compounds, including a range of green leaf volatiles. The aliphatic aldehydes hexanal and *trans*-2-hexenal elicited a larger response than the green leaf alcohols tested. Acetophenone, benzaldehyde, ethyl and methyl benzoate and amyl and isoamyl acetate were among the most effective of the remaining compounds tested. Receptor recovery times for dose-response related compounds were generally quite similar with the exception of *trans*-2-hexenal which required exceptionally long recovery periods. A comparison of the dose-related response of 16 compounds made up in paraffin oils and pentane showed that receptors appeared considerably more sensitive to the compounds when the highly volatile solvent pentane was used. Both female and male hoppers responded to the air from above male hoppers. Male hoppers were sensitive to the air above rice leaf sheath containing hopper eggs.

INSECT PHYSIOLOGY SERVING SOCIETY IN THE 21st. CENTURY

G. Michael Chippendale

Dept. of Entomology, 1-87 Agriculture Bldg.,
 University of Missouri, Columbia, MO 65211, USA

The current age of biology has a dominant place for insect physiology. This talk will present the historical context for this prediction, and provide examples of growth areas for insect physiology in the 21st. Century. The 20th. Century saw a tremendous increase in our knowledge about how insects function, but we are lacking depth and breadth in our understanding of insect life processes. However, this situation is changing rapidly with developments in instrumentation, computer technology, and molecular biology making insects increasingly amenable to physiological and biochemical study. Advances in insect biochemistry, genetics, and molecular biology are providing the foundation for technological innovations in the genetic engineering of plants resistant to insects and the development of new biorational control procedures. Advances in physiological ecology in such areas as the mass rearing of natural enemies, molecular systematics, and seasonal development and behavior are providing the foundation for biologically intensive integrated pest management as part of holistic resource management. Furthermore, biologists are realizing the potential of insects as model animal species for physiological and biochemical studies because of their ease of rearing in large numbers, relatively low maintenance costs, and short life cycles.

05-152

Juvenile hormone metabolic activity in fat body from *Pseudoplusia includens* injected with *Microplitis demolitor* calyx fluid.

B.A. Dover, Dept. Entomology, Kansas State Univ.,
 Manhattan, KS 66506, USA.

M.R. Strand, Dept. Entomology, Univ. Wisconsin,
 Madison, WI 53706, USA.

Calyx fluid from the braconid parasitoid *Microplitis demolitor* suppresses host hemolymph JH esterase activity when injected into last-stadium *Pseudoplusia includens*. Evidence suggests that the effect of *M. demolitor* calyx fluid on host JH esterase activity is not due to a humoral factor. We will measure JH esterase levels and JH esterase and epoxidase activity in tissues from control and calyx fluid-injected *P. includens*.

05-153

ANALYSIS OF PARASITISM SPECIFIC PROTEINS IN THE PARASITOID-HOST SYSTEM *CHELONUS INANITUS*-*SPODOPTERA LITTORALIS*

A. Hochuli and B. Lanzrein

Division of Developmental Biology, Institute of Zoology, University of Berne,
 Berne, Switzerland

Parasitism by the egg-larval parasitoid *C. inanitus* induces in its host *S. littoralis* the precocious onset of metamorphosis in the 5th stadium while nonparasitized larvae pass through 6 stadia (Grossniklaus et al., 1994, *Invert. Reprod. Develop.* 25, 143-158). We could recently show that the parasitoid larva plays a key role in inducing precocious metamorphosis (Pfister-Wilhelm and Lanzrein, *Arch. Insect Biochem. Physiol.*, in press). In order to investigate a potential role of parasitoid-made proteins in this process, we produced antibodies against proteins released by parasitoid larvae in vitro. With these antibodies we analyzed the presence and persistence of parasitoid-made proteins in haemolymph of host larvae. A protein of approx. 200 kD was observable from the 3rd larval instar onwards and three others appeared in the transition from the 4th to the 5th larval instar. By parasitoid removal experiments the persistence of these proteins was investigated and correlated with the developmental fate of such parasitoid-deprived host larvae. We also collected and concentrated medium in which parasitoids had been cultured and injected it to study the effect on development and metamorphosis of recipient larvae.

05-154

POLYDNAVIRUS DNA OF THE BRACONID WASP *CHELONUS INANITUS* IS INTEGRATED INTO THE WASP GENOME AND EXCISED IN THE FEMALES AT LATE STAGES OF PUPAL-ADULT DEVELOPMENT

A. Gruber, P. Heiniger, D. Schümperli, B. Lanzrein

Division of Developmental Biology, Institute of Zoology, University of Berne, Berne, Switzerland

The polydnavirus (PDV) of the braconid wasp *C. inanitus* has been characterized and the genome was shown to consist of double stranded circular DNA molecules of sizes between 7-31 kbp (Albrecht et al., 1994, J. Gen. Virol. 75, p. 3353-3363). We have investigated whether viral DNA is integrated in the wasp genome as shown for the ichneumonid wasp *Campoletis sonorensis* (Fleming and Summers 1991, Proc. Nat. Acad. Sci. USA, 88, p. 9770-9774). We screened a *C. inanitus* adult male genomic library with a fragment of a 12 kbp viral segment and obtained a positive clone in which viral and flanking genomic sequences were analyzed. This is the first direct demonstration of integration of PDV DNA in a braconid wasp. By the use of PCR primers which distinguish between the integrated and the excised and circularized form of viral DNA, we show that the integrated form is present in both sexes at all developmental stages and excision and circularization of viral DNA begins in females at late stages of pupal-adult development.

05-156

ENDOCRINE CHANGES ASSOCIATED WITH THE POLYDNAVIRUS/VENOM INDUCED DEVELOPMENTAL ARREST IN THE PARASITOID-HOST SYSTEM *CHELONUS INANITUS*-*SPODOPTERA LITTORALIS*

C. Grossniklaus-Bürgin¹, K. Treiblmayr², B. Lackner², V. Meyer³, B. Lanzrein¹

¹ Division of Developmental Biology, Institute of Zoology, University of Berne, Berne, Switzerland - ² Institute of Zoology, University of Salzburg, Salzburg, Austria - ³ Chemical Institute, University of Berne, Switzerland

The presence of polydnavirus (PDV) and venom of the egg-larval parasitoid *C. inanitus* has been shown to induce developmental arrest in the prepupal stage of *S. littoralis* (Soller and Lanzrein, J. Insect Physiol., in press). We have compared various endocrine parameters between nonparasitized last instar larvae and last instar larvae parasitized by X-ray irradiated wasps. Such wasps oviposit normally into *S. littoralis* eggs and inject PDV and venom. However, the parasitoid eggs are infertile and no parasitoid develops. In X-ray parasitized larvae we observed, as compared to nonparasitized larvae, a slight alteration of juvenile hormone (JH) titres in the early feeding stage, a delay and depression in the post-wandering JH esterase and delayed and desynchronized increases in prepupal JHs and ecdysteroids. Only minor differences in ecdysone metabolism were observed, and in vitro incubation of prothoracic glands indicates that the biosynthesis of ecdysone is suppressed in X-ray parasitized larvae at the cell formation stage.

05-155

INTERFERENCE OF THE PARASITOID *CHELONUS INANITUS* WITH THE JUVENILE HORMONE SYSTEM OF THE HOST *SPODOPTERA LITTORALIS*

R. Pfister-Wilhelm¹, K. Treiblmayr², B. Lackner², B. Lanzrein¹

¹ Division of Developmental Biology, Institute of Zoology, University of Berne, Berne, Switzerland - ² Institute of Zoology, University of Salzburg, Salzburg, Austria

The egg-larval parasitoid *C. inanitus* (Braconidae) induces in its host *Spodoptera littoralis* (Noctuidae) the precocious onset of metamorphosis, i.e. parasitized larvae enter metamorphosis in the 5th stadium and non-parasitized larvae do so in the 6th stadium. We could recently show by parasitoid removal and transplantation experiments that the parasitoid larva plays a key role in manipulating host metamorphosis (Pfister-Wilhelm and Lanzrein, Arch. Insect Biochem. Physiol. in press). We show here data on effects of parasitoid implantation on the *c. allata* activity and on the juvenile hormone (JH) titres of recipient larvae and correlate these with the developmental fate of such larvae.

05-157

HOST REGULATION EFFECTS OF OVARY EXTRACTS AND VENOM OF *APHIDIUS ERVI* HALIDAY (HYMENOPTERA, BRACONIDAE)

M. C. Digilio, F. Pennacchio¹, E. Tremblay

Dipartimento di Entomologia e Zoologia Agraria, Università di Napoli "Federico II", Portici (NA), Italy - ¹ Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy

The aphid parasitoid *Aphidius ervi* Haliday regulates development, metabolism and reproduction of its host *Acyrtosiphon pisum* (Harris) (Pennacchio et al., 1995, Arch. Insect Biochem. Physiol., 30, 351-367). The ovary development is strongly affected by the parasitoid. Parasitism of pea aphid 1st instars results in a complete inhibition of ovary development associated to a subsequent developmental arrest of the host, which is unable to reach the adult stage and dies as 4th instar. Arrested hosts show a reduced titer of total ecdysteroids, compared to synchronous nonparasitized controls. These parasitoid-induced alterations were in part duplicated by injecting into *A. pisum* 4th instars nonphysiological doses of venom gland and ovary extracts from *A. ervi*. The most evident symptom after injection was the arrest of the development and death as 4th instar, while saline injected controls usually attained the adult stage and reproduced. Electron microscopy observations did not show the presence of viral particles both in the ovary and venom gland. The highest rate of developmentally arrested aphids was obtained by injecting a mixture of ovary and venom gland extracts (1:1), while separate injections of these two extracts were significantly less effective and induced similar results. Heat treatment and protease digestion of the combined extracts both eliminated host developmental arrest, suggesting that a protein could be the host regulatory factor involved. SDS-PAGE analysis of ovary and venom extracts showed that they have a similar electrophoretic pattern. Further studies are in progress to isolate the active component/s.

05-158

DEVELOPMENTAL EFFECTS AND EXPRESSION OF POLYDNA VIRUS GENES FROM *MICROPLITIS CROCEIPES* (CRESSON) IN PERMISSIVE AND NON-PERMISSIVE HOSTS (HYMENOPTERA: BRACONIDAE - LEPIDOPTERA: NOCTUIDAE AND PYRALIDAE)

S.M. Ferkovich, S.G. Miller, J. Maruniak¹

U.S. Department of Agriculture, Agricultural Research Service, Insect Attractants, Basic Biology and Behavior Research Laboratory, Gainesville, Florida USA - ¹ Department of Entomology and Nematology, University of Florida, Gainesville, Florida USA

In the natural host parasitoid association, *Helicoverpa zea* (Boddie) and *Microplitis croceipes* (Cresson), and in association with a semi-permissive host *Galleria mellonella* (L.), injections of calyx fluid and venom differentially affected growth and development of the hosts, however in a non-permissive host, *Spodoptera exigua* (Hübner), injections of calyx fluid and venom had a minimal effect. Expression of polydnavirus genes from *M. croceipes* in the three host species is being examined.

05-160

INFLUENCE OF PARASITIZATION BY THE SOLITARY PARASITOID *GLYPTAPANTELES PORTHETRIAE* ON THE DEVELOPMENT AND JUVENILE HORMONE DEGRADATION OF ITS HOST *LYMANTRIA DISPAR* (HYMENOPTERA: BRACONIDAE - LEPIDOPTERA: LYMANTRIIDAE)

C. Nussbaumer, A. Schopf, B.D. Hammock¹

Universitaet fuer Bodenkultur, Institut fuer Forstentomologie, Vienna, Austria - ¹ University of California, Department of Entomology and Environmental Toxicology, Davis, CA USA

Although the solitary endoparasitic braconid *Glyptapanteles porthetriae* (Muesebeck) is an abundant, natural controlling agent of the gypsy moth throughout its native range only little is known about its development.

Under natural conditions *G. porthetriae* attacks mainly first instar gypsy moth larvae. Fresh weight of the parasitized larvae in the third instar is significantly lower than the fresh weight of unparasitized control larvae of the same stage. During the late third instar the host stops feeding and the parasitoid emerges several days later. By that time control larvae have molted into the fourth instar. Larval development and molting is depending on the juvenile hormone titer (JH) in the hemolymph of the host. JH in the blood of gypsy moth was shown to be degraded by only one enzyme, the juvenile hormone esterase (JHE). Two peaks of JHE activity occurred in third instar control larvae, one at the beginning and a second one at the end of the instar. In the hemolymph of parasitized larvae only the first peak was found. Later in the third instar hardly any JHE activity was detected. This blocking of the JHE activity by the parasitoid might be the reason for a high JH titer in the host's hemolymph which subsequently causes disruption of development. Premature death of the host results in a significant decrease in feeding damage compared to the damage caused on oak by normally developing gypsy moth larvae.

05-159

CHANGES IN JUVENILE HORMONE ESTERASE ACTIVITY AND ECDYSTEROID TITER IN LARVAE OF THE SPRUCE BUDWORM, *CHORISTONEURA FUMIFERANA*, PARASITIZED BY THE WASP *ENYTUS MONTANUS*.

M. Cusson, M. Laforge¹, D. Doucet², C. Cloutier¹, D.B. Stoltz³

Laurentian Forestry Centre, Canadian Forest Service-Quebec, Sainte-Foy (Qc), Canada - ¹Département de biologie, Université Laval, Sainte-Foy (Qc), Canada - ²Department of Biology, Queen's University, Kingston (Ont.), Canada - ³Department of Microbiology and Immunology, Dalhousie University, Halifax (N.S.), Canada.

Last-instar *Choristoneura fumiferana* larvae parasitized by *Enytus montanus* early in the stadium display retarded development and fail to initiate metamorphosis. Similarly, injection of the wasp's calyx fluid (CF) into healthy caterpillars induces a dose-dependent delay in pupation, which can be abolished by prior treatment of CF with UV and the DNA cross-linker psoralen. These results suggest that the wasp's polydnavirus is the factor responsible for the observed developmental disruptions.

In an effort to identify the physiological processes that are perturbed by *E. montanus* CF, we examined the effects of parasitism and injection of CF on host plasma juvenile hormone esterase (JHE) activity and ecdysteroid titers in last-instar budworms. Under our experimental conditions, control larvae displayed only one peak of JHE activity (~ 30 nmol JH III/min/ml), which occurred on day 4 of the last stadium. In saline-injected animals, a similar peak was observed, but on day 5. In larvae parasitized or injected with CF (0.5 female equivalent) on day 1, levels of JHE activity were depressed during the entire stadium, with a somewhat greater reduction induced by CF injection (~ 3 nmol JH III/min/ml on day 4) than parasitism (~ 8 nmol JH III/min/ml on day 4). Similarly, parasitism and injection of CF both completely prevented the rise in hemolymph ecdysteroid titer observed in control and saline-injected larvae between day 3 and day 7 (rises from ~ 25 to 500-700 pg 20-hydroxyecdysone equivalents/μl hemolymph). We are currently examining the effect of *E. montanus* CF on rates of host JH biosynthesis and prothoracic gland integrity as well as the effect of « Growth Blocking Peptide » (1995; J. Insect Physiol. 41: 1) on the same variables.

05-161

DOWN-REGULATION OF FECUNDITY IN FEMALE *TENEbrio MOLITOR* (COLEOPTERA) IS INDUCED BY HAEMOLYMPH FROM *HYMENOLEPIS DIMINUTA* (CESTODA) INFECTED BEETLES.

M. Major, T. Webb, H. Hurd

Centre for Applied Entomology and Parasitology, Keele University, Staffordshire, U.K.

Fecundity reduction, which occurs in *H. diminuta*-infected *T. molitor*, is associated with changes in the hormonal control of vitellogenesis. Reduction of binding of juvenile hormone to the host follicular epithelium may be due to the presence of a modulatory molecule(s) of either parasite or host origin.

To investigate the hypothesis that such a molecule is present in the haemolymph of *H. diminuta*-infected *T. molitor*, haemolymph from both infected female and male beetles (and controls) was injected into non-infected recipients. To assess any subsequent fecundity reduction, levels of protein in individual ovarian follicles were monitored by ELISA using polyclonal antibodies raised against *T. molitor* vitellin.

Infected beetles harboured parasites at three different developmental stages, 1, 3 to early stage 4 and the mature stage which is infective to rats. Only haemolymph from infected females with parasites at stages 1 and 3 to early stage 4, elicited fecundity reduction in non-infected recipients. Our results thus indicate the presence of fecundity modulatory molecules which are circulating in the haemolymph of *H. diminuta*-infected *T. molitor*.

05-162

GLUTATHIONE S-TRANSFERASES FROM THE FRUITFLY *BACTEROCERA PAPAYAE*

M.F.F. Wajidi & A.M.A. Zambri

Pusat Pendidikan Jarak Jauh, Universiti Sains Malaysia, Pulau Pinang, Malaysia

Glutathione S-transferases (GSTs) belong to a group of enzymes implicated in the detoxification of xenobiotics including chemical insecticides. We are studying the GSTs in *Bacterocera* in order to understand the biochemical mechanisms involved in insecticide resistance.

Cytosol prepared from *B. papayae* larvae showed activity towards 1-chloro-2,4-dinitrobenzene (CDNB), a universal substrate for GSTs. In addition, 1,2-dichloro-6-nitrobenzene (DCNB) activity was also detected in the cytosol. The specific activities of the *Bacterocera* GSTs were comparable to GSTs purified from other insecticide resistant species.

Purification of GSTs were carried out using glutathione sepharose 4B affinity chromatography. The purified enzymes were used to generate polyclonal antibodies which will aid in the study of the expression and regulation of GSTs in this insect.

05-164

LIPID MOBILIZATION IN ADULT *Manduca sexta*: PATHWAY FOR THE SYNTHESIS OF SN-1,2-DG.

E. Arrese, M. Wells

Department of Biochemistry and Center for Insect Science, University of Arizona, Tucson, Arizona 85721, USA.

The pathway for the synthesis of sn-1,2-DG induced by adipokinetic hormone (AKH) was examined. The precursor-product relationship between possible intermediaries was measured after lipid mobilization was induced by AKH. In order to radiolabel the fat body triacylglycerol (TG) pools, late fifth instar larva were fed either [9,10(n)-³H]oleic acid, [9,10-³H]palmitic acid or [1(3)]-³Hglycerol, respectively. This procedure yielded adult insects in which the radioactivity found in the fat body TG represented about 85 % of total radioactivity present in fat body and hemolymph. The positional distribution of radiolabeled fatty acid in the TG showed that 83 % of the label was incorporated in the sn-2-position. Insects fed radiolabeled glycerol showed 80% of the radioactivity in the glycerol backbone and 20 % in the fatty acids. Fat bodies were taken out 1-60 min after AKH injection and total lipid extracts were prepared. The analysis of the radiolabeled lipid components of the fat bodies showed that neither monoacylglycerol nor phosphatidic acid were presents. Conversely, sn-1,2-DG was the only component of the fat body that had a significant increase by the action of AKH. The onset of the DG increase began about 10 min after AKH injection. This result correlated well with the activation of the fat body TG-lipase. The lipase activation began around 5 min after AKH injection and was maximal at 10 min. The release of DG into the hemolymph began about 10 min after AKH injection followed by a gradual increase of the lipid level and the maximal response was observed 2 h after the injection. These results indicated that the stored TG is the precursor of the sn-1,2-DG. The stereospecific hydrolysis of TG by the TG-lipase originates the DGs which are released from the fat body into the hemolymph. This work was supported by NIH grant GM 51296.

05-163

SIZE, COMPOSITION AND PROPERTIES OF THE LIPOPHORIN SURFACE LIPID DOMAIN.

J.L. Soulages, R. van Antwerpen and M.A. Wells.

Biochemistry Department and Center for Insect Science.

PO Box 210088. University of Arizona, Tucson, AZ 85721, USA.

The transformation of HDLp into IDLp and LDLp is the result of the progressive loading of HDLp with DG and an exchangeable apolipoprotein, apolipoprotein-III (apoLp-III). The increase in apoLp-III content, from 0 to 16 molecules per particle, is accompanied by a gradual increase in the zeta-potential which, at pH 8.6, ranges from +1.02 mV for lipophorins without apoLp-III to -7.76 mV for lipophorins containing 16 molecules of apoLp-III. As judged by the changes in the partition constant for trimethylammonium diphenylhexatriene and oleic acid, an average 2-fold increase in the size of the lipophorin lipid-surface takes place when HDLp is loaded with DG and transformed in LDLp. These data, as well as the results obtained by end-point lipolysis with a triacylglycerol (TG)-lipase, indicated that the accessible DG-content increases four to seven times when HDLp is converted in LDLp. Fluorescence polarization of the cationic and anionic lipid probes, trimethyl ammonium diphenylhexatriene and cis-parinaric acid, embedded in eight different subspecies of lipophorin, containing from 12 to 50% DG, showed a small decrease in the surface lipid order when going from HDLp (25% DG) to LDLp (50% DG). Porcine pancreatic phospholipase A₂ was used as probe of the lipoprotein surface. As the DG-content of the lipoprotein increased, a higher enzyme activity against the lipoprotein-phospholipids was observed, with a maximum activity five-fold higher against LDLp than against HDLp. The changes in charge, PLA₂ and triacylglycerol-lipase activity, lipid order and size of the lipophorin lipid-surface provide a link between the structure and properties of the lipophorin surface and the physiological roles of HDLp and LDLp particles. A TRIACYLGLYCEROL-RICH LIPOPHORIN IN THE YELLOW FEVER MOSQUITO, *Aedes aegypti*

Miranda C. Van Heusden, James E. Pennington and Brian Erickson

Department of Biochemistry and Center for Insect Science, University of Arizona, Tucson, Arizona, USA

Lipophorin, the major lipid transport vehicle in insect hemolymph, was isolated from the yellow fever mosquito *Aedes aegypti*. This lipophorin had all the characteristics of the typical insect lipophorin, with the exception that its major neutral lipid component was triacylglycerol (TG) versus diacylglycerol (DG) in other insect species. Insect lipophorin is known for its ability to function as a reusable shuttle in the transport of lipid in hemolymph. The presence of TG may have implications on the metabolism of lipophorin. We investigated whether *A. aegypti* lipophorin functions as a lipid shuttle or whether its metabolism is more similar to that of vertebrate lipoproteins.

Compared to the DG-rich lipophorin of the sphinx moth *Manduca sexta*, *A. aegypti* lipophorin loaded neutral lipid from fat body much less efficiently. Neither concentration, nor density of lipophorin in adult female mosquitoes was affected by starvation, when compared to sugar feeding. Ingestion of a blood meal, however, resulted in a three-fold increase in lipophorin level and a slight increase in lipophorin density, both at 40 h post feeding. These results indicate that *A. aegypti* responds to a need for increased lipid transport by synthesizing and secreting more lipophorin into the hemolymph, rather than by loading more lipid onto existing lipophorin.

05-166

CHARACTERIZATION OF THE LIPOPHORIN RECEPTOR FROM THE MIDGUT OF *Manduca sexta*.K. C. Gondim and M. A. Wells

Department of Biochemistry and Center for Insect Science, University of Arizona, Tucson, AZ USA.

In insects lipids are transported in the hemolymph by lipophorin. Lipophorin acts as a reusable shuttle for lipids, that is, it transfers lipids to the sites of storage or utilization, but the apoproteins of the particle are not accumulated in these tissues, and the lipoprotein can be reloaded with more lipids and reutilized. In the feeding larvae of *Manduca sexta*, lipophorin receives lipids from the midgut and transports them to the fat body, where they are stored. In order to understand how lipid transport in these insects is regulated, we are characterizing the lipophorin receptor from the larval midgut. Midguts were dissected from feeding fifth instar larvae and a membrane preparation was obtained. A filtration assay was used to measure the binding of purified iodinated lipophorin (^{125}I -lipophorin) to its receptor. Non-specific binding was determined in the presence of an excess of non radioactive lipophorin, and the specific binding by the difference between the total and non-specific binding. A time-course of lipophorin binding to the membranes showed that it is a very rapid process, and that equilibrium was reached within 40 min. In the presence of increasing concentrations of membrane protein, corresponding increases in lipophorin binding were observed. Preliminary results indicated that the binding of lipophorin to the midgut receptor does not depend on the presence of calcium and that it can be inhibited by suramin, in a dose dependent manner. Lipophorin binding decreased with increasing pH values, in the range between 5.5 and 8.5. When the membranes were incubated with increasing concentrations of ^{125}I -lipophorin, a saturation curve was obtained, with a K_d in the range of 40 $\mu\text{g/ml}$. It is possible that lipophorin containing different amounts of lipids have varying affinities for the receptor, and this will now be investigated. Supported by: NIH Grant GM 50008

THE STRUCTURAL APOPROTEINS OF LIPOPHORIN, APOLIPOPHORIN-I AND II, ARE ENCODED BY A SINGLE mRNA: (DNA AND DEDUCED AMINO ACID SEQUENCE)K. A. Sundermeyer and M.A. Wells

Biochemistry Department and Center for Insect Science, University of Arizona, Tucson, USA.

Lipophorin is the major hemolymph lipoprotein in insects. It is a large particle that varies in size from 600 to 1000kD, depending on the amount of lipid it contains. Each lipophorin particle consists of two structural apoproteins: apolipophorin I (apoI), $\text{Mr} \approx 250\text{kD}$, and apolipophorin II (apoII), $\text{Mr} \approx 80\text{kD}$. The amino acid sequence of apoI and apoII will help to elucidate many aspects of the structure, function, and biosynthesis of these apoproteins. ApoI and apoII are transcribed into a single 10.5kb mRNA, translated into a single, large polypeptide ($\text{Mr} \approx 350\text{kD}$), and post-translationally cut into apoI and apoII. In this poster we analyze and discuss the main features of the cDNA and the derived amino acid sequence of apoI and apoII from *Manduca sexta* fat body. We also describe the methods and problems encountered in cloning and sequencing a large cDNA. Supported by NIH grant GM50008

05-168

CHARACTERISTICS AND SYNTHESIS OF APOLP-III IN *SPODOPTERA LITURA*Eung-Seok Kim, Beom-Su Kim, So-Joung Choi, Hak R. Kim

Department of Biology, Korea University, Seoul, Korea

ApoLp-III was separated and then purified from the hemolymph of last instar larvae of *Spodoptera litura*. Characteristics and synthetic place were investigated during development. ApoLp-III has molecular weight of 18.6 kDa and contains 17.3% aspartic acid and 13.9% alanine but tryptophan was not detected. Based on N-terminal sequence, apoLp-III of *S. litura* has 48.6% homology with *Manduca sexta* and 30% homology with *Hypantria cunea* but only 11% with *Locusta migratoria*. Fat body, ovary, and testis were tissue-cultured during development. ApoLp-III was synthesized in fat body with great activity in adult stage and also in ovary during early developmental stage. ApoLp-III was confirmed to be present in testis and ovary throughout whole developmental stage by SDS-PAGE. Especially location of apoLp-III in testis was also investigated.

ANCIENT STRUCTURES IN MODERN BRAINS: INSECT PHYLOGENY FROM THE NERVOUS SYSTEM.

N. J. Strausfeld
Arizona Research Laboratories Division of Neurobiology
University of Arizona, Tucson, AZ 85721

Attempts to trace the evolutionary history of animals have traditionally relied on features that are sustained through geological time, such as an exoskeleton that is at least in part preserved in the fossil record and can be used for comparative morphology. More recently, comparison of conserved DNA and RNA have providing insights into relatedness at a variety of taxonomic levels. Here I shall report on novel efforts to construct phylogenies from parsimony analysis using criteria derived from central neural characters.

Results from phylogenetic analysis based on over 60 independent neural characters amongst 23 major arthropod taxa is convergent with results by others obtained from molecular studies. Cladistic analysis demonstrates the ancient origin of certain neural structures, such as the mushroom bodies, which are found throughout the arthropods and annelids. The same technique at a finer level of resolution now suggests that, amongst the Insecta, the Holometabola are polyphyletic and that their constituent taxa have been shoe-horned into this assemblage. Evidence from conserved structures in the phylogenetically ancient olfactory centers and mushroom bodies suggest that the Hymenoptera may be closer to the Orthoptera than to other orders ascribed to the Holometabola. Studies of the central body complex, an insect "invention," supports this view.

IS VENTRAL IN INSECTS DORSAL IN VERTEBRATES?

K. Nübler-Jung and Detlev Arendt¹
Biologisches Institut I (Zoologie), Freiburg, Germany
¹ MPI für Biophys. Chemie, Göttingen, Germany.

The ventral, respectively dorsal nerve cords of insects and vertebrates are generally thought to have evolved independently. Based on molecular and embryological evidence we have recently proposed that the ventral side of insects corresponds to the dorsal side in vertebrates, and that a gastroneuralian ancestor - during its evolution into a chordate - has inverted its dorsoventral body axis. If so, then the ventral, respectively dorsal nerve cords of insects and vertebrates would be homologous structures.

We have now compared the early development of insect and vertebrate brain anlagen. Based on published data we discuss that in the anlagen of insect and vertebrate brains and nerve cords similar genes are being expressed in comparable brain areas with similar functions in the adult. In addition, early axogenesis is also very similar. Insect and vertebrate brains thus appear to develop according to a common ground plan that may have existed already in their common ancestor. - It is proposed that enteropneusts may serve as a unifying conceptual link between gastroneuralian invertebrates and notoneuralian chordates.

The idea that arthropods and vertebrates are built according to a common body plan (with arthropods having chosen to walk around „upside down“) has been proposed some 150 years ago by Geoffroy St.-Hilaire. According to Dohrn (1875), however, vertebrates derive - by dorsoventral inversion - from an annelid-like ancestor with a ventral nerve cord. We show that molecular genetics supports the idea that insects and vertebrates derive from a common gastroneuralian ancestor, and that chordates have inverted their dorsoventral body axis to bear their nerve cord henceforth on their dorsal side.

EMBRYOGENESIS OF THE INSECT BRAIN: FORMATION OF PROLIFERATIVE CLUSTERS, CELL TRANSLOCATION, AND CORTICAL ORGANIZATION

G.S. Boyan and J.L.D. Williams¹. Zoology Institute, University of Munich, Munich, Germany; ¹Max-Planck-Institute, Arbeitsgruppe Kaissling, Seewiesen, Germany

During embryogenesis in the grasshopper, a developmental program transforms a relatively simple, two-dimensional sheet of neuronal precursor cells - called neuroblasts - into the highly complex structure of the mature brain. The transformation begins with the aggregation of the neuroblasts into at least 5 discrete proliferative clusters: pars intercerebralis, protocerebrum, deutocerebrum, tritocerebrum and midline. Aggregation into a cluster is the result of a progressive wrapping of neuroblasts and their progeny by glia cells. These brain-specific proliferative aggregates are established well before axogenesis begins. Since the initial pioneer neurons navigate between the glial-bound proliferative clusters to establish the primary axon scaffold, the clusters may prefigure neuropilar pathways in the brain.

Following establishment of the proliferative clusters, a morphogenesis occurs in which the clusters of proliferating neuroblasts behave as mobile plate-like structures that become repositioned relative to one another in the head. Further, individual identified neuroblasts are displaced independently of other neuroblasts within their proliferative cluster. Translocation may follow routes laid down in the early pre-axogenesis by glia cells. Displacement of putatively equivalent neuroblasts to identical cortical locations in the brain of the grasshopper, the stick insect and the cockroach suggests that the same developmental program operates in various orthopteroid insects.

THE "CENTRAL COMPLEX" IN THE ARTHROPOD BRAIN: IMMUNOREACTIVITY TO PEPTIDE ANTISERA IN SPIDERS AND INSECTS

Hans-Jürgen Agricola¹, Uwe Homberg² and Ernst-August Seyfarth³

¹ Institut für Allgemeine Zoologie und Tierphysiologie, Universität Jena, Erbertstraße 1, D-07743 Jena - ² Institut für Zoologie, Universität Regensburg, D-93040 Regensburg - ³ Zoologisches Institut, Universität Frankfurt, Siesmayerstraße 70, D-60054 Frankfurt

Arthropods are usually considered a monophyletic group, and a central brain structure, the "central body", has been recognized in all arthropod groups (Holmgren, 1916). Based on differences in the position, connectivity, and development of the central body, however, Strausfeld (1993) and Breidbach (1995) suggested that the central bodies of arachnids and insects are not homologous.

We applied immunocytochemical methods to investigate parallels and differences in the neuronal architecture of the central body in insect and spider brains. Our study revealed that antibodies to the neuropeptides allatostatin 1, proctolin, and crustacean cardioactive peptide (CCAP) label neurons of the "central body" in the spider *Cupiennius salei* (Ctenidae) as well as in insects (*Schistocerca gregaria*, *Periplaneta americana*).

In insects the central body together with the protocerebral bridge are subcompartments of the central complex, while a distinct protocerebral bridge has not been recognized in the brain of arachnids. In arachnids and insects, the central body/central complex is a highly ordered neuropil extending across the midline of the brain. In both groups the structure consists of horizontal layers and transverse columns (16 columns in insects, numerous columns in spiders), which in insects form regular fiber chiasmata between the bridge and the central body. In the spider as well as in the locust and cockroach, the central body/central complex is closely connected to the visual system, in part by CCAP-immunoreactive fibers. Allatostatin-immunostaining revealed columnar and tangential elements in both arthropod groups. Detailed morphological analysis suggests interactions of columnar elements from the two brain hemispheres in the central body/central complex.

In summary, peptide immunostaining of the central complex of insects and the central body of spiders reveals remarkable similarities in internal organization and connections to the visual system which do not support the hypothesis that these structures have evolved twice in chelicerates and in insects.

THE CENTRAL COMPLEX IS A HIGHER CENTRE FOR LOCOMOTOR CONTROL IN INSECTS. EVIDENCE FROM NEW *DROSOPHILA MELANOGASTER* MUTANTS (DIPTERA: DROSOPHILIDAE)

R. Strauss

Max-Planck-Institut für biologische Kybernetik, Tübingen, F.R.G.

Cladistics suggest that the central complex of the brain (CC) might be special to insects and to their evolution of locomotion and orientation. The behavioural significance of the CC for walking and certain aspects of orientation was deduced from comparative behavioural studies in *Drosophila* mutant lines with known structural disorders in the CC (Strauss & Heisenberg 1993; J Neurosci 13:1852-61). In the present study we isolated 230 lines out of 10,750 mutagenized flies for their walking impairments in a behavioural screen (Strauss; J Neurogenet, in press). The coordination of legs, joint angles, step lengths, and duration of swing phases were analysed in high resolution using a computerized detector system (Strauss 1993; J Neurogenet 8:250). Their external body and gross brain morphology were inspected.

In 30 lines walking impairments were correlated with structural defects in the CC detectable with light microscopy. Considering the neuronal and non-neuronal extent of the walking system this unexpectedly large fraction of 13% of all lines emphasizes its importance as a higher centre for locomotor control. Two exemplary new lines shall be considered here.

In mutant flies of the line *C141*, affected in an apparently thus far unknown gene, the protocerebral bridge of the CC is disrupted medially. Severe walking impairments, even when studied in high resolution, perfectly parallel those of *no-bridge*^{KS49} flies. The latter mutation in an independent gene causes a median gap in the protocerebral bridge as well (Strauss et al. 1992; J Neurogenet 8: 125-55). This finding strengthens the notion that the protocerebral bridge is involved in the adjustment of step lengths both to achieve turning and secondly to optimize walking speed during straight walking.

Flies of our line *C31* are impaired in the CC and by the same mutation in the thoracal ganglion. When the defective gene is expressed unilaterally throughout the fly, the mosaic individuals continuously turn to the mutated side even when approaching a landmark. The tendency to turn is not observed in unilaterally thorax-defective mosaics with intact brains nor in completely defective *C31* flies. The finding suggests that an intact CC is capable of compensating for the different performances of a defective and a normal body side. A *C31*-impaired brain, however, can no longer balance existing differences.

06-007

EVOLUTION OF THE MOTH EAR: COMPARATIVE PHYLOGENY AND ONTOGENY

J.H. Fullard, J.E. Yack¹ and F.P. Lewis²

Department of Zoology, Erindale College, University of Toronto, Mississauga, ONT, Canada - ¹ Department of Biology, Carleton University, Ottawa, ONT, Canada - ² Department of Biology, McGill University, Montréal, QUE, Canada.

The moth ear represents a valuable opportunity to study the evolutionary pathways of an insect sensory system, both at the peripheral and at the central nervous system level. Moth ears have arisen polyphyletically from pre-adapted proprioceptors located at wing bases. The existence of earless taxa allows for the identification of the ancestral condition of the auditory chordotonal organ, a three-celled stretch receptor complex. This plesiomorphic condition has lost one cell to become the auditory organ in the Noctuidae and two cells in the Notodontidae. Why cellular loss has occurred in these taxa but not in the four-celled ears of the Geometroidea is discussed.

The larvae of Lepidoptera do not possess tympanal ears but have a chordotonal precursor located in the anatomically homologous location as the adult ear. Experiments that ablate the proprioceptor organ in last instar larvae result in adult ears with disrupted tympanal membranes lacking the auditory organ. These results suggest that metamorphosis, with its massive tissue reorganisation may have been the stage in which random mutations leading to the evolution of an ear took place.

06-006

EVOLUTIONARY CONSERVATION OF A PREDATOR EVASION SYSTEM.

J.S. Edwards

Department of Zoology, University of Washington
Seattle WA 98195

Predation has been a fact of life since pre-Cambrian times. The interplay of prey detection and predator evasion has accordingly been a major factor in the evolution of animal form and function. Among the several early-warning sensory systems that serve to alert potential prey, mechanoreceptor input appears to be the most ancient. It served the first terrestrial animals, the arthropods, and is retained to this day by many of them, including hexapods.

Another widespread component of predator evasion systems is the giant interneuron. Sets of interneurons with relatively large axonal diameters occur in many arthropods. Within the Hexapoda a set of abdominal giant interneurons that serve to convey mechanosensory input from abdominal cerci and adjacent mechanoreceptors to thoracic ganglia and the brain in the Archaeognatha, Thysanura and orthopteroid orders appear to be homologous. This apparently conserved system did not persist in recognisable form into the Holometabola, where visually driven descending giant interneurons are widespread.

06-008

CELL LINEAGE AND CELL FATE SPECIFICATION IN THE EMBRYONIC CENTRAL NERVOUS SYSTEM OF *DROSOPHILA*

T. Bossing, K. L  er, H. Schmidt, G. Udolph, J. Urban, G.M. Technau
Institut f  r Genetik, Universit  t Mainz, Saarstra  e 21, D-55122 Mainz, Germany

In the *Drosophila* embryo the CNS develops from a population of neural stem cells (neuroblasts, NBs) and midline progenitor cells which delaminate from the ectoderm according to a stereotyped spatial and temporal pattern. By labelling individual early gastrula cells with DiI we have clarified the entire embryonic lineages of the mesectodermal midline progenitors and of most of the thoracic and abdominal NBs. Some of the NBs give rise to segment specific lineages. The identified wildtype CNS lineages provide a foundation for the analysis of mutants, gene expression patterns and experimental manipulations.

Positional information plays an important role in the specification of the various neural progenitors. Heterotopic single cell transplantations reveal differential commitment of progenitors along the dorsoventral axis of the early gastrula neuroectoderm. These experiments and mutant analysis suggest that signals exist at ventral sites conferring ventral specificities to the cells, and that the ventral midline is involved in their correct positioning. This resembles the situation in vertebrates in which the identity of ventral cells and the position that they occupy in the neural tube appears to depend on signals from the ventral midline (floor plate). Ongoing experiments are aimed at elucidating the putative role of the *Drosophila* ventral midline in specifying cell fates in the adjacent neural and mesodermal tissues.

06-010

TRANSCRIPTION FACTORS IN THE DEVELOPING INSECT NERVOUS SYSTEM-APPROACHES TO THEIR FUNCTION AND THEIR USEFULNESS AS MARKERS

E.E. Ball, D.C. Hayward
Molecular Evolution and Systematics Group, Research School of Biological Sciences, Australian National University, Canberra, Australia

The best characterised insect transcription factors are those involved in controlling segmentation and in determining segmental identity in embryonic *Drosophila*. These same proteins occur in predictable, and frequently serially homologous, subsets of neurons, later in development. A few functional studies have now been carried out using genetic techniques (*Drosophila*), or the injection of anti-sense oligonucleotides (grasshopper), to knock out specific transcription factors, but such studies are just beginning. Genes coding for homologs of the most studied *Drosophila* transcription factors have now been cloned from several other insects, most notably *Tribolium*, *Schistocerca*, *Locusta*, *Precis*, *Manduca*, and *Bombyx*. This allows interspecific comparison of individual transcription factors and a search for patterns of distribution that might suggest a function. For example, the co-occurrence of specific transcription factors in motoneurons and the muscles which they innervate raises the possibility that the factor is controlling expression of a common surface recognition molecule in the axon and its target. Clues to function may also come from changes in the pattern of transcription factor expression during development. Transcription factors are valuable to the insect developmental neurobiologist as cell specific markers, especially when used in conjunction with other markers, and to those interested in neural evolution, as indicators of possible homology. Results presented will be drawn mainly from grasshoppers and *Drosophila* for the transcription factors hunchback, even-skipped, engrailed, Antennapedia, and a probable homolog of deadpan.

06-009

EMBRYONIC DEVELOPMENT OF THE *DROSOPHILA* BRAIN

F. Hirth¹, S. Leuzinger¹, S. Therianos¹, T. Loop¹, W.J. Gehring², K. Furukubu-Tokunaga¹, H. Reichert¹
Departments of Integrative Biology¹ and Biocenter², University of Basel, Basel, Switzerland

We have characterized embryonic brain development in *Drosophila melanogaster* at the cellular and molecular level using antibody probes, enhancer detector strains, and mutant analysis. During embryogenesis, two bilaterally symmetrical cephalic neurogenic regions form. The brain commissure which interconnects these two brain hemispheres is pioneered by axons which project towards the midline in close association with an interhemispheric cellular bridge. The descending longitudinal pathways which connect the brain to the ventral nerve cord are also prefigured by a cellular bridge; pioneering descending and ascending neurons grow along these structures.

We have also studied the roles of the homeobox genes *orthodenticle (otd)* and *empty spiracles (ems)* in embryonic brain development of *Drosophila*. The embryonic brain is composed of three segmental neuromeres. The *otd* gene is expressed predominantly in the anterior neuromere. Expression of *ems* is restricted to the two posterior neuromeres. Mutation of *otd* eliminates the first (protocerebral) brain neuromere. Mutation of *ems* eliminates the second (deutocerebral) and third (tritocerebral) neuromeres. *otd* is also necessary for development of the dorsal protocerebrum of the adult brain. Thus, these homeobox genes are required for the development of specific brain segments in *Drosophila*. The regionalized expression of their homologs in vertebrate brains suggests an evolutionarily conserved program for brain development.

06-011

CELL MIGRATION IN THE EMBRYONIC NERVOUS SYSTEM.
P. F. Copenhaver, A.M. Horgan, M. Snyder, S. Combes, J. Wright
Dept. Cell & Developmental Biology L215, Oregon Health Sciences University, Portland, OR 97201 U.S.A.

During embryogenesis, many cells in the developing nervous system undergo substantial rearrangements by the process of active migration along pre-defined pathways. In insects, cell migration is particularly important during the formation of the enteric nervous system (ENS) that innervates the gut. In the tobacco hornworm, *Manduca sexta*, we have shown that an identified population of undifferentiated neurons (named the EP cells) must migrate along specific muscle band pathways on the gut surface during normal development. Manipulations that inhibit migration cause severe disruptions of the ENS and prevent the gut from being innervated properly. To understand the mechanisms that control this process, we are investigating the nature of specific pathway molecules that guide neuronal migration, and the signal transduction systems by which the EP cells recognize and respond to these cues. One pathway molecule that appears to be required for migration is fasciclin II (MFas II), a cell adhesion receptor that is expressed by both the neurons and the muscle bands during migration. Experiments in embryo culture suggest that MFas II may promote migration via homophilic interactions between receptors on the neurons and muscle cells. We also have found that the onset of migration requires the activation of tyrosine kinases in the EP cells, which may be directly linked to MFas II receptors in the ENS. Other molecules (as yet unidentified) that are associated with non-pathway regions on the gut surface appear to inhibit migration. A second intracellular signaling protein, the heterotrimeric G protein Go  , is also expressed in the EP cells. However, stimulation of Go   causes an inhibition of migration in a calcium-dependent manner, suggesting that Go   may be part of the inhibitory response to non-pathway cues on the gut surface. The activity of these signaling molecules must ultimately regulate cytoskeletal assembly to affect migratory behavior. Using inhibitors of the cytoskeleton, we have shown that both migration and axon outgrowth by the EP cells require actin assembly, but migration is independent of tubulin assembly. We are now exploring how multiple signaling events may be integrated within a developing neuron to regulate its behavior and differentiation. Supported by NIH NS35369.

06-012

ASSOCIATION OF THE NITRIC OXIDE/CYCLIC GMP SYSTEM WITH SYNAPSE FORMATION IN INSECT NEURONS

James W. Truman^{1,2}, Sarah Gibbs¹, and Eldon E. Ball²¹Department of Zoology, University of Washington, Seattle WA, USA - ²Research School of Biological Sciences, Australian National University, Canberra, ACT Australia

Immunocytochemical studies on embryos of *Locusta migratoria* show that many developing neurons go through a phase during which exposure to nitric oxide (NO) can stimulate production of cyclic GMP. This NO responsiveness is typically transient. It always begins after the neuron's axonal growth cone has arrived at its target and usually wanes after synaptic sites have been established. A wide variety of motoneurons, interneurons and sensory neurons show this property. Similar phenomena are evident in other insects such as the silverfish, *Ctenolepisma longicaudata*, the moth, *Manduca sexta*, and *Drosophila melanogaster*. In holometabolous insects like *Manduca* and *Drosophila* neurons show a second period of NO responsiveness at metamorphosis. This is seen both in larval neurons that are establishing new metamorphic contacts and in imaginal neurons that are making connections for the first time. Experiments in *Drosophila* using inhibitors of NO synthase result in neurons that fail to make their proper synaptic connections. We suggest that NO and cGMP constitute part of a retrograde signalling pathway that conveys signals to a neuron from its target thereby allowing the neuron to terminate axon elongation and initiate the processes of maturation and synaptogenesis.

06-014

SPECIES- AND STRAIN-SPECIFIC ANTENNAL LOBE EVENTS MEDIATING SEX ATTRACTION BY PHEROMONES IN MOTHS

B. S. Hansson, S. Anton, W.-Q. Wu, C. Löfstedt

Department of Ecology, Lund University, Lund, Sweden

Mating in moths normally relies on long distance attraction of males by female-produced sex pheromones. The individual pheromone components are detected by different physiological types of receptor neurons on the male antenna. In many moths, however, the sex pheromone mediated behaviour has been shown to depend heavily on the precise ratio between the components of the pheromone blend. No interactions between pheromone components have been observed at the level of the peripheral receptors. Such interactions have been shown by intracellular recordings from antennal lobe interneurons of several moth species.

We have studied three species of moths with respect to blend recognition by antennal lobe interneurons. In two of the species, *Agrotis segetum* and *Ostrinia nubilalis*, the existence of populations with distinct differences in pheromone blends offers an excellent opportunity for comparative studies of the physiological basis of differences in behavioural response to pheromones. In *Trichoplusia ni*, we investigated the physiological correlates of a well established case of redundancy in the multi-component pheromone blend. In the turnip moth, *A. segetum*, antennal lobe interneurons responding specifically to the different blends of the two geographically distinct populations studied were found. The blend of females of the same population as the male under investigation often elicited a stronger neural response. In the European corn borer, *O. nubilalis*, the two pheromone strains that produce reversed ratios of the pheromone components (Z)- and (E)-11-tetradecenyl acetate, were shown to possess proportionally more antennal lobe neurons activated by the major component of the pheromone. Thus recordings from males of the so called Z-strain revealed more Z responding neurons, while recordings from males of the E-strain showed more E responding neurons. When antennal lobe neurons of the male cabbage looper moth, *T. ni*, were contacted intracellularly, blend-specific neurons were encountered. The significance of these neurons for the redundancy phenomenon in the pheromone communication was, however, ambiguous. In conclusion, we provide further support that male moths possess antennal lobe interneurons capable of recognizing pheromone blends and even discriminate between blends containing different ratios of the individual pheromone components detected by the peripheral receptors

06-013

LOW-LEVEL VISION IN HONEYBEES: SIMPLE STRATEGIES FOR FLIGHT CONTROL AND NAVIGATION

M.V. Srinivasan, S.W. Zhang, M. Lehrer¹ and T.S. Collett²Centre for Visual Science, Research School of Biological Sciences, Australian National University, P.O. Box 475, Canberra, A.C.T. 2601, Australia - ¹ Abteilung Neurobiologie, Zoologisches Institut der Universität Zürich, Winterthurerstrasse-190, CH-8057 Zürich, Switzerland - ² Sussex Centre for Neuroscience, School of Biological Sciences, University of Sussex, Brighton BN1 9QG, UK

Recent research has uncovered a number of different ways in which bees use low-level vision for navigational purposes. The distance flown to a food source is gauged by integrating the apparent motion of the visual world that is experienced en route. In other words, bees possess a visually driven "odometer" that is robust to variations in wind load and energy expenditure. Bees flying through a tunnel maintain equidistance to the flanking walls by balancing the apparent speeds of the images of the walls. This strategy enables them to negotiate narrow passages or to fly between obstacles. The speed of flight in a tunnel is controlled by holding constant the average image velocity as seen by the two eyes. This avoids potential collisions by ensuring that the bee slows down when flying through narrow passages. Bees landing on a horizontal surface hold constant the image velocity of the surface as they approach it. This automatically ensures that flight speed decreases with altitude, and is close to zero at touchdown. The movement-sensitive mechanisms underlying these various behaviours seem to be different, qualitatively as well as quantitatively, from those mediating the well-investigated optomotor response.

06-015

CENTRAL NEUROSECRETION AND NEUROMODULATION IN THE MOTH *MANDUCA SEXTA* (LEPIDOPTERA: SPHINGIDAE)

J.G. Hildebrand, N.T. Davis, U. Homberg, P. Kloppenburg, A.R. Mercer, X.-J. Sun

ARL Division of Neurobiology, University of Arizona, Tucson, AZ 85721, USA

As in other insects, the central nervous system (CNS) of *Manduca sexta* exhibits a variety of identifiable neurons that contain, and presumably secrete, neuropeptides and monoamines. Putative neuropeptides may be localized in neurons that project to neurohaemal release sites, in paracrine neurons that apparently subserve focal neurosecretion in the CNS, or in interneurons, colocalized with conventional neurotransmitters and possibly serving as modulatory cotransmitters. Monoamines such as dopamine, octopamine, and 5-hydroxytryptamine (5HT) are found in neuroendocrine cells, peripherally-projecting modulatory neurons, and local and widefield interneurons. It is likely that many of these types of neurons exert local or global neurosecretory influences through various mechanisms of neuromodulation and hence are important for the orchestration of behavior. As a case-in-point, this presentation will focus on a pair of identified, widefield, 5HT-containing interneurons in the deutocerebrum. Morphological investigations of these neurons suggest that they provide centrifugal feedback to the antennal lobes. Neurophysiological studies of the effects of 5HT on antennal-lobe neurons *in situ* and *in vitro* indicate that this monoamine exerts modulatory, and mainly or exclusively "up-regulatory," effects, such as broadening of action potentials and increased excitability of AL interneurons. The possibility that these 5HT-containing neurons might mediate state-dependent changes in olfactory function, and hence in odor-dependent behavior, will be discussed.

A UNIQUE MEMBER OF THE PHEROMONE-BINDING PROTEIN SUPERFAMILY COMMONLY FOUND IN THE TASTE AND OLFACTORY SYSTEMS OF THE FLY AND ITS POSSIBLE FUNCTION.

M. Ozaki, K. Morisaki, W. Idei, K. Ozaki and F. Tokunaga¹

Department of Biology, Faculty of Science, Osaka University, Toyonaka, Osaka, Japan-1
Department of Space and Earth Science, Faculty of Science, Osaka University. Toyonaka, Osaka, Japan

An acidic 14 kDa protein purified in the blow-fly, *Phormia regina* belonged to the insect pheromone-binding protein superfamily, but unlikely other members of the superfamily, it was distributed in both taste and olfactory organs. A similar protein was also isolated in *Drosophila melanogaster*. Considering their distribution, cDNA sequences and structural features, we concluded that the proteins belongs to a unique subfamily whose members have convergently evolved for a common function required for both senses of taste and olfaction. By an electrophysiological experiment using antiserum, we also suggested that these proteins carry fragrant components of natural foods in taste system as well as in olfactory systems.

PRINCIPLES OF ACOUSTIC COMMUNICATION IN TETTIGONIDS

K. Kalmring

Arbeitsgruppe Neurobiologie, Fachbereich Biologie-Zoologie der Philipps-Universität Marburg, D-35032 Marburg, Germany

Tettigoniids perform a pronounced species-specific acousto-vibratory communication which is used in female attraction, in intraspecific male competition but also in spatial distribution of the individuals of a population.

The complex tibial organs of all six legs and the combined auditory-vibratory sensory system of the CNS establish the receiver of this communicatory system, which detects and processes the sound signals emitted by conspecific males.

Recent studies on the receptor organs of different species have revealed that during the evolution of the various species of tettigoniids the sound conducting system of the auditory organs was more readily adapted than the receptors themselves to detect the frequencies in the conspecific song.

TRANSMITTER PLASTICITY IN INDIVIDUAL PEPTIDERGIC NEURONS AND ITS REGULATION BY STEROID HORMONES.

N.J. Tublitz, P.K. Loi, J. Wiley, and H. McGraw

Institute of Neuroscience, University of Oregon, Eugene OR USA 97403

The tobacco hawkmoth *Manduca sexta* contains 4 lateral neurosecretory neurons (LNCs) that undergo a change in morphology and biochemistry during metamorphosis. Several different assays, including single cell bioassays, have determined that the LNCs in larvae express high levels of Cardioacceleratory Peptides (CAPs) and low levels of bursicon. In contrast bursicon expression increases significantly in adult LNCs while CAP levels are below detection. Several lines of evidence suggest that this transmitter switch is under the regulation of the insect ecdysteroid 20-hydroxyecdysone (20-HE). Results from *in vivo* endocrine manipulations indicate that the two 20-HE pulses during the last larval instar affect different aspects of this switch, with the commitment pulse (CP) causing a decline in CAP levels and the subsequent prepupal peak (PP) triggering an increase in bursicon levels. To evaluate the morphological changes seen *in vivo*, individual LNCs from feeding Vth instar larvae were placed in an *in vitro* culture system and exposed to different hormonal regimens for up to two weeks. The morphology of the cultured LNCs was concentration dependent; primary neurite outgrowth was stimulated at CP levels of 20-HE while secondary and tertiary branching was promoted in a concentration of 20-HE that mimics the PP. In this talk I will discuss the experiments leading to these results and the behavioral implications of this plasticity.

FUNCTIONAL CHARACTERIZATION OF CLONED *DROSOPHILA MELANOGASTER* NEUROTRANSMITTER RECEPTORS BY EXPRESSION IN STABLE *DROSOPHILA* CELL LINES.

N.S. Millar¹ and D.B. Sattelle² Wellcome Laboratory of Molecular Pharmacology, University College London, UK¹ The Babraham Institute Laboratory of Molecular Signalling, Cambridge, UK²

Application of molecular cloning and genetics to the investigation of chemical neurotransmission in *Drosophila melanogaster* has resulted in the identification of many putative neurotransmitter receptor encoding genes. Multiple subunits of *Drosophila* ionotropic receptors for GABA, acetylcholine (nicotinic) and L-glutamate, have been identified. G-protein coupled receptors for acetylcholine (muscarinic), 5-HT, octopamine/tyramine and dopamine, have been cloned, and subtypes of several of these *Drosophila* metabotropic receptors have also been identified. The demonstration of functional expression using such methods as electrophysiology, calcium imaging and enzyme assays is an essential step in ascribing roles for cloned, putative neurotransmitter receptors. Expression systems used for *Drosophila* receptors include transient and stable expression in mammalian cells lines, transient expression in *Xenopus* oocytes, transient and constitutive expression in the baculovirus/Sf9 cell expression system. To overcome some of the limitations of expression vehicles used to date, we have generated *Drosophila* S2/M3 cell lines, stably expressing cloned *Drosophila* neurotransmitter receptors, using the plasmid pRmHa3 (containing the metallothionein promoter of *Drosophila*), and a selection plasmid pCoHygro (containing a bacterial hygromycin B phosphotransferase gene). In this way, cell lines have been generated expressing the wild-type and dieldrin-resistant forms of a *Drosophila* ionotropic GABA receptor subunit (RDL) that forms robust homo-oligomers¹ and muscarinic acetylcholine receptors². Thus, the procedure is effective for ionotropic and G-protein coupled *Drosophila* receptors, and lines expressing several other cloned *Drosophila* neurotransmitter receptors are now being characterized. Cell lines facilitate detailed characterization of *Drosophila* receptor subtypes which is often difficult in native membranes containing mixed receptor populations. They permit studies of the interactions of selected neurotransmitter receptors and the intracellular signalling pathways they activate. They also offer improved understanding of both established and novel molecular targets for insect control agents, and may be useful in the generation of high-throughput screening assays.

MOLECULAR BIOLOGY AND EXPRESSION OF NOVEL INSECT GABA RECEPTOR SUBUNITS

R. H. ffrench-Constant, Departments of Neuroscience and Entomology University of Wisconsin-Madison, Madison, Wisconsin 53706

Using the unique approach of isolating drug (PTX) and pesticide (cyclodiene insecticide) resistant *Drosophila* mutants we have cloned a novel GABA receptor subunit gene *Resistance to dieldrin* or *Rdl*. *Rdl* is very different from vertebrate GABA_A receptors because it 1) forms homomultimeric GABA gated chloride ion channels in heterologous systems with high efficiency, 2) shows more extensive alternative splicing, 3) has a different genomic organization and 4) possesses higher sequence identity to glycine receptors than GABA_A receptor subunits themselves (although it does not respond to glycine as an agonist). We have previously shown that resistance is associated with a single alanine> serine replacement within M2 the region proposed to line the chloride ion channel pore (*Nature*, 363, 449, *PNAS*, 90, 1957) and that the mechanism of resistance is brought about by a unique combination of direct changes in the binding site and allosteric destabilization of the drug preferred desensitized state (*J. Physiol.* 479.1, 65). Here we present *in situ* hybridization data on the spatial and temporal expression of *Rdl* (*Invertebrate Neuroscience*, 1, in press) with that of a second *Drosophila* GABA receptor subunit that appears to be a homolog of vertebrate GABA_A receptor β subunits.

NEUROPEPTIDE BIOSYNTHESIS: MOLECULAR MECHANISMS AND NEW INSECTICIDE TARGETS

Richard C Rayne, Michael O'Shea

Sussex Centre for Neuroscience, School of Biology, University of Sussex, Brighton BN1 9QG, UK; ¹ Department of Biology, Birkbeck College, University of London, WC1E 7HX, UK

We are using the corpora cardiaca (CC) of the locust *Schistocerca gregaria* as a model system to study the molecular mechanisms of insect neuropeptide biosynthesis. The glandular CC are particularly homogeneous, containing approximately 6-10,000 intrinsic neurosecretory cells which are devoted to the biosynthesis of the two adipokinetic hormones (AKH I and II) and a set of three dimeric neuropeptides called AKH Precursor Related Peptides 1, 2 and 3 (or APRP 1, 2, 3). These five products are generated by the post-translational processing of two related monomeric prohormones. We have determined the temporal order and the intracellular location of these processing events, as well as the biochemical mechanisms by which the processing reactions are accomplished. In addition, we have reconstituted *in vitro* the steps in proteolytic processing of the dimeric AKH I precursor.

Using NMR spectroscopy we have determined the solution structure of the AKH I precursor in hopes of identifying the structural features of the precursors which govern processing endopeptidase specificity. By modifying the structure of the precursor in the vicinity of the processing site we are able to either prevent processing or not. Such experiments suggest that an Ω -loop structure is important in molecular recognition by the endopeptidase. Our work may provide the basis for the design of specific enzyme inhibitors to be used as lead compounds for new insecticides.

Supported by BBSRC grant GR/J33234.

SHAKING-B IS REQUIRED FOR THE ESTABLISHMENT OF ELECTRICAL SYNAPSES IN THE *DROSOPHILA* GIANT FIBRE SYSTEM.

P. Phelan, M. Wilkin, M. Todman, L. Stebbings, J. P. Bacon, J. A. Davies
Sussex Centre for Neuroscience, University of Sussex, Brighton BN1 9QG

The establishment of the highly specific synaptic connections between neurons must require the expression of particular genes. One candidate is the *Drosophila shaking-B* locus. *shaking-B* was discovered by screening for mutations that abolish the fly's escape response, a behaviour mediated by a network of identifiable neurons known as the giant fibre system (GFS) (Thomas & Wyman, 1984. *J. Neurosci* 4: 530-538).

Genetic analysis has revealed that at least 2 distinct functions reside at the *shak-B* locus, one being required for viability and the other for the establishment of some GFS electrical synapses. We have cloned *shaking-B* and have isolated cDNAs reflecting multiply spliced transcripts. The characterisation of different mutations has enabled us to distinguish between transcripts required for essential and neural *shak-B* functions (Crompton et al., 1995. *Dev. Biol.* 170: 142-158).

We are examining the role of *shak-B* in synapse formation. Using an enhancer trap line, we followed the development of the giant fibre, the major descending neuron of the GFS pathway and injected Lucifer Yellow intracellularly to describe and to map the development of the electrical synapses it forms. Immunocytochemistry with *Shak-B* peptide antisera demonstrates that the protein is first localised to the region of the GF synapses at about the time of synaptogenesis (Phelan et al., *J. Neurosci.* in press). We see no corresponding expression in neural *shak-B* mutants in which we show that all of the electrical synapses in the GFS are dye uncoupled.

shak-B function is clearly required for the establishment of electrical connections. The protein may itself be a structural component of synaptic gap junctions or play a role in the assembly and/or stabilisation of the junctional complex.

NEUROPEPTIDE BIOSYNTHESIS: MOLECULAR GENETIC ANALYSIS IN *DROSOPHILA*.

R Benveniste, N Jiang, MS Roberts, RC Johnson*, A Kolhekar*, BA Eipper*, RE Mains*, PH Taghert, Dept. of Anatomy & Neurobiology, Washington University School of Medicine, Saint Louis, MO, USA, and *Dept. of Neurosci. & Physiology, Johns Hopkins Med. School, Baltimore MD, USA.

We are studying neuropeptide biosynthesis in *Drosophila* to employ genetics in defining mechanisms that regulate the appearance and use of neuropeptides. We have defined two questions relating to this problem.

The first considers the transcriptional mechanisms that restrict neuropeptide gene expression to a small subset of CNS neurons. The *FMRamide* neuropeptide gene is expressed in ~50 diverse neurons. Using transgenic animals, we have demonstrated both positive and negative transcriptional regulation of this gene. Further, our results indicate the existence of cell-specific enhancer elements within the *FMRamide* promoter, that are small and that may bind specific sets of transcriptional regulators. To date, we have found two such enhancers (size: 170 and 190 bp, respectively); they regulate reporter expression in 2 of the ~15 different cell types that normally express the *FMRamide* gene.

The second question considers the processing of neuropeptide precursors by enzymes. 50% of all neuropeptides are amidated at their C termini: this event is the final step in neuropeptide biosynthesis. Although *Drosophila* contains both enzymatic activities necessary to achieve amidation, to date we have only found gene sequences for the first step, hydroxylation of C terminal glycine residues. This single copy gene is expressed in a wide variety of tissues; in the CNS, it is highly expressed in identified neuropeptide neurons, and weakly expressed throughout the tissue. We are currently searching for mutations in this gene with which to evaluate its *in vivo* contribution to neuropeptide biosynthesis.

06-024

FUNCTION OF INSECT EPITRACHEAL ENDOCRINE SYSTEM

D. Zitnan and M.E. Adams

Institute of Zoology, Slovak Academy of Sciences, Bratislava, Slovakia
Department of Entomology, University of California, Riverside, CA, USA

A novel, segmentally distributed endocrine system of epitracheal glands (EG) in moths and other insects is implicated in the control of ecdysis. In moths, individual glands are attached to the trachei near each spiracle and are composed of a large peptidergic Inka cell and 2-3 smaller glandular cells. Before initiation of ecdysis, Inka cells are white and show strong immunoreactivity with antibodies to small cardioactive peptide B and FMRFamide. Upon initiation of ecdysis, Inka cells decrease in size and lose their white colour and immunoreactivity. Injection of EG extracts into pharate larvae, pupae and adults up to 1-7 days prior to natural ecdysis triggers pre-ecdysis followed by ecdysis behaviour within 2-10 min. Exposure of the isolated central nervous system (CNS) to EG extract triggers motor bursting patterns similar in frequency and duration to pre-ecdysis and ecdysis behaviours observed *in vivo*. We isolated novel "ecdysis triggering hormones" (ETH) from *Bombyx mori* and *Manduca sexta* EG with potent ecdysis activity *in vivo* and *in vitro*. ETH is produced solely by Inka cells as indicated by immunohistochemical staining with antiserum specific against ETH N-terminal. Inka cells also produce a set of nonrelated peptides with ETH-like activity and FMRFamide-like peptides (FLP), which are expressed by different genes during intermolt period and released at the end of each instar. Expression of these genes and development of the CNS sensitivity to ETH seems to be regulated by ecdysteroids, while release of the ETH and FLP from Inka cells is likely regulated by eclosion hormone. ETH may directly act on the CNS as an immediate blood borne trigger for ecdysis, while other Inka peptides regulate events associated with this behaviour.

THE *DROSOPHILA* BRAIN: FROM TWO- TO THREE-DIMENSIONS

L.A. Meinertzhagen

Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1

Drosophila melanogaster is the organism of choice for genetic analyses of function and, especially, development of the nervous system. The ready availability of molecular probes in *Drosophila* provides powerful new methods to examine and visualise the brain's anatomy. These are often from the patterns of nuclear localisation of gene products, however, and must be integrated into the anatomy of pathways and identified neurons, which are mostly described from the pattern of neurites rather than the positions of the somata. Most recent studies address the adult brain, but the need for similar approaches in the little-studied larval brain is no less acute. The ease with which the larval brain can be dissected out, and its handy dimensions at this stage of the life-cycle, have promoted the recent widespread use of the larval CNS in wholemount preparations. These are being widely used to screen and view patterns of gene expression in enhancer trap lines, especially GAL4 lines. We have reconstructed the 3-D surfaces of the brain and neuropil regions, from profiles in consecutive semithin sections stained by the osmium-ethyl gallate method, using a Silicon Graphics computer and ICAR 5.0.1 (ISG Technologies Inc., Canada). Images are grabbed from micrographs aligned, *seriatim*, using AMICUS (ISG) to compare each image with others, obtaining the best fit by eye. Virtual sections of the reconstructed brain can then be compared with views of the larval brain derived from confocal image stacks of intact, wholemount brains stained with propidium iodide and other cellular markers. Such comparisons not only validate the accuracy of the reconstructions, but also allow neuropil regions and their fibre tracts to be recognised in orthogonal section planes from their profiles identified in the section plane reconstructed in 3-D. These approaches are preliminary to localising the staining patterns, or expression domains of genes, to the somata of specific cells or cell populations, from material sectioned in a variety of planes by various means (from frozen sections to confocal images). Even though some regions of the larval CNS, especially the developing optic lobes of the imaginal brain, pose a significant challenge to the ability of computer imaging methods to derive reconstructions at single-cell resolution, the latter are nevertheless also a first step to a developmental series of such reconstructions. Such series are essential for time-lapse views both of gene expression and of regional morphogenesis. Supported by grants from NSERC: CPG 0181755 and EQM0153222.

THE INSECT BRAIN: AN EVOLUTIONARY ACCOMPLISHMENT IN MINIATURIZATION AND CONVERGENCE.

N. J. Strausfeld

Arizona Research Laboratories Division of Neurobiology
University of Arizona, Tucson, AZ 85721

That the biomass of insects outweighs all other organisms may be less of a testimony to their evolutionary success than the remarkable sophistication of their central nervous systems. Amongst arthropods, insect brains shows the closest resemblance to those of vertebrates, particularly with respect to the organization of their visual, olfactory, and leg motor neuropils. One phylogenetically ancient higher center, the mushroom bodies, demonstrate an evolutionary jump in the pterygote insects, becoming a double pair rather than singly paired as in apterygotes and other arthropods. In certain of the larger Orthoptera and Hymenoptera, these paired double centers can comprise nearly a million nerve cells. Functions ascribed to them are reminiscent of functions ascribed to mammalian pyriform cortex, hippocampus, and neocortex. Centers that are characteristic of insects, such as the central body complex, suggest comparisons with the cerebellum. At the output level, the organization of descending pathways onto motor centers suggests population coding, a read-out mechanism thought to be typical of vertebrate CNS. In this talk I shall outline a few such examples from insect brains which, as exclaimed by Ramon y Cajal 80 years ago, make those of vertebrates look crude by comparison.

06-027

THE ANTENNAL LOBE OF *DROSOPHILA MELANOGASTER*

Reinhard F. Stocker, Nanaë Gendre and Gertrud Heimbeck

Institut de Zoologie, Université de Fribourg, 1700 Fribourg, Switzerland

The antennal lobe (AL) of *D. melanogaster*, the primary olfactory association center, consists of 30-40 glomeruli. It derives from a non-glomerular larval precursor. Five of the glomeruli in the adult AL are exclusive targets of the ipsilateral antenna, the remaining are bilateral. Individual afferent fibers are glomerulus-specific. Sensory projections appear to be ruled by sensillum type rather than topographically.

Local interneurons (LI) of the AL have lateral cell bodies and establish arborizations in all of the glomeruli. Relay interneurons (RI) connect individual glomeruli with the calyx of the mushroom bodies (MBs) and with the lateral protocerebrum (LPR). Their cell bodies are located either anterodorsal, lateral or ventral to the AL. AL interneurons derive from a single pair of lateral neuroblasts that begins to divide early in larval life, and from others that initiate mitosis later, with a peak of 10-12 pairs of dividing neuroblasts in the late 3rd larval instar.

Application of hydroxyurea (HU) to early 1st instar larvae leads to the loss of the MBs and to a volume reduction of the AL¹. The latter changes are due to HU-induced ablation of the lateral neuroblast¹. To identify the elements affected by this procedure, we applied HU to GAL4 enhancer trap lines expressed in specific types of AL interneurons.

Untreated flies of line *GH146* express GAL4 in RI and in 30-50 fibers extending through the MBs. HU application leads to the loss of RI with lateral cell bodies only. Although obvious MBs are lacking, 30-50 fibers occupy positions reminiscent of the MBs. From the surviving RI, axons extend to the LPR, but do not form side-branches in the presumed calyx region. Line *GH298* expresses GAL4 in LI, elements which become completely ablated by HU.

These data suggest that LI and the RI with lateral cell bodies derive from the early-dividing lateral neuroblast, whereas the remaining interneurons are formed by neuroblasts that undergo mitosis later on in larval life. HU severely affects the MBs, without ablating them completely.

STRUCTURAL AND FUNCTIONAL ANALYSIS OF THE *DROSOPHILA* MUSHROOM BODIES

T. Raabe and M. Heisenberg

Institut für Genetik, Universität Würzburg, Theodor Boveri Institut für Biowissenschaften, Am Hubland, Würzburg, Germany

The two mushroom bodies (MBs) in the *Drosophila* brain consist each of about 2500 Kenyon cells that are derived from 4 neuroblasts proliferating during embryonic and larval stages. MBs show a high degree of structural plasticity. Kenyon cells shed and regrow their fibers during metamorphosis. Fiber number in the peduncle and the volume of the calyx depend on the growth conditions during larval stages and on sensory experiences during adulthood. Our aim is to study the molecular and cellular mechanisms underlying the process of structural plasticity. We use Gal-4 enhancer trap lines that label specific subsets of Kenyon cells allowing us to follow them during development. Several mutations have been isolated that interfere with normal mushroom body development. For three mutations we have started the molecular characterization of the corresponding genes.

MBs are required for normal odor discrimination learning. In the mutant *mushroom body miniature*¹ (*mbm*¹) acquisition but not memory is affected (deBelle and M.H., in prep.) For colour and pattern discrimination learning MBs are dispensable, irrespective of whether the training is classical or operant. However, in flies without MBs, pattern discrimination learning can be abolished by 220ms dark periods during training (R.Wolf and M.H., Neurobiology Conference, Göttingen 1996). This finding suggests that the role of MBs in learning needs to be reconsidered.

06-030

THE SUBOESOPHAGEAL GANGLION AS A NEUROSECRETORY CENTER IN INSECTS

P. Bräunig

Institut f. Zoologie, Technische Universität München, Garching, Germany

The general believe about the suboesophageal ganglion (SOG) of insects is that its only function is the coordination of the mouthparts. More recent work has shown, that apart from this task the SOG also represents a higher order motor center for the coordination of walking, flight, respiration, stridulation, and the generation of neck movements. Even more recent is the notion that the SOG is involved in neuroendocrine control to an extent that was previously unsuspected. Next to the brain, the SOG appears to contain the largest number of neurosecretory cells. Morphologically complex types of neurosecretory cells project into the entire central nervous system, the retrocerebral glandular complex, the lateral heart nerves, or form neurohaemal networks on the surface of peripheral nerves. Additional data even give hints that the SOG is fourth functional complex: neuronal and/or neuroendocrine control of the foregut.

THE CENTRAL COMPLEX: EVIDENCE FOR A ROLE IN POLARIZED-LIGHT ORIENTATION

U. Homberg, M. Müller, H. Vitzthum

Institut für Zoologie, Universität Regensburg, 93040 Regensburg, Germany

The central complex (CC) comprises a group of neuropils in the center of the insect brain. It consists of the protocerebral bridge, the upper and lower division of the central body and the paired noduli, and is closely connected to the lateral accessory lobes (LAL) of the brain (reviewed by Homberg 1987, in AP Gupta [ed] *Arthropod brain*, Wiley, New York, pp 347-367). We have examined the organization and functional role of the central complex in the locust *Schistocerca gregaria*.

The CC communicates with the ventral nerve cord via ascending and descending neurons to and from the LAL. These neurons as well as many CC neurons show activity changes associated with stationary flight, suggesting a role of the CC in certain aspects of flight control (Homberg 1994, *J Comp Physiol A* 175:597-610). Two pathways, the posterior and anterior optic tracts, provide visual input to the CC and LAL. Many and perhaps all neurons associated with the lower division of the central body are sensitive to polarized light delivered to dorsal areas of the compound eyes. The responses of these neurons show polarization opponency, i.e. e-vectors eliciting maximal tonic excitation are oriented 90° to e-vectors causing maximal tonic inhibition. Some inputs to the CC originate in the accessory medulla of the optic lobe, a neuropil which has been implicated with the circadian pacemaking system (Würden and Homberg 1995, *J Comp Neurol* 362:305-319). These inputs might serve for time compensation in polarized-light processing in the CC. Taken together, the data suggest that a subsystem of the CC serves a role in compass orientation of the locust with respect to the sky polarization pattern.

Supported by DFG grants Ho 950/9-1 and 950/4-4.

06-031

EXPRESSION AND FUNCTION OF DROMYOSUPPRESSIN IN THE *DROSOPHILA* BRAIN.R. Nichols, M. Dickerson, J. McCormick, and K. Paisley
Departments of Biological Chemistry and Biology,
University of Michigan, Ann Arbor, MI USA

We have isolated and characterized the dromyosuppressin peptide (TDVDHVFLRFamide, DMS). DMS is an abundant peptide expressed in the brain and gastrointestinal tract at all stages of development. DMS immunoreactive processes project from neurons in the superior protocerebrum to innervate the anterior portion of the dorsal vessel.

We have established an *in vivo* assay and demonstrated that DMS inhibits *Drosophila* heart rate in a dose dependent manner. The amino acid residues critical for cardioinhibitory action have been identified using the method of alanine scan. We are utilizing a pharmacological and genetic approach to determine the mechanism of action of DMS.

The dromyosuppressin gene (*Dms*) has been isolated and cytologically localized to the right arm of the third chromosome at 96A1.

06-032

**NEUROPEPTIDES IN THE INSECT BRAIN: WHAT ARE
THEIR MESSAGES?**

D. R. Nässel

Department of Zoology, Stockholm University, Stockholm, Sweden

A multitude of neuropeptides are known to be synthesized by neurons and neurosecretory cells of the insect brain. At present we have no information about the physiological functions of any one of these peptides within the brain itself, but for some of them hormonal actions have been determined or at least indicated. Two families of myotropic insect neuropeptides have been selected as examples to illustrate the diversity of putative neuropeptide actions: the leucokinins (LKs) and the tachykinins (TKs). In most insect species analyzed to date the LKs are likely to be utilized both as neurohormones and neuromodulators/co-transmitters, whereas the TKs appear to be only neuromodulators/co-transmitters. In the brain of the cockroach *Leucophaea maderae*, both the LKs, and the recently isolated TKs are found in several isoforms. Immunocytochemistry (ICC) has given indications of putative sites of release of the LKs and TKs in *L. maderae*. The LKs (probably all eight isoforms) can be released from corpora cardiaca and may act as diuretic and myoactive hormones. In the brain LKs are present in distinct sets of neurons and may have defined actions as regulators of behaviour. Also in interneurons several, if not all, LK isoforms appear co-localized. The TKs on the other hand are distributed in larger numbers of diverse neuron types and appear more likely to be utilized as co-transmitters with distributed functions. Co-localization of different the TK isoforms has not yet been determined for *L. maderae*, but has been shown for some neurons in *Locusta migratoria*. A brief comparison between *L. maderae*, *L. migratoria* and *Drosophila melanogaster* is made to highlight some preserved and some variable features of the neuronal and neuroendocrine systems utilizing leucokinin- and tachykinin-like peptides.

06-033

PHOTOPERIODIC RECEPTOR IN *RIPTORTUS CLAVATUS*: REGIONAL DIFFERENCE IN THE COMPOUND EYE

A. Morita, H. Numata

Department of Biology, Faculty of Science, Osaka City University, Osaka, Japan

The bean bug, *Riptortus clavatus* (Thunberg) (Heteroptera: Alydidae) shows a long-day photoperiodic response that controls adult diapause. The location of photoreceptors for the photoperiodism was examined in *R. clavatus* by complete or partial removal of photoreceptor organs. Even after one compound eye or both ocelli were removed, the insects were sensitive to photoperiod. After both compound eyes were removed, however, the insects reproduced regardless of the photoperiod. Therefore the photoreceptors for photoperiodism were not in the ocelli but in the compound eyes. To clarify whether the ommatidia in the compound eye have a regional difference in the reception of photoperiod, photoperiodic sensitivity was examined after one compound eye and a part of the contralateral one were removed. Only when the central region of the compound eye was removed, the insects lost the photoperiodic sensitivity. Therefore the ommatidia in the central region of the compound eye play the principal role in the reception of photoperiod.

06-035

ODOUR-GUIDED HOST-FINDING BY HAEMATOPHAGOUS MOSQUITOES: IDENTIFICATION AND NEURAL ENCODING OF HOST ODOURS (DIPTERA; CULICIDAE).

J. Meijerink, J.J.A. van Loon.

Department of Entomology, Wageningen Agricultural University, Wageningen, The Netherlands.

In the process of odour-guided host-finding mosquitoes perceive volatiles by different kinds of sensory receptors, situated on the antennae and palps. Sensitivity and specificity of the olfactory receptors of the mosquito *Anopheles Gambiae* s.s., an important vector of human malaria, were studied by using electrophysiological methods.

Responses of single olfactory neurons were recorded to mixtures of fatty acids known to be attractive in windtunnel bio-assays as well as to individual fatty acids. Sensitive neurons for short chain fatty acids were found in characteristically shaped medium sized sensilla trichodea, a type abundant on the female antenna.

Furthermore, sensory responses were used to assist the identification of potential host attractants by combining a gas chromatograph with electrophysiological set-ups for electroantennogram (EAG) or single cell (SC) recordings.

Scanning electron microscopy studies on the antennae of *An. gambi-ae* were performed to supplement electrophysiological studies with morphological information. Preliminary observations indicate that the sensilla trichodea (known to house olfactory receptors) differ from those of other well-studied *Anopheles* species, like *An. stephensi*.

06-034

PHOTOPERIODIC RECEPTOR IN THE BAND-LEGGED GROUND CRICKET, *PTERONEMOBIUS NIGROFASCIATUS*

S. Shiga, H. Numata

Department of Biology, Faculty of Science, Osaka City University, Osaka, Japan

In *Pteronemobius nigrofasciatus* Walker (Orthoptera: Gryllidae), the induction of egg diapause is controlled by a long-day photoperiodic response in the parental generation and the critical daylength in our strain (Osaka, Japan) is between 13 and 14 hr at 25°C. When crickets were reared under a short-day (LD 12:12) photoperiod and then transferred to a long-day (LD 16:8) photoperiod upon adult emergence, the adults mainly laid nondiapause eggs. However, adults maintained continuously under short-day conditions laid diapause eggs. When compound eyes were bilaterally removed after adult emergence, the crickets mainly laid nondiapause eggs, irrespective of the photoperiod. Thus, the adults completely lost their sensitivity to photoperiod after bilateral removal of their compound eyes. Unilateral removal of the compound eye also affected the crickets under a short-day photoperiod, and the incidence of diapause eggs was intermediate between that laid by intact adults and that laid by adults after the bilateral removal of compound eyes. The incidence of diapause eggs in sham-operated crickets was not significantly different from that in intact crickets under both sets of photoperiodic conditions. These results show that *P. nigrofasciatus* use the compound eyes as a photoperiodic receptor.

OLFACTORY SENSILLA AND RECEPTOR NEURON RESPONSES OF *PHORACANTHA SEMIPUNCTATA* (COL.: CERAMBYCIDAE) TO HOST AND NON-HOST TREE COMPOUNDSO. Lopes¹, E. Barata¹, H. Mustaparta², J. Araujo¹¹ Departamento de Biologia, Universidade de Évora, Évora, Portugal² Department of Zoology, University of Trondheim, Norway

Phoracantha semipunctata is a wood borer longhorned beetle specific of *Eucalyptus*. The odour of *E. globulus* foliage and logs is an important orientation cue in the host finding behaviour of this insect. Olfactory sensilla on the antennal flagellum of *P. semipunctata* could be distinguished with scanning and transmission electron microscope. They were smooth, thin and multiporous - walled pegs. At least two olfactory receptor cells were identified with them, from which branched outer segments reach into the cuticular peg. "Head-space" volatiles evaporated from the foliage of *E. globulus* and from the foliage of the non-hosts *Pinus pinaster* and *Olea europaea* were separated in the gas chromatograph (GC) capillary column. The effluent was split at the end of the column, leading one half of the eluent to the GC-detector and the other half out of the GC-oven to the insect antenna during recording of receptor neurons activity associated with olfactory sensilla. In a sample of 42 receptor neurons, we defined 26 neuron types based on the number of compounds that elicited a response. We did not find neurons that responded to more than 4 different compounds. One neuron type responded specifically to a single not identified compound only present in the non-host *O. europaea*. The results suggest that the insect might have a population of neurons tuned to the reception of compounds only present in non-host species. These specific receptor neurons might enable the insect to a unambiguous detection of non-hosts and ready exhibition of avoidance behavior.

PLANT-ODOUR RESPONSE PROFILES OF APHIDS: ELECTROANTENNOGRAMS OF *MEGOURA VICIAE*, *APHIS FABAE*, *MYZUS PERSICAE* AND *BREVICORYNE BRASSICAE*

J.H. Visser, P.G.M. Piron, J. Hardie¹
Research Institute for Plant Protection IPO-DLO, Wageningen, The Netherlands - ¹ Department of Biology, Imperial College at Silwood Park, Ascot, United Kingdom

In order to identify chemicals, which are involved in host location of aphids, a wide collection of plant odour components was screened on the antennal responses in four aphid species, i.e., the vetch aphid *Megoura viciae* Buckton, the black bean aphid *Aphis fabae* Scop., the peach-potato aphid *Myzus persicae* (Sulz.) and the cabbage aphid *Brevicoryne brassicae* (L.), as recorded by the electroantennogram technique. From the response profiles it is obvious that aphids, in general, show distinct sensitivities for (a) general green leaf volatiles, e.g., (*E*)-2-hexenal, (b) benzaldehydes, 4-methoxybenzaldehyde, (c) carvones, (-)-(*R*)-carvone (d) citronellal, (e) nitriles, hexano- and heptano-nitrile, and (f) isothiocyanates, butyl and 4-pentenyl isothiocyanate. Each of the aphid species differs in varying degrees from the general response profile. It is noteworthy that the response profiles cover potential attractants as well as suspected repellents. Furthermore, we studied (a) the response profiles of different aphid forms in *A. fabae* and *M. persicae*, (b) the response profiles of two clones in *M. persicae*, and (c) the effects of rearing conditions (host plants and artificial diet) for *M. persicae*.

ANTENNAL COCKROACH PROTEIN PHOSPHORYLATION IN THE COURSE OF THE TRANSDUCTION OF THE OLFACTORY MESSAGE

A. Tirard, M. Renucci, L. Sreng, J. Khlat and J.L. Clément
CNRS-UPR 9024, LNB-Communication Chimique, Marseille France
Current evidence implicating second messengers such as inositol triphosphate or cGMP in molecular mechanisms underlying insect olfaction suggests that pheromonal signals act on specific protein phosphorylation. To further validate this hypothesis, we studied the effects of second messengers and pheromonal blend on phosphorylation of antennal proteins in the male cockroach *Periplaneta americana*.

-1- Proteins from adult male antennae were phosphorylated *in vitro* in the presence of [γ ³²P]-ATP, then separated by SDS-PAGE. A wide range phosphopolypeptides were visualized. Addition of Ca⁺⁺/calmodulin to the incubation medium enhanced phosphorylation of polypeptides with molecular weights of 38, 48, 51, 54 and 58 kDa. By stimulating PKC, Ca⁺⁺/Phosphatidyl-Serine (PS)/Phorbol Myristate Acetate (PMA) led to the appearance of three phosphopolypeptides of 36, 70 and 120 kDa. In the presence of cAMP, two polypeptides of 46 and 42 kDa appeared. The 42 kDa polypeptide also appeared in the presence of cGMP. Addition of spermine enhanced phosphorylation of various polypeptides including phosphopolypeptides of 23, 26/27, 28, 32, 38, and 54 kDa.
-2- Comparison of antennal polypeptide content with that in the cerci, leg, brain, and fat body showed that the 28, 36, and 48 kDa polypeptides were specific to antennae.
-3- *In vitro* phosphorylation of proteins obtained from antennae subjected to pheromonal stimulation for 16 seconds prior to homogenisation revealed inhibition of the 120, 70, 64, 38, 28, and 26/27 kDa polypeptides and strong stimulation of the 58, 54, 51, 48, and 32 kDa polypeptides. A 107 kDa polypeptide was observed only after pheromonal stimulation by Ca⁺⁺/PS/PMA.
These findings suggest that Ca⁺⁺ and PKC-dependent protein phosphorylation pathways play an important role in the transduction of pheromonal signals in antennae of male cockroach *P. americana*. They also suggest that polyamine-dependent phospho/dephosphorylations are implicated in the transmission of olfactory messages. We speculate that specific phosphoproteins modulate sensitivity and signal amplification during the olfactory transduction process.

SINGLE CELL RESPONSES IN MALE *Agrotis segetum* SEXUAL PHEROMONE PERIPHERAL RECEPTORS IN A WIND TUNNEL GENERATED PHEROMONE PLUME

Peter G. Valeur, Christer Löfstedt & Bill Hansson
Department of Ecology, University of Lund, Sweden

Single cell responses from male *Agrotis segetum* Schiff. (Lepidoptera: Noctuidae) pheromone receptors were recorded in a wind tunnel 1.5 meters downwind of a pheromone source. We used rubber septa and filter paper with single pheromone components / complete blends with loads varying between 0.001 - 1000 μ g. We also used excised female pheromone glands. Recordings were made during 2 minutes of exposure and the resulting signal was analysed for number of spikes, number of spike trains and mean number of spikes per spike train. We have established dose-response curves for Z5-10:OAc and Z7-12:OAc cells. In this way we were able to directly compare pheromone release rates from syntethic baits and female glands at close to natural levels. We also describe the plume structure from a single cell point of view.

06-040

SINGLE-SENSILLUM RESPONSES OF MALE *RHYACOPHILA NUBILA* (TRICHOPTERA; RHYACOPHILIDAE) TO POSSIBLE SEX PHEROMONE COMPONENTS

L. M. C. Larsson and B. S. Hansson
Department of Ecology, Lund University, Lund, Sweden.

This study for the first time shows responses of single receptor neurons on the antennae of male caddisflies (Trichoptera) to possible female sex pheromone components. As a sister order of the Lepidoptera, the Trichoptera have attracted some interest in the matter of pheromone communication. Pheromone systems similar to those found in primitive Lepidoptera have been demonstrated in Trichoptera, suggesting the possibility of a common origin. Studies of caddisflies and primitive moths could give an insight regarding the origin and evolution of the lepidopteran systems of pheromone communication. The aim of the present study is to gather information about the peripheral level of pheromone detection in Trichoptera, which could serve as a basis for phylogenetic comparisons with the corresponding apparatus in Lepidoptera, and as a stepping stone for further investigations of the neural integration of pheromone signals in Trichoptera.
Six compounds, heptan-2-one, (R)-heptan-2-ol, (S)-heptan-2-ol, nonan-2-one, (R)-nonan-2-ol, and (S)-nonan-2-ol were tested on the antennae of 14 male *Rhyacophila nubila*, with tungsten single-sensillum techniques. These compounds show EAD activity in the males and all except the two (S)-enantiomers are also produced by the females. Of 93 neurons examined, a majority showed a high sensitivity and were selectively tuned to one of the compounds (R)-heptan-2-ol, (S)-heptan-2-ol, or nonan-2-one. No neurons selectively tuned to the compounds heptan-2-one, (R)-nonan-2-one, or (S)-nonan-2-ol were found. The results strongly support the hypothesis that some of the tested compounds are part of the female sex pheromone blend. They also show that the males have the ability to differentiate between chiral isomers at the receptor neuron level. This suggests that the pheromone signal used in *R. nubila* could be very similar to the signal used in the lepidopteran family Eriocraniidae. This fact also provides further support for a relatedness between trichopteran and lepidopteran sex pheromone systems. The males possess receptor neurons sensitive to (S)-heptan-2-ol, a compound which is not produced by the conspecific females. The possible role of these receptor neurons could be to mediate an avoidance of heterospecific females.

CENTRAL NERVOUS PROCESSING OF AGGREGATION
PHEROMONES IN FIFTH INSTAR DESERT LOCUSTSR. Ignell, S. Anton, B.S. Hansson
Dept of Ecology, Lund University, Lund, Sweden

Adult and nymphal *Schistocerca gregaria* aggregate in response to two different releaser pheromone systems. Adult insects aggregate only in response to adult male produced odours, whereas the nymphal volatiles only elicit a behavioural response in the nymphs (Torto *et al.*, Chem Ecol 20:1749-1762, 1994; Obeng-Ofori *et al.*, Entomol Exp Appl 73:85-91, 1994). Like in the cockroach, *Periplaneta americana*, the desert locust show a drastic increase in the number of sensilla, containing specific pheromone receptor neurons, in the last moult (Prillinger, Cell Tissue Res, 215:563-575, 1981; Chapman and Greenwood, Int J Insect Morphol & Embryol 15:83-96, 1986). The afferent neurons synapse with an increasing number of antennal lobe interneurons. Antennal lobe neurons increase either through multiplication or differentiation (Chambille and Rospars, Int J Insect Morphol & Embryol 14:203-226, 1985, and references therein). The observed difference in response characteristics between adult and nymphs could thus be related to the differences in the olfactory pathway.

In this study we investigated the structure and function of antennal lobe projection neurons (PNs) in the fifth instar of the desert locust. The nymphal PNs did not show any structural difference in neither innervation nor projection compared to adult insects. The projection neurons did, however show a different response spectrum compared to adults; up to now, neither blend-specific PNs nor any PNs responding specifically to the major component in the adult blend, have been found. The physiological characteristics of PNs thus reflect behavioural differences between 5th instar nymphs and adults. PNs responded to both behaviourally active aggregation pheromone components, identified in the nymphal faeces, and to oviposition pheromone components. Obeng-Ofori *et al.*, 1994) identified two components in the nymphal faeces. In addition to these two components the nymphal antennal lobe interneurons also responded to a third component, veratrole, which is found both in the adult male faeces and in the oviposition pheromone. We expect that also veratrole is of behavioural significance, possibly connected to the aggregation behaviour.

06-042

CENTRAL NERVOUS PROCESSING OF AGGREGATION
PHEROMONES IN DESERT LOCUSTSS. Anton and B.S. Hansson
Dept. of Ecology, Lund University, Lund, Sweden

Chemical cues are important for aggregation behaviour in the desert locust, *Schistocerca gregaria*. A number of aggregation pheromone components have been identified from the air surrounding adult male *S. gregaria*, and from the faeces of nymphs, whereas adult females seem not to produce aggregation pheromones. Adult male produced odours elicit aggregation behaviour only in adults, whereas nymphs respond only to nymphal volatiles (Torto *et al.*, Chem Ecol 20:1749-1762, 1994; Obeng-Ofori *et al.*, Entomol Exp Appl 73:85-91, 1994).

In this study we investigated the structure and function of antennal lobe interneurons, responding to single aggregation pheromone components and adult- and nymph-specific mixtures in adult males and females and in first instar nymphs of *S. gregaria*. The antennal lobe of adult *S. gregaria* contains over 1000 glomeruli which are arranged around a central fibre core. First instar nymphs have slightly fewer and smaller glomeruli. Single olfactory receptor neurons innervated several glomeruli within the antennal lobe. Projection neurons arborized in 10 to 25 glomeruli in adults and nymphs, and sent their axons to the protocerebrum. Projection neurons responded with different degrees of specificity to all behaviourally active aggregation pheromone components. Component-specific, blend-specific and generalist neurons were found in adults and first instar nymphs. In adults and nymphs most neurons responded to the adult male mix, but nymph mix-specific neurons were found too. The different behaviour of adults and nymphs is thus only partially reflected by the response characteristics of antennal lobe projection neurons.

MODULATION OF LEG JOINT STRAND RECEPTORS OF
LOCUSTA MIGRATORIA BY BIOGENIC AMINES

M. Eder, P. Bräunig

It has been shown in recent years that the responses of proprioceptors may be modulated by biogenic amines in various arthropod preparations. We are interested whether this also applies to insect strand receptors. Strand receptors are a special class of proprioceptive mechanoreceptors which are unusual because the somata of their sensory neurones are located in the central nervous system. In locusts, strand receptors are associated with appendages like antennae, mouthparts, and walking legs. In the legs there are four sense organs of this type associated with the subcoxal, the coxo-trochanteral, and the femoro-tibial joints.

Characteristically strand receptors span the joints in intimate association with power muscles. In the hind leg, for instance, the subcoxal receptor runs parallel to the anterior adductor muscle (M125), the two coxo-trochanteral receptors are embedded between the trochanteral levator muscles (M131, M132), and the strand of the femoro-tibial receptor runs parallel to the anterior accessory flexor muscle (M136b). Most, perhaps all these muscles are innervated by octopaminergic efferent DUM neurones. This agent might in principle reach the sensory dendrites of the strand receptor neurones by diffusion from synaptoid release sites in nearby power muscles. We therefore concentrate on studying possible effects of octopamine on strand receptor sensitivity, but other agents are being tested as well.

OCTOPAMINE MODULATES THE NEUROMUSCULAR MOTOR
PATTERN ASSOCIATED WITH STRIDULATION IN THE CRICKET,
Gryllus bimaculatus.Charles Habanananda and David Robinson
Dept of Biology, Open University, Milton Keynes, MK7 6AA, UK.

Calling stridulation in the male cricket, *Gryllus bimaculatus*, consists of coherent, well defined chirps which are rigidly organized into discrete groups of three to five pulses. Calling stridulation was induced in the cricket by applying a constant DC-current to the brain. The stridulatory motor pattern associated with calling was then characterized by recordings made from the antagonistic opener (M99) and closer (M90) muscles driving the elytra. The neuromuscular motor pattern was characterized according to two parameters: 1) The phase relationship between M99 and M90 and 2) The underlying rhythm being generated within and between muscles M99 and M90.

The injection of octopamine into the abdominal haemocoel of a restrained cricket was undertaken when the cricket was calling. An analysis of the effects of octopamine on the stridulatory motor pattern indicated that the phase relationship appeared to be severely disrupted, due to an increase in M99 and M90 burst durations. However, the stridulatory cycle period from opener to opener burst was not significantly altered. The additional muscle activity observed between the chirps, represented by rapid short and soundless contractions of the elytra, did not cause any disruption to the underlying rhythm being generated by the antagonistic muscles. Therefore, octopamine was disrupting the neuromuscular activity associated with stridulation by causing additional spiking activity within and between the chirps. However, no disruption to the generation of the stridulatory motor pattern itself was observed. These excitatory effects could have resulted from the action of the octopamine on either the muscle or the CNS or both. These results, taken in combination, indicated that octopamine has a general excitatory effect of the neuronal elements driving the stridulatory motor neurons.

06-045

CONTRIBUTION OF THE CAUDAL NERVOUS SYSTEM TO THE GENERATION OF STRIDULATORY MOTOR PATTERNS IN CRICKETS

David J. Robinson, Brian Milligan and Charles Habanananda
Dept of Biology, Open University, Milton Keynes, MK7 6AA, UK.

The central nervous mechanism responsible for the genesis of stridulatory motor patterns is widely accepted to reside within the pro- and mesothoracic ganglia alone. However, we describe the experimental evidence which demonstrates that more caudal neuronal structures are intimately associated with the generation of calling and aggressive song patterns in the house cricket, *Acheta domesticus*, and the field cricket, *Gryllus bimaculatus*.

Bilateral transection of the ventral nerve cord, in freely mobile crickets, revealed that neural input from the metathoracic ganglion is a prerequisite for song production. Furthermore, transection of the ventral nerve cord (VNC) between the metathoracic ganglion complex and the second free abdominal ganglion resulted in severe temporal disruption to acoustic behaviour.

Acoustic and electromyographical recordings of stridulatory activity from restrained crickets during song production elicited by direct brain stimulation, subsequently confirmed these data. The intimate association between stridulatory and ventilatory rhythms may provide an explanation for the abolition of patterned motoneuronal output following VNC transection immediately anterior to the metathoracic ganglion. The existence of interneurons, believed to originate within the metathoracic ganglion, which co-ordinate and command the ventilatory and flight motoneurons in the thoracic ganglia has been suggested for the locust. It is possible that such cells are present in the crickets, and serve to drive the stridulatory central pattern generator directly.

An apparent role for structures located caudal to the metathoracic ganglion, is however, more surprising. It is suggested that the rhythmic centre for song production is distributed over a wide region of the thoracic and abdominal CNS, and that the anterior abdominal ganglia perform a secondary, but nevertheless important role during pattern genesis, serving to stabilise thoracic stridulatory rhythms.

OLFACTORY CONDITIONING OF THE PROBOSCIS EXTENSION REFLEX IN *SPODOPTERA LITTORALIS*

(Lepidoptera: Noctuidae)

Ruey-Jane Fan, Peter Anderson and Bill S. Hansson

Department of Ecology, University of Lund, S-223 62 Lund, Sweden

Most female moths use olfactory cues to find host plants for oviposition. The knowledge is limited whether the moths' ability to recognise different odours is acquired or genetic. Thus, the aim of the present study was to investigate the learning ability of a noctuid moth. The proboscis extension reflex (PER) was used as an olfactory conditioning model. The moths were trained to associate a conditioned stimulus (CS, geraniol 100µg applied onto a piece of filter paper) with an unconditioned stimulus (US, 40% sucrose solution). Four experiments were conducted: (1) The effect of CS/US interval +10, +5, +3, +1, -3, -5 and -10s (+, - indicated that the CS was presented before and after US respectively) was tested after one-trial learning. A conditioned response (CR, conditioned PER) was established at the interval +3 to +1. (2) The moths were trained with 0, 1, 2, 4, 6, 8 or 10 trials. After 1 trial learning, 46.7% of the moths responded to the CS, and the CR increased up to 76.6% after 10 trials. (3) Two groups of moths were given either sucrose solution or water as the US in 10 trials learning. The CR to the sucrose solution was 76.5%, whereas that to water was 23.3%. (4) The moths were trained with different intertrial intervals (ITI). After 10 trials learning, the CR was 46.7%, 80% and 56.7% at the ITI 1, 5 and 10 min respectively. The results suggest that the moths do have a capability to associate an odour with a sucrose solution, and that the ITI and the CS/US interval are important factors in the conditioning process.

06-046

EVIDENCE FOR THE ROLE OF THE ACCESSORY MEDULLA AS CIRCADIAN PACEMAKING CENTER IN THE BRAIN OF ORTHOPTEROID INSECTS

M. Stengl, U. Homberg

Department of Zoology, University of Regensburg, Germany

Lesion studies have pointed to an area between the ventral medulla and the lobula as likely site of the circadian clock in cockroaches and crickets. This area is occupied by pigment-dispersing hormone-immunoreactive (PDH-ir) neurons, which innervate the accessory medulla (aMe), an appendage of the medulla. We investigated the organization of the aMe in locusts, crickets, and cockroaches, and present evidence for its possible role as a circadian pacemaker. In the cockroach *Leucophaea maderae* the aMe is not organized retinotopically. High concentrations of dense core vesicles in the aMe are matched by immunocytochemical localization of at least 7 partially colocalized neuropeptides. The aMe receives obviously dendritic as well as axonal innervation by PDH-ir neurons, which fulfill several morphological criteria for pacemaker candidates. Differences in the anatomy of the PDH-ir neurons may explain the differences in the coupling strength of the bilaterally paired pacemakers in crickets and cockroaches. After transection of both optic stalks the regeneration of PDH-ir processes to their original targets in the midbrain correlates with the regain of circadian locomotor activity. The intensity of PDH-immunostaining in the aMe shows a daily rhythm and injections of PDH into the optic lobe result in phase-dependent phase shifts of circadian wheel-running activity. Neurons of the aMe respond to photic stimuli and, in locusts are sensitive to polarized light. Taken together, these data support a role of the aMe as circadian pacemaking center in orthopteroïd insects. [Supported by DFG grants Ste 531 + Ho 950]

THE OLFACTO-CARDIAC RESPONSE AS A BIOLOGICAL MODEL FOR LEARNING AND MEMORY STUDIES

A.M. Angioy, P. Muronì, N. Piroddi, C. Reali, I. Tomassini Barbarossa
Dipartimento di Biologia Sperimentale, Sezione di Fisiologia Generale, Università degli Studi di Cagliari, Cagliari, Italia

In blowflies, olfactory stimuli can release the cardiac response of premature heart beat reversal, which has been described as a very sensitive indicator of sensory reception. Here we propose the paradigm of olfactory-induced cardiac response as a tool for testing the fly's ability to sense odours and learn and retain olfactory informations.

Adult *Protophormia terraenovae* blowflies were used. Electrophysiological recordings of heart activity (ECG) from the external body surface were performed on intact, restrained insects. Olfactory input was monitored (electroantennogram, EAG) simultaneously with ECG.

In learning tests, flies were trained to habituation by performing series of successive stimulations. Acquisition of habituation was measured as the number of effective stimulations needed to abolish the response. Memory formation was evaluated as the time required by flies trained to habituation in a first session of a stimulation series to show identical responsiveness in a second session of the stimulation series. Response dishabituation experiments were also performed and the dynamics of acquisition and retention of response dishabituation was determined.

DORSAL UNPAIRED MEDIAN NEURONES FORMING NEUROHAEMAL RELEASE SITES IN THE PERIPHERAL NERVOUS SYSTEM

P. Bräunig

Institut f. Zoologie, Technische Universität München, Garching, Germany

The efferent dorsal unpaired median (DUM) neurones represent a well-studied group of octopaminergic insect neuromodulatory cells. They are present in all ganglia of the central nervous system except the brain, they project bilaterally into the skeletal musculature, and have been shown to modulate neuromuscular transmission. The central branching pattern of numerous DUM neurones has been described in detail, but we know only very little about their peripheral branching patterns, and the target organs of individual DUM neurones are known in only a few cases.

One of the thoracic DUM neurones (DUM1B) innervates skeletal muscles, but also forms neurohaemal terminals on the surface of many peripheral nerves. DUM neurones forming such neurohaemal release sites are also found in the suboesophageal ganglion. They innervate antennal muscles but also the retrocerebral glandular complex. These results raised the question whether all efferent DUM neurones form such neurohaemal terminals in the periphery or whether this structural feature is unique for only a few such cells.

The results of a first survey (staining the well known DUM345, DUMETi and DUMDL neurones) indicate that neurohaemal ramifications appear to be a speciality of only a few DUM neurones. The thoracic DUM345 neurones establish a small neurohaemal area in only one particular peripheral location. No neurohaemal terminals were observed after staining DUMETi or DUMDL.

PILOCARPINE-INDUCED FEEDING MOTOR RHYTHMS OF THE ISOLATED SUBOESOPHAGEAL GANGLION OF *LOCUSTA MIGRATORIA*

G. Rast, P. Bräunig

Institut f. Zoologie, Technische Universität München, Garching, Germany

The muscarinic agonist pilocarpine has been shown to induce motor rhythms resembling those observed during locomotion in locusts and stick insects. We applied pilocarpine to the isolated suboesophageal ganglion (SOG) in order to find out whether this resulted in motor output similar to that observed in intact locusts during feeding. Our ultimate goal is to develop a preparation that allows us to study the interactions between neurones generating the feeding motor rhythm with intracellular methods, since this approach is impossible in intact insects because of the inaccessibility of the SOG.

Simultaneous recordings of mandibular opener and closer nerves on both sides show that pilocarpine (10^{-5} - $5 \cdot 10^{-4}$ M in the bath) elicits motor rhythms comparable to that observed in myogram recordings of the same muscles in intact feeding locusts: Opener units in both left and right nerves fire synchronously, but out of phase to the synchronously firing units in both left and right closer nerves. These rhythmic discharges during "fictive feeding" show much variability when compared to the motor rhythms observed in intact locusts. When comparing burst frequency and duration, however, rhythmic motor activity produced by the isolated ganglion often shows surprising similarities with the naturally occurring rhythms.

DIFFERENTIALLY EXPRESSED GENES IN THE CENTRAL NERVOUS SYSTEM OF *LOCUSTA MIGRATORIA* AND *SCHISTOCERCA GREGARIA*

M. Gewecke, F. Fehrmann, O. Franz, T. Roeder

Zoologisches Institut, Neurophysiologie, Universität Hamburg, Hamburg, Germany

The areas of the insect central nervous system (CNS; e.g. optic lobes, antennal lobes, mushroom bodies, thoracic ganglia) have different functions in information processing. This is based in part on the different molecular equipment of their neurons, e.g. within the optic lobes other receptor molecules are expressed than within the mushroom bodies. On the other side, also in single neurons signal cascades are no rigid processes. They can be modulated on every step, and thus be adapted to the respective requirements. Such modulations can have different time constants by which they are subdivided into short-term or long-term modulations. Both cases of functional adaptation, either the brain area specific or the long-term modulatory, are based on differentially expressed genes.

We investigate these differential gene expressions in the CNS of migratory (*Locusta migratoria*) and desert locusts (*Schistocerca gregaria*). In the first case mRNA is prepared from different areas of the CNS, and the reverse transcribed cDNA is analysed by the Differential Display-PCR (DD-PCR; Liang and Pardee, Science 257, 967-971, 1992). In the second case genes are activated by second-messenger analogous, and expressed in neurons from primary cultures. The cDNA produced from these cells is also analysed by the DD-PCR.

The results of these investigations show: (1) There is an area specific gene expression as well in the optic lobes, as in the dorsal protocerebrum with the mushroom bodies, or within the thoracic ganglia, where we find specific cDNA populations. (2) The expression pattern of the neurons from the primary cultures is changed in time, e.g. genes with different time constants are activated. Some genes are active only about 30 min after start of the experiment, others after about 4 h. This may have relevance to long-term modulation.

EFFECTS OF 20-HYDROXYECDYSONE AND DRUGS ON NEURONAL CELL DEATH IN THE CENTRAL NERVOUS SYSTEM OF *BOMBYX MORI* (LEPIDOPTERA)M. Kim, H. R. Kim¹

Korea Entomological Institute, Korea University

¹Department of Biology, Korea University, Seoul, Korea

In holometabolous insects, dramatic changes in external morphology from crawling larvae to flying reproductive adults are accompanied with changes in internal organs such as central nervous system and muscles. Especially the central nervous system undergoes neurometamorphosis involving neurogenesis, respecification of neuronal connectivity, and cell death. In this study, total numbers of neuron from last instar larvae to adults in *B. mori* abdominal ganglion (A3) were investigated to know the period of cell death. Two periods of cell death were present; the larva-pupal transition and the pupal-adult transition. To eliminate the ecdysteroid-secreting prothoracic glands in the thorax and interrupt descending neural pathway from the brain and thoracic ganglia, abdominal isolation was conducted. Neuronal cell death on abdominal ganglion (A3) was significantly delayed. To study the interaction between cell death and 20-hydroxyecdysone (20-HE), 20-HE was injected into lateral part of thorax every 12 hours for three days. To investigate this cell death is an active process, I tested the effects of RNA and protein synthesis inhibitor (Actinomycin D and Cycloheximide) on the survival of neurons.

University of Hyderabad, Hyderabad-500 046, India.

Protein phosphorylation is a post-translational modification that alters protein function and its interactions with other proteins, and is an important mechanism controlling nervous system function and development. *In vitro* phosphorylation of CNS (Central Nervous System) extracts from larval, pupal and adult *Bombyx mori* were carried out in the presence and absence of calcium and calmodulin. Polyacrylamide gel electrophoretic analysis followed by autoradiography revealed the phosphorylation of several proteins of which a 47 and 115 kDa polypeptides were the major phosphoproteins labelled with [^{32}P] in the absence of calcium. When the phosphorylation was performed in the presence of $CaCl_2$ (1 mM) there was a striking difference in the phosphorylation pattern of CNS proteins, two new polypeptides with molecular weights of 56 and 45 kDa were phosphorylated and there was an enhanced phosphorylation of the 115 kDa protein. Further 1 μ M calmodulin stimulated the phosphorylation of 56 and 45 kDa proteins by several fold.

Studies using the inhibitors of calcium dependent protein kinases revealed that KN-62, a specific inhibitor of Ca^{2+} /calmodulin-dependent protein kinase II inhibited the phosphorylation of the 56 and 45 kDa polypeptides by about 70%. Using calmodulin gel overlay and two dimensional gel electrophoresis we have putatively identified the phosphorylation of 56 kDa protein as Ca^{2+} /calmodulin kinase II autophosphorylation. *In vitro* culture of larval CNS in presence of JH I significantly stimulates the phosphorylation of 47 kDa protein. Degree of phosphorylation of the major phosphoproteins shows a distinct developmental profile. Further studies on the identification and characterization of these proteins may provide insight into their physiological function during neurometamorphosis.

DEVELOPMENTAL CHANGES OF LOCUSTATACHYKININ-1-IMMUNOREACTIVE NEURONS IN POSTEMBRYONIC CENTRAL NERVOUS SYSTEMS OF THE COMMON CUTWORM, *SPODOPTERA LITURA*

H. O. Kang, D. W. Kwon, W. K. Kim, B. H. Lee
Department of Biology, Korea University, Seoul, Korea.

Antiserum raised against the neuropeptide locustatachykinin-1 (LomTK-1) were used to investigate developmental changes in LomTK-1 containing neuron in postembryonic central nervous systems of the common cutworm, *Spodoptera litura*. In the brain of 1st instar larva, 4 pairs of locustatachykinin-1-immunoreactive(LomTK-IR) neurons was detected. In the developmental stages from the 1st instar larva to the 5th instar larva, the number of LomTK-1-IR neurons gradually increases, especially to 45 pairs. During the metamorphic changes from prepupa to pupa, the number of LomTK-1-IR neurons gradually decreased from 21 pairs to 12 pairs, and then abruptly increases to about 45 pairs in the 7-days-old pupa and the adult. The LomTK-1-IR neurons in all the developing brains supply their nerve processes to most brain neuropils, and 2 pairs of LomTK-1-IR nerve fibers are running into all the ventral ganglia. The suboesophageal ganglion, which has been separated from brain, is incorporated to the brain during development from prepupa to 1-day-old pupa, thereby forming cerebro-suboesophageal complex. The 2nd thoracic ganglion in the 1st instar larva has 1 pair of LomTK-1-IR neurons, while 2nd and 3rd thoracic ganglia of 2nd instar larva contain 1 pair and 3 LomTK-1-IR neurons, respectively. However, LomTK-1-IR neurons are included in all the ventral ganglia from the 3rd instar larva to the adult. In each ventral ganglion, the number of LomTK-1-IR neurons gradually increase from the 1st instar larva to the 5th instar larvae, and then decrease from the 6th instar larva to the adult. All the ventral ganglia contain 2 pairs of LomTK-1-IR nerve fibers which are running from the brain to the terminal abdominal ganglia.

06-054

IMMUNOCYTOCHEMICAL MAPPING OF SEROTONERGIC NEURONS IN CENTRAL NERVOUS SYSTEMS OF THE COMMON CUTWORM, *SPODOPTERA LITURA* DURING POSTEMBRYONIC DEVELOPMENT

H. O. Kang, G. S. Kim, B. H. Lee
Department of Biology, Korea University, Seoul, Korea.

This study has been carried out to investigate the postembryonic development of neural network of serotonin-immunoreactive(5-HTi) neurons in the brain and ventral ganglia of the common cutworm, *Spodoptera litura*. The brains of 3rd instar and 4th instar larvae contain about 26 pairs of 5-HTi neurons, which are located in medial and marginal regions of them. The 6th instar larval brain includes about 24 pairs of 5-HTi neurons which are evenly distributed in it. The 5-HTi nerve processes are mainly intrinsic to the brains. 5-HTi neurons are included as about 14 pairs in suboesophageal ganglion, as about 11 pairs in three thoracic ganglia, and two to five 5-HTi neurons in each abdominal ganglia, in which the number and distribution pattern of 5-HTi neurons and nerve processes are very similar without regard to developing larval stages. In all the larval stages, a pairs of 5-HTi nerve fibers, which run down in parallel, project from the brain to the terminal ganglion. The brains, which have been developed into pupal stage, have less 5-HTi neurons(about 33 pairs) in early pupal stage. The 5-HTi nerve fibers has been also reduced in number. They form about two 5-HTi commissural nerve fiber bundles, which are innervated into contralateral cerebral neuropils, show rich arborizations. In adult, 5-HTi neurons abruptly increase in number to about 83 pairs. The 5-HTi nerve processes are also mostly intrinsic to brain. But some of them are extrinsic to the ventral ganglia.

06-056

POSTEMBRYONIC DEVELOPMENT OF LEUCOKININ-1-IMMUNOREACTIVE NEURONS IN CENTRAL NERVOUS SYSTEMS OF THE COMMON CUTWORM, *SPODOPTERA LITURA*

H. O. Kang, D. W. Kwon, Y. K. Lee¹, B. H. Lee
Department of Biology, Korea University, Seoul, Korea.
¹ Korean Entomological Institute, Korea University, Seoul, Korea

The developmental changes of leucokinin-1-immunoreactive(LK-1-IR) neurons in the postembryonic central nervous systems(CNS) of the common cutworm, *Spodoptera litura*, were investigated by using antiserum that was raised against leucokinin-1(LK-1). The whole-mount immunocyto- chemistry in developing CNS has demonstrated that LK-1-IR neurons exist as 2 pairs in the brain of 2nd instar larva, and then gradually increase in number to 16 pairs in the brain of 5th instar larva. The LK-1-IR nerve processes found from the 2nd instar larva to the 5th instar larva are mostly intrinsic to the brain. However, 2 pairs of LK-1-IR nerve fibers run through all the ventral ganglia. While the brain of the 6th instar larva has 13 pairs of LK-1-IR neurons, the brains of prepupa, 1-day-old, 3-days-old, 5-days-old, and 7-days-old pupae contain just 2 or 3 pairs of LK-1-IR neurons. The adult brain has 6 pairs of LK-1-IR neurons. After the pupation, the LK-1-IR nerve processes abruptly decrease, due to the reduction in number of LK-1-IR neurons. In case of the ventral ganglia, 1st instar larva possesses 2 pairs of LK-1-IR neurons in the 3rd thoracic ganglion and 1 pair each in 3rd, 4th, 5th and 6th abdominal and terminal ganglia. In 2nd and 3rd instar larvae, additionally 2 pairs and 3 pairs of neurons appear in abdominal ganglia, respectively. The number and localization of the LK-1-IR neurons is very similar from the 3rd instar larva to the prepupa. There is no in the larval stages. During metamorphosis from the prepupa to the adult, the number and distribution of the LK-1-IR neurons showed similar patterns in all ventral ganglia. The LK-1-IR nerve processes in the ventral ganglia of all postembryonic developmental stages are mostly projecting to neurohemal organs, but intrinsic nerve fibers are also found.

ACCUMULATION OF PEPTIDE NEUROHORMONES IN PARASITIZED CATERpillARS: IDENTIFICATION OF FLRFamide PRECURSORS

T.G. Kingan, D. Zitnan¹, D.F. Mierke², N.E. Beckage³
 USDA ARS Insect Neurobiology and Hormone Laboratory
 Beltsville, MD USA - ¹ Institute of Zoology, Slovak Academy
 of Sciences, Bratislava, Slovakia - ² Department of Chemistry,
 Clark University, Worcester, MA USA - ³ Department of
 Entomology, University of California, Riverside, CA USA

We have shown that parasitization of *Manduca sexta* by the braconid wasp *Cotesia congregata* leads to an accumulation of immunoreactive peptides, both in the endocrine cells of the midgut and in neurosecretory cells of the CNS. This raises the possibility that one consequence of parasitization is a general block in release of peptide hormones, including those associated with development. We have exploited this accumulation to isolate and sequence two new FLRFamides from the midguts of parasitized *M. sexta*. These peptides, 24 and 39 amino acids in length (F24, F39), have the sequence KRQDVVHSFLRFamide at their C-termini; thus, they have the characteristics expected of a pro-hormone for a peptide (pEDVVHSFLRFamide) previously identified from the CNS. Preliminary data suggest that F24 and F39 are also present in the CNS, thus supporting their presumptive roles as prohormones. Interestingly, the decapeptide was not found in the midgut, suggesting that F24 and F39 themselves may function as endocrines or paracrine from the midgut. Earlier studies showed that the decapeptide could be distinguished in its action on visceral muscle from two heptapeptide FLRFamides (GNSFLRFamide, DPSFLRFamide) also isolated from *M. sexta* CNS. To determine whether a structural basis exists for these findings, we have used two-dimensional nuclear magnetic resonance to investigate the secondary structures of the *M. sexta* FLRFamides. We find that the heptapeptides do not exhibit secondary structure in solution, but that the decapeptide does, forming a γ -turn about His⁵-Phe⁷.

06-058

NEURAL INACTIVATION OF SEX PHEROMONE PRODUCTION AFTER MATING IN THE SILKWORM MOTH, *BOMBYX MORI*

T. Ichikawa

Department of Biology, Faculty of Science, Kyushu University, Fukuoka, Japan

The production of sex pheromone in the moth is under the control of a pheromonotropic factor, pheromone biosynthesis-activating neuropeptide (PBAN). Neurosecretory cells with immunoreactive PBAN have a soma in the subesophageal ganglion (SG) and project an axon to the corpus cardiacum (CC) via a branch of the maxillary nerve.

A virgin female of the moth has a large amount of sex pheromone in the pheromone gland. After mating, pheromone titer declined with a time course closely resembling that of decapitated females. The inactivation of pheromone production after mating was prevented when the ventral nerve cord was transected before mating. In contrast, the post-mating inactivation of pheromone production was not prevented when the ventral nerve cord was cut 1 h after the initiation of mating. Although females produced only a small amount of pheromone when the connection between the brain and the SG was cut at an early pupal stage, mating did not induce a significant decline of pheromone production in such females. When connection between both hemispheres of the brain of a virgin female was cut, pheromone titer declined to near zero without mating.

The results suggest that (1) mating may induce a complete shut down of the release of the pheromonotropic factor from the CC at an early stage of copulation, (2) the brain has a neural mechanism that activates the putative PBAN producing cells in the virgin female, (3) inactivation of pheromone production after mating is mediated by a neural signal that travels up the ventral nerve cord to the brain-SG complex to switch off the neural mechanism.

06-059

BRAIN FACTORS CONTROLLING DIAPAUSE HORMONE RELEASE FROM THE SUBESOPHAGEAL GANGLION OF THE SILKWORM, *BOMBYX MORI*

C. C. Wu and K. Suzuki

Department of Applied Bioscience and Technology, Faculty of Agriculture, Iwate University, Morioka 020, Japan

Bombyx embryonic development is arrested at the late gastrula stage in response to the peptidic diapause hormone (DH) secreted from the subesophageal ganglion (SG) in young pupae of diapause egg producers. DH acts upon the oocytes of diapause egg producers and alters their developmental program. Although DH's amino acid sequence and gene structure were determined, the regulation of DH secretion in pupal brains has remained a mystery for a long time.

Free nucleotides in pupal brains were examined in a bivoltine race (Daizo), using high pressure liquid chromatography (HPLC). Concentrations were nearly the same level as observed in rat brains. Major differences in monophosphates, diphosphates and triphosphates of purine and pyrimidine nucleotides, and an unidentified nucleotide derivative were observed between silkworms which were exposed to regimens of continuous light and warm conditions (27°C) and those exposed to continuous darkness and cold conditions (15°C) throughout maternal embryonic development. In particular, concentrations of ADP, ATP, GDP, GTP, IDP, ITP, UDP and UTP, were more abundant in the pupal brains of insects exposed to continuous light and warm conditions. When brain-subesophageal ganglion complexes from non-diapause egg producers were cultured with mixtures of nucleotides, the resulting culture medium was highly effective in eliciting diapause in non-diapause egg producers.

On the other hand, using capillary SDS gel electrophoresis of pupal brain extracts, we found significant differences between diapause egg and non-diapause egg producers. The brain extract of diapause egg producers also induced *in vitro* secretion of a diapause hormone-like material from the brain-subesophageal ganglion complexes of the non-diapause egg producers. These results suggest that the phosphorylating enzymes of brain nucleotides and the brain peptides have a role in diapause induction.

06-060

LOCALIZATION OF ALLATOTROPIN IN THE BRAIN AND GANGLIA OF THE HAWKMOOTH, *AGRIUS CONVULVULI*

T. Kamito, A. Mizoguchi¹, S. Nagata², K. Kojima² and H. Kataoka².

Department of Biology, International Christian University, Mitaka, Tokyo, Japan - ¹Department of Biology, Nagoya University, Chikusa, Nagoya, Japan - ²Department of Biotechnology, University of Tokyo, Bunkyo, Tokyo, Japan

Allatotropin (AT) is a neurosecretory peptide that stimulates juvenile hormone secretion in the corpora allata of the insect. However, AT appears to be active only in adult Lepidoptera and has no effect on larvae or on species in other orders. Therefore, to clarify the role of AT, the localization of AT peptides and gene transcripts in the nervous system of the hawkmoth, *Agrius convolvuli*, were investigated by immuno-histochemistry and *in situ* hybridization.

Immunohistochemical investigations with a monoclonal antibody against synthetic AT revealed that AT peptides were present in many cells of the brain and the frontal, subesophageal and prothoracic ganglia.

DIG-labeled DNAs and RNAs were synthesized from the AT cDNA and used as hybridization probes. After *in situ* hybridization on whole mount and sectioned brain samples, several cells were positively labelled.

06-061

CARBACHOL-INDUCED PROTEIN PHOSPHORYLATION IN THE BRAIN-CORPUS CARDIACUM- CORPUS ALLATUM COMPLEX OF THE SILKWORM, BOMBYX MORI.

Y. Shirai and Y. Aizono*

The Graduate School of Science and Technology, and *Faculty of Agriculture, Kobe University, Kobe, Hyogo 657, Japan.

As to the control of PTTH release, we have so far found that carbachol (acetylcholine agonist) induces PTTH release via the muscarinic acetylcholine receptor, and that protein kinase C (PKC) and calcium/calmodulin-dependent protein kinase (Ca²⁺/CaM PK) are involved in carbachol-induced signal transduction. These findings suggest that protein phosphorylation is important for PTTH release. Accordingly, carbachol-induced protein phosphorylation in the brain-corpus cardiacum-corpus allatum complex, in parallel to carbachol-induced PTTH release, was examined.

Phosphorylations of approximately 32 kD, 25 kD and 21 kD proteins were depended on the carbachol concentrations in the range of 10 μM - 1 mM, and occurred within 5 min. The time- and dose-dependency of these phosphorylations were consistent with those of the carbachol-induced PTTH release. Furthermore, the 25 kD protein seemed to be phosphorylated by PKC, while Ca²⁺/CaM PK might phosphorylate the 21 kD protein.

Consequently, the good correlation between the carbachol-induced protein phosphorylations and the carbachol-induced PTTH release suggest that the 25 kD and 21 kD phosphorylated proteins, at least, should play important role in carbachol-induced PTTH release. We are exploring the function of phosphorylated proteins in PTTH release.

06-063

IMMUNOCYTOCHEMISTRY OF A NOVEL INSECT GABA RECEPTOR SUBUNIT

K. Aronstein, R. H. French-Constant. Departments of Neuroscience and Entomology, University of Wisconsin-Madison, Madison, Wisconsin, USA

Following our recent cloning of a novel γ-aminobutyric acid (GABA) receptor subunit gene *Resistance to dieldrin* or *Rdl* from the cyclodiene resistance locus in *Drosophila melanogaster*, we were interested in defining its pattern of expression during development. Here we report the raising of an anti-*Rdl* polyclonal antibody that recognizes a single protein of the expected 65 kDa size in immunoblots of *Drosophila* head homogenates. *In situ* hybridization using *Rdl* cDNA probes and the anti-*Rdl* antibody shows that *Rdl* message and protein are expressed globally in the developing central nervous system (CNS) of 15-17 hr embryos. No message can be observed on or before 12-13 hr. Interestingly, despite the use of GABA in both the peripheral and CNS of insects, *Rdl* GABA receptor subunits appear to be confined to the CNS. Detailed immunocytochemistry of *Drosophila* brain sections showed particularly strong anti-*Rdl* antibody staining in the optic lobes, ellipsoid body, fan shaped body, ventrolateral protocerebrum and the glomeruli of the antennal lobes. Results are compared with the distribution of staining observed in the insect CNS with antibodies against GABA itself, synaptotagmin (a synaptic vesicle protein) and a second *Drosophila* subunit which appears to be a homolog of the vertebrate GABA_A receptor β subclass.

06-062

LIGAND-SPECIFIC COUPLING OF A NOVEL CLONED DOPAMINE RECEPTOR FROM *DROSOPHILA MELANOGASTER* WHEN EXPRESSED IN *XENOPUS* OOCYTES.

V.Reale, F.Hannan, G.Feng¹, L.M.Hall¹, P.D.Evans

The Babraham Institute Laboratory of Molecular Signalling, Dept. of Zoology, University of Cambridge, Cambridge, UK - ¹ Dept. of Biochem. Pharmacology, State University of New York, Buffalo, USA.

In insects dopamine receptor subtypes may be involved in memory and learning. Dopamine receptors belong to the G-protein coupled receptor superfamily of seven transmembrane domain proteins. Five distinct classes of dopamine receptor have been identified by cloning in mammals. These fall into two broad pharmacological categories D1-like and D2-like. A D1-like receptor affecting adenylyl cyclase activity has already been identified in *Drosophila* (Gotzes et al., 1994; Sugamori et al., 1995). We have recently cloned a novel G-protein coupled dopamine receptor (DopR99B), expressed in *Drosophila* heads, which may define a novel class of dopamine receptors.

We report here that when expressed in *Xenopus* oocytes the activated DopR99B increases intracellular Ca²⁺ levels and also increases cyclic AMP levels. The rank order of potency for biogenic amines in stimulating both second messenger effects is dopamine > norepinephrine > epinephrine > tyramine. Octopamine and 5-hydroxytryptamine are not active at concentrations up to 100 μM. The pharmacological profile for synthetic antagonists on both second messenger responses was identical and suggested that DopR99B is a D1-like dopamine receptor. The pharmacological profile for synthetic agonists again suggests a D1-like dopamine receptor, but was different for the two second messenger systems assayed.

Thus, DopR99B exhibits ligand-specific coupling to different second messenger pathways, a phenomenon exhibited by a range of other aminergic and peptidergic G-protein coupled receptors from both invertebrates and vertebrates (Robb et al 1994; Evans et al 1995). This suggests that the receptor exhibits a different agonist profile for synthetic ligands depending upon which second messenger systems are assayed.

06-064

NEUROTRANSMITTER TRANSPORTERS IN INSECTS: ISOLATION, CHARACTERIZATION AND PHARMACOLOGY OF THE γ-AMINO BUTYRIC ACID (GABA) TRANSPORTER IN *MANDUCA SEXTA*.

D. Mbungu¹, C. S. Chiu, A. K. Pullikuth, L. S. Ross, S. S. Gill, Department of Entomology, University of California, Riverside, CA, USA, -¹Department of Biology, University of East Africa, Eldoret, Kenya.

Synaptic transmission termination occurs by several mechanisms including the uptake of the neurotransmitter molecules into the presynaptic neuron by specialized plasma membrane transport proteins. We have cloned a (DABA)-sensitive GABA transporter and a novel transporter from a cDNA library from *Manduca sexta* embryo. The GABA transporter cDNA clone, MasGAT, has high sequence homology to known mammalian GABA transporters. The MasGAT transcript is about 5.5kb with an open reading frame (ORF) of 1793bp, while that of the novel transporter is 4.9kb with an ORF of 2181bp. Injection of a 2.2kb cRNA from this clone into *Xenopus* oocytes results in ³H-GABA transport, while the transport of the novel transporter is under investigation. Michaelis-Menten kinetic analysis shows that GABA transport occurs by a high affinity and saturable process suggesting that it is carrier-mediated. Ion substitution studies also show the transport process to be highly dependent on extracellular Na⁺ gradient, a finding that is consistent with properties of known mammalian neurotransmitter transporters. Although MasGAT shares certain pharmacological similarities with known mammalian GABA transporters this transporter has pharmacologically distinct from the known mammalian GABA transporters.

Section 7

Insect Immunity

07-002

IMMUNE RECOGNITION AND REACTIVITY IN *DROSOPHILA*

A. J. Nappi

Department of Biology, Loyola University, Chicago, IL USA

Although various cellular and biochemical effector responses have been well documented for many insects, comparatively little is known of the molecular mechanisms underlying the prefatory non-self recognition response, or of the nature, specificity and mode of action of the killing molecules. The *Drosophila*-wasp parasitoid system provides unique opportunities to examine the interactions between immune competent and susceptible host strains with resistant and susceptible strains and species of parasitoids. Immune reactivity in this host is manifested in part by the proliferation, differentiation, mobilization, aggregation and adhesion of hemocytes to form multilayered capsules around parasitoids. Eumelanin forms on the surface of the foreign object and among the hemocytes comprising the innermost layers of the capsule. Immune capacity in *Drosophila* infested by the wasp *Leptopilina boulardi* is due to a single dominant allele located on the second chromosome. This trait is strain and species specific, with separate alleles encoding recognition of different parasitoid species. Immune capacity is severely compromised in mutants deficient in dopa decarboxylase, suggesting the pathway involving the synthesis and oxidation of dopamine is essential for killing parasitoids. Implicated as cytotoxic molecules in *Drosophila* cellular immunity are quinoid precursors of eumelanin and/or certain reactive oxygen species generated during melanogenesis. The identity of the non-self recognition mechanism(s) triggering the effector responses has not been established. What appears to be essential for a non-self recognition process is a system of communication among hemocytes that potentiates their collaborative interactions with foreign entities. Non-self discrimination and collaborative hemocytic interactions with parasitoids may involve cell adhesion molecules (e.g., integrins, laminins, proteoglycans), regulatory polypeptides (cytokines), and/or agglutinins (lectins).

07-001

RECOGNITION OF NON-SELF IN INSECT IMMUNITY - THE RELATIVE ROLES OF HAEMOLYMPH LECTINS AND COMPONENTS OF THE PROPHENOLOXIDASE CASCADE

N.A. Ratcliffe and C. Chen

Biomedical and Physiological Research Group, School of Biological Sciences, University of Wales Swansea, Swansea. SA2 8PP, Wales, U.K.

Recent experiments indicate, unequivocally, that haemolymph lectins of insects function in the recognition and clearance of foreign invaders from the circulation, as well as important determinants of parasite colonization of vector species. Work in the cockroach, *Blaberus discoidalis*, has shown the presence of multiple lectins with differing specificities capable of recognising a range of microorganisms. Purification, characterisation and sequencing of these molecules has revealed structural and functional similarities to the mannose-binding proteins of vertebrates, which activate complement during innate immunity in these animals. Apart from the lectins, other factors generated during activation of the prophenoloxidase in insects also appear to function in the identification of non-self and mediation of the cellular defences.

The evidence for the relative roles of the lectins and of components of the prophenoloxidase cascade in insect immunity is discussed and a model for their possible interaction in the cellular defence reactions is presented.

07-003

THE PURIFICATION AND POSSIBLE ROLE OF TWO LECTINS ISOLATED FROM *RHODNIUS PROLIXUS* - THE VECTOR OF SOUTH AMERICAN TRYPANOSOMIASIS (CHAGAS' DISEASE)

Y. Nigam¹, N.A. Ratcliffe¹, C.B. Mello², P. Azambuja², E.S. Garcia²

¹Biomedical and Physiological Research Group, School of Biological Sciences, University of Wales Swansea, Swansea. SA2 8PP, Wales, U.K.

²Department of Biochemistry and Molecular Biology, Fundacao Oswaldo Cruz, Av. Brasil 4365, Manguinhos, Rio de Janeiro, BRASIL.

Lectins are known to have a wide range of important biological functions. Recently, several studies in haematophagous insect vectors, such as tsetse flies and blackflies, have shown that lectins, present in the midgut and/or haemolymph of the insect, may play a part in the establishment of parasitic infections in the host.

In this paper, we present the results of the purification and characterisation of a crop agglutinin and a haemolymph lectin isolated from *Rhodnius prolixus*, the vector of South American trypanosomes. We offer preliminary *in vivo* and *in vitro* evidence to suggest that the purified lectins may be implicated in the development and maturation of these trypanosomes.

07-004

IDENTIFICATION OF INDUCIBLE SERINE PROTEASES OF *SIMULIUM DAMNOSUM* S.L. (DIPTERA: SIMULIIDAE) FOLLOWING AN *ONCHOCERCA OCHENGI* (NEMATODA: FLIARIOIDEA) INFECTION USING TARGETED DIFFERENTIAL DISPLAY

H.E. Hagen, S.L. Klager, J.H. McKerrow, P.J. Ham

Centre for Applied Entomology and Parasitology, Department of Biological Sciences, Keele University, Staffordshire ST5 5BG, UK - 1 Laboratory of Molecular Pathology, Veterans' Administration Medical Center, University of California at San Francisco, CA 94121, USA

One of the earliest visible changes in the haemolymph of *Onchocerca* infected *S. damnosum* s.l., the most important vector of human and bovine onchocerciasis in West-Africa, is the appearance of phenoloxidase. As in other insects it could be shown that this enzyme has to be activated by serine proteases. In order to identify inducible proteases in infected *S. damnosum* s.l. we used Differential Display Reverse Transcription PCR (DDRT-PCR) using homology based generic primers. So far three serine protease have been clearly identified, one of which represents a trypsin like molecule. Based on recent sequence information of the cleavage site of prophenoloxidase from other arthropods this type of protease is likely to be involved in the cleavage of the pro-enzyme. At the moment we are in the process of characterizing the cleavage site of *S. damnosum* s.l. prophenoloxidase using 5' RACE-PCR following the successful cloning of prophenoloxidase-like DDRT-PCR-derived products to prove whether or not this is also the case for *S. damnosum* s.l. In the future it is envisaged to use recombinant active serine proteases for *in vitro* and *in vivo* tests to study the activation of prophenoloxidase in *S. damnosum* s.l.

07-006

REGULATORY AND FUNCTIONAL ASPECTS ON HEMOLIN, AN INSECT IMMUNE PROTEIN OF THE IMMUNOGLOBULIN SUPERFAMILY (IgSF)

L. Faye, R. Bettencourt, K. Roxström Lindquist, H. Lanz Mendoza¹, Marco Fabbri², Ingrid Lindström Dinné³, S. Daffre Pereira⁴

Department of Genetics, Stockholm University - 1 Institute of Plant Sciences, Applied Entomology, ETH-Zentrum/NW, Zurich, Switzerland - 2 III^o Faculty of Science University of Milan, Varese, Italy - 3 Department of Medical Biochemistry, The University of Calgary, Calgary, Canada - 4 Parasitologia - ICB University of Sao Paulo, Sao Paulo, Brasil

Hemolin was first identified in the giant silkworm, *Hyalophora cecropia*, as an immunoglobulin-related molecule involved in immune response. It is present at low levels in the naive insect, and strongly upregulated by bacterial infection, lipopolysaccharides (LPS) or phorbol ester (PMA), and also slightly by wounding.

By UV-cross linking experiments, hemolin was shown to bind to *E. coli* LPS. This binding could be competed by Lipid A, indicating its specificity of binding to Gram-negative bacteria. Pure hemolin inhibits hemocyte aggregation, a finding that can be explained by the recently identified membrane form of hemolin and by the homophilic binding properties of soluble hemolin. Moreover, hemolin was shown to enhance phagocytosis of yeast by both hemocytes and *Drosophila* mbn-2 cells. The phagocytic activity was further increased by addition of LPS. This activity was correlated with increased protein kinase C phosphorylation, which in turn could be inhibited by PKC inhibitors.

The *Hemolin* gene organization shares features with cell adhesion molecules of the IgSF. κB-motifs are found in one of the introns as well as in the upstream region. These regions did however not confer LPS induction in transfection assays.

07-005

RECOGNITION OF NON-SELF IN INSECT IMMUNITY - MODULATION OF IMMUNE REACTIONS BY OPSONIZATION

P. Götz and A. Wiesner

Institute of Zoology, Free University of Berlin, Berlin, Germany.

Mechanisms responsible for opsonic effects have been studied in our laboratory. Phagocytosis of FITC-labelled yeast by isolated plasmatocytes (PL) from *Galleria mellonella* larvae significantly increased after preincubation of yeast cells in cell free haemolymph (= plasma). The portion of phagocytically active PL was enhanced from about 5% to 30-40%. Yeast cells opsonized in plasma from *G. mellonella* were phagocytosed at higher rates also by haemocytes from other arthropods (*Agrotis segetum*, *Zophobas adactylus*, *Astacus astacus*) and by so-called "Gäuff cells", a blood tumor cell line from *Drosophila melanogaster*, indicating a certain universality of the haemocyte-opsonin interaction.

Several molecules acting as opsonins in the haemolymph of *G. mellonella* have been recognized. One of these was found to be Apolipoprotein III (ApoLpIII), another proved to be a component of the prophenoloxidase activating system and one is a prostaglandin-like molecule. RGD-dependent cell adhesion of ApoLpIII has been demonstrated (Wiesner et al., submitted), it is also known that such cell adhesion proteins function in crustaceans (Thörnqvist et al., 1994). In addition to its opsonic effect, ApoLpIII acts also as a stimulator of cell activity and induces neosynthesis of antimicrobial peptides.

Granular cells (GR) represent the most probable source for opsonic material because this type of blood cell reacts by exocytosis upon contact with foreign substrates and extrudes material which sticks to the foreign surfaces. Monoclonal antibodies specific to GR have been prepared to stain such material and to block its opsonic capacity. Possible mechanisms of immune modulation by opsonization are discussed.

07-007

DETECTION AND CHARACTERIZATION OF AN INDUCIBLE METALLO-PROTEASE-INHIBITOR IN *GALLERIA MELLONELLA*

M. Wedde¹, A. Vilcinskis¹, P. Kopacek², P. Götz¹

¹ Institut für Zoologie der Freien Universität Berlin, Germany

² Galena Co., Research unit, Ceske Budejovice, Czech Republic

Protease inhibitors are presumed to play an important role in inhibiting undesired proteolytic activity of enzymes released by invading pathogens. Several protease inhibitors have been described in hemolymph and cuticle from different insects, but an inhibitory activity against metallo-proteases was never reported before. Insect pathogens e.g. the entomogenous fungi *Metarhizium anisopliae* and *Beauveria bassiana* are known to produce metallo-proteases among other proteolytic enzymes during infection. Within the hemolymph of the Greater Wax Moth *Galleria mellonella* we demonstrated for the first time the occurrence of an metallo-protease-inhibitor in insects. It strongly inhibited thermolysin but not trypsin or elastase activity. In contrast to trypsin- or elastase inhibitory activity thermolysin inhibition was only detectable after intrahemocoelomic injection of provokers like zymosan, yeast cells or *M. anisopliae* and *B. bassiana* blastospores. The time dependant increase of metallo-protease-inhibitory activity in cell free hemolymph after injection was correlated with the lysozyme and antibacterial activity measured with inhibition zone assays, suggesting the release of an inhibitor during humoral immune response. For the detection and characterization of the metallo-protease-inhibitor we used a modified azocoll-assay and thermolysin as a sorbent for purification. The metallo-protease-inhibitor was resistant to heat treatment up to 100°C and to trichloric acid precipitation and it was not retained by ion exchange- or blue sepharose-columns.

CELL-CELL COOPERATION IN RECOGNITION AND ENCAPSULATION OF FOREIGN TARGETS BY INSECT HEMOCYTES

M. R. Strand, L. Pech, J. A. Johnson

Department of Entomology, University of Wisconsin-Madison, Madison, Wisconsin, USA

Haemocytes play an essential role in defending insects against pathogens and parasites that enter the haemocoel. A primary defense response is encapsulation; a process in which haemocytes attach to the foreign organism and kill it. Whether encapsulation requires cooperation between specific subpopulations of haemocytes is unknown. Using monoclonal antibodies specific to different subpopulations of haemocytes, we investigated the process of capsule formation in the moth *Pseudoplusia includens*. Immunocytochemical staining demonstrated that capsule formation began when granular cells attached to the foreign target. This was followed by attachment of multiple layers of plasmatocytes. Termination of capsule formation occurred when a subpopulation of granular cells formed a monolayer around the periphery of the capsule. In vitro encapsulation assays revealed that neither granular cells nor plasmatocytes were capable of forming a capsule independently. However, plasmatocytes would encapsulate targets if granular cells were present or if targets were preincubated in medium conditioned by granular cells. Biochemical mediators involved in recognition of foreign targets and cell-cell adhesion during capsule formation are discussed.

PROTEINASE INHIBITORS OF THE MOSQUITO *Aedes aegypti*, PART OF THE IMMUNE SYSTEM?

E. Hörler & H. Briegel

Zoologisches Institut der Universität Zürich, Zürich / Switzerland

In *Aedes aegypti*, proteinase inhibitors are present in all developmental instars and are even enhanced in blood-fed females. This led to the assumption of suppressed chymotryptic activity during blood digestion. In blood-fed females, inhibitor activity against chymotrypsin was twice that of sugar-fed females. This inhibitory activity was localized mainly in the fat body, some of it in maturing oocytes, and was only marginal in the midgut.

Aedes aegypti chymotrypsin inhibitor (AACI) was isolated and purified by HPLC, revealing an extremely thermo- and pH-stable peptide with a molecular mass of 5.75 kD, established by mass spectrometry.

AACI activity was active against proteinases of different mosquito species as well as against bovine α -chymotrypsin and trypsin, but not against subtilisin, pancreatic elastase, nor fungal proteases. AACI did not interfere with bacterial growth.

The amino acid sequence of AACI showed 50-55% identity with small serine proteinase inhibitors from *Locusta migratoria*, which are known to be involved in the regulation of the prophenoloxidase (PPO) activation cascade.

In conclusion, the hypothesis of AACI as a regulator of chymotrypsin during blood digestion is abandoned; instead we assume a functional role in the mosquito immune system.

Supported by the Swiss National Science Foundation.

ANTIMICROBIAL PEPTIDES IN INSECTS : A BIOCHEMICAL AND PHYLOGENETIC STUDY.

Philippe BULET, Charles HETRU and Jules A. HOFFMANN

Institut de Biologie Moléculaire et Cellulaire UPR 9022 du CNRS, 15 rue René Descartes, Strasbourg Cedex, FRANCE.

The immune defense of insects against microorganisms involves cellular and humoral effector mechanisms. The humoral defense facet is characterized by the rapid appearance in the hemolymph of a battery of potent antimicrobial substances. These molecules are synthesized in the fat body in response to a microbial challenge and released into the blood where their respective concentrations range between 1 μ M and 100 μ M. Since the characterization in 1981 by Boman and associates of the cecropins, more than 100 structures have been reported. We have isolated from various insect species over 60 of these molecules. They are small cationic peptides which can be classified into four distinct families : cecropins (linear molecules without cysteines forming amphipathic helices), cyclic peptides (peptides with one to four intramolecular disulfide bridges), proline-rich peptides (with or without an O-glycosylated substitution) and glycine-rich peptides. Among the molecules which we have characterized, four are of particular interest. (1) Drosocin, which has been isolated from *Drosophila melanogaster*, is the first antibacterial peptide carrying an O-glycosylated substitution. It is the prototype of a new class of insect antibacterial peptides and this type of post-translational modification is observed in other molecules. (2) Drosomycin, isolated from *Drosophila*, is a cysteine-rich peptide with four intramolecular disulfide bridges. This molecule kills filamentous phytopathogenic and human pathogenic fungi. Drosomycin, which is the first inducible antifungal peptide isolated from insects has sequence and conformational similarities with plant defensins. (3) Thanatin, isolated from *Podisus maculiventris*, is particular by its activity spectrum which is directed against bacteria and fungi. Thanatin has one intramolecular disulfide bridge and sequence similarities with a class of frog skin antimicrobial peptides, the brevinin family. (4) In the scorpion, we have found a new cysteine-rich antimicrobial peptide, androctonin, which has no sequence similarities with other insect defense peptides but has a high degree of similarity with polyphemusins and tachyplesins, a family of antimicrobial peptides of *Limulus* (Arthropod, *Merostomae*). Androctonin has a broad activity spectrum. The data on the defense peptides in insects suggest that defensins have the largest distribution within this class. Similar substances were also found in scorpions and in molluscs. A phylogenetic tree for these molecules will be presented.

METCHNIKOWIN, A NOVEL ANTIMICROBIAL PROLINE-RICH PEPTIDE AND A NEW PATHWAY OF GENE EXPRESSION CONTROL ?

E.A. Levashina, S. Ohresser, P. Bulet, B. Lemaitre, J.-M. Reichhart, J.A. Hoffmann

Réponse Immunitaire et Développement chez les Insectes, UPR 9022 du CNRS, Institut de Biologie Moléculaire et Cellulaire, Strasbourg, France.

Drosophila melanogaster has become a pivotal model system for the study of the insect host defense, because of the exceptional advantages which this species offers in terms of molecular and classical genetics. We report here the isolation and characterization of metchnikowin, a novel 26-residue inducible proline-rich antibacterial peptide, which also exhibits antifungal activity. The gene, which maps in position 52A1-2 on the right arm of the second chromosome, is expressed in the fat body after immune challenge, following classical acute-phase kinetics.

Metchnikowin is the second immune inducible peptide with antifungal activity to be characterized so far in *Drosophila*. It has recently been shown that distinct pathways control antibacterial and antifungal gene expression (Lemaitre et al., in preparation). Since metchnikowin exhibits both antibacterial and antifungal activities, we address the question, whether the pathway leading to the induced expression of metchnikowin, is a combination of both, or whether it is a different, third pathway. For this, the transcriptional profiles of the metchnikowin gene were analysed in the backgrounds of mutant fly lines, which have been shown to affect the expression of dipterocin (antibacterial) and/or drosomycin (antifungal) genes. Preliminary results indicate, that the expression pattern of the metchnikowin gene is different from those of dipterocin and drosomycin. The structural and functional analysis of the promoter region of the metchnikowin gene will be presented and a possible pattern of regulation of the gene expression will be discussed.

07-012

DIVERSITY OF INSECT PEPTIDE ANTIBIOTICS WITH REFERENCE TO *HETEROPTERA*

S.I.Chernysh

Department of Entomology, St.Petersburg University, Russia

About 100 peptide antibiotics found to date in insects demonstrate great structural diversity of effector molecules involved in insect innate immunity. Reporting here findings of antibacterial and antifungal peptides in *Palomena prasina* and *Podisus maculiventris* (Pentatomidae) in comparison with other insects allow to analyse peculiarities of humoral immune response in *Heteroptera* and some evolutionary trends in insect immunity.

All investigated bugs produce in response to septic injury a battery of antibacterial peptides selective to Gram-positive or Gram-negative bacteria with the exception of *P.maculiventris* thanatin killing various bacteria and fungi. Cytotoxic to Gram-positive bacteria materials are insect defensins, highly conservative 3 disulfide bonds containing molecules characteristic to many insects and to noninsect arthropods. The peptides cytotoxic to Gram-negative bacteria are more variable. Some of them such as glycine-rich hemiptericin of *Pyrrhocoris apterus* or one-disulfide bond containing thanatin have been isolated from one species only. Pyrrhocoricin of *P.apterus* and metalnikowins of *P.prasina* and *P.maculiventris* are structurally related proline and arginine rich peptides. In contradistinction to glycosylated uniform pyrrhocoricin, nonglycosylated metalnikowins are represented by 4 or 5 isoforms. Phylogenetic reconstruction shows that metalnikowins ancestor gene probably amplified 34-45 million years ago, much before *Palomena* and *Podisus* species diverged.

The author is indebted to J.Hoffmann, F.Bulet, C.Hetru, S.Cociancich and P.Fehlbaum for the cooperation.

07-014

THE DNA SEQUENCE ENCODING THE ANTIBACTERIAL PEPTIDE FROM *ARTOGEIA RAPAE*

G.-S. Tae, K. Y. Jeong, and S. M. Yoe

Department of Biology, Dankook University, Cheonan, Korea

The partial DNA sequence, possibly encoding the cecropin-like antibacterial peptide, has been obtained from analysis of the DNA fragment being amplified by Reverse Transcriptase-PCR from the *Artogeia rapae* fat body challenged with *E. coli* K12. Three different kinds of the degenerate primers were designed on the basis of highly conserved DNA sequences of the known lepidopteran cecropin family: two of them are located on the preprosequence and the remaining is on the NH₂-terminal region of the structural gene.

The amino acid sequence deduced from the cDNA sequence shows 52-76% homologies to those of cecropins. Especially, highly conserved amino acid residues through the antibacterial peptides from moth are also well conserved in this sequence. It does not match exactly with any of the purified antibacterial peptides such as the hinnavin I and II, the antibacterial peptide purified from the *Artogeia rapae*, even if it shows higher amino acid homologies. The NH₂-terminal domain seems to be more conserved than the COOH-terminal domain which is believed to confer the spectrum of the antibacterial activities.

In order to obtain the complete cDNA sequence, the complementary analysis of cDNA library and marathon PCR technique is now being applied. Northern blot analysis will also show the expression patterns of this sequence in *Artogeia rapae*.

07-013

CAN LIFE-HISTORY DIFFERENCES EXPLAIN VARIATION IN ANTIBACTERIAL RESPONSES IN BEES (HYMENOPTERA: APOIDAE)?

Jane A. Rees

Department of Zoology, Oxford University, Oxford, UK.

Honeybees live in warm and resource-rich environments which favour parasite invasion. British honeybees (*A. m. ligustica*) have larger feral colonies and lower nest absconding rates than Kenyan honeybees (*A. m. scutellata*). They also overwinter with large food stores, whereas Kenyan honeybees forage all year. British honeybees may therefore need more effective defense from parasites and pathogens. Comparisons of haemolymph antibacterial responses using agar plate growth inhibition assays supported this hypothesis. Naive antibacterial activity did not differ between honeybee races. However, after parenteral bacterial challenge, the antibacterial response of British honeybees was greater and of longer duration than those of Kenyan honeybees. Factors other than group size will also effect selection on immune systems; provisional data on the antibacterial responses of three less social British bees (*Bombus pascuorum*, *Lasioglossum* spp., *Psithyrus vestalis*) do not neatly fit into the sociality-immunocompetence theory. A modified hypothesis suggests that advanced hygienic behaviours found only in honeybees may partly negate the effects of increased group size.

The antibacterial peptides responsible for this activity were isolated in collaboration with Dr. P. Bulet, Institut de Biologie Moléculaire et Cellulaire, Strasbourg, France. There was microsequence variation in the peptides of Kenyan and British honeybees. *B. pascuorum* produced the same categories of peptide, but interspecific sequence variation was greater than intraspecific variation. C-terminal amidation of one category of peptide, a bee defensin, was shown for this bumblebee species.

07-015

MOLECULAR CHARACTERIZATION OF CERATOTOXINS, SEX-SPECIFIC ANTIBACTERIAL PEPTIDES FROM THE MEDFLY *CERATITIS CAPITATA* (DIPTERA:TEPHRITIDAE)

M. Rosetto, A.G.O. Manetti, T. de Filippis, C.T. Baldari, L. Marri¹, D. Marchini and R. Dallai

Department of Evolutionary Biology, University of Siena, Via P.A. Mattioli 4, Siena, Italy - ¹ Department of Molecular Biology, Section of Microbiology, University of Siena, Via Laterina 8, Siena, Italy

The secretion of the female reproductive accessory glands of the medfly *Ceratitis capitata* has been shown to have an antibacterial activity. This property was ascribed to the presence of two cationic peptides (3kDa molecular mass) named ceratotoxins A and B, in addition to a lysozyme-like activity. The cDNA encoding ceratotoxin A has been isolated and the expression of this gene was analyzed. Ceratotoxin A is a sex-specific gene, related to sexual maturity in females, stimulated by mating and produced exclusively by the accessory glands. Since the juvenile hormone has a gonadotropic activity in the adult insect and morphological data show that the accessory gland development parallels that of the ovary, a possible interaction between the hormone and ceratotoxin expression has been hypothesized. This theory is supported by the effectiveness of the anti-juvenile hormone precocene II in suppressing ceratotoxin A gene expression. Another peptide having an antibacterial activity lower than that of ceratotoxin A has been purified from the gland secretion using a polyclonal antibody raised against ceratotoxin A, and its cDNA has been isolated. Based on the amino acid and nucleotide sequences it has been named ceratotoxin C.

Recently, two clones from a *Ceratitis capitata* genomic library hybridizing to a ceratotoxin cDNA probe have been isolated. The longer one, 26 kb, showed the presence of several ceratotoxin genes, revealing their clustered organization. The promoters of four ceratotoxin genes sequenced show some highly conserved motifs, suggesting the possibility of common regulatory elements for all ceratotoxin genes.

07-016

TRANSCRIPTIONAL REGULATION OF THE *DROSOPHILA* CECROPIN GENES

Y. Engström, G. Björklund, L. Kadalayil, U.-M. Petersen, E. Roos
Department of Molecular Biology, Stockholm University, S-106 91
Stockholm, Sweden. Phone: +46-8-16 41 66, Fax: +46-8-15 23 50,
e-mail: ylva@strix.molbio.su.se.

We are interested in the function of the *Drosophila* immune response and as a model system we are studying the regulation of the *Cecropin* (*Cec*) genes. To identify *cis*-acting elements responsible for the inducible and tissue-specific transcription of the *Cec* genes we constructed a set of *Cec-lacZ* fusion genes. Their expression are analyzed by transfection and transient expression in cell lines and *in vivo* after P-element mediated transformation. Three regulatory elements, "R1", "κB" and "GATA", were identified as being necessary for normal *Cec* gene expression. Disruption of either of the κB or the GATA motifs results in inactivation of the promoter. The Rel protein Dif binds specifically to the κB site and acts as a strong transcriptional activator of *Cec-lacZ* constructs in cotransfection assays. Site-directed mutagenesis of Dif revealed that a conserved arginine at position 94 in the Rel domain is essential for Dif's activity. The Rel protein Dorsal can also activate the *CecA1* promoter, but to a lesser extent than Dif. Simultaneous overexpression of Dif and Dorsal in cotransfection assays revealed that Dorsal possesses a dominant negative effect on Dif *trans*-activation. We have also identified another DNA-binding activity recognizing the "GATA" motif, a well-known *cis*-acting element in vertebrates. The GATA site is located just adjacent to the κB site and some data indicate that the κB- and GATA-binding activities physically interact.

07-018

EARLY RESPONSE GENES IN THE *DROSOPHILA* IMMUNE DEFENSE; A NOVEL NF-κB-LIKE TRANSCRIPTION FACTOR

M. Dushay, B. Åsling, D. Hultmark

Department of Developmental Biology, Stockholm University,
Stockholm, Sweden

In an effort to identify factors involved in the activation of immune responses, we use the PCR-based differential display technique to isolate genes which are induced by infection in *Drosophila*. Among induced genes, we find examples both of effector molecules, such as cecropin and attacin, and of regulatory molecules involved in the activation mechanism.

One induced gene, dubbed *Relish*, codes for a novel member of the Rel/NF-κB family of transcription factors, well-known activators of immune reactions in both mammals and insects. Similar to the mammalian NF-κB precursor p105, Relish includes a domain with six ankyrin repeats, related to the IκB class of NF-κB inhibitors. Transfection experiments show that Relish can activate transcription from a cecropin promoter, and this factor is likely to be an important regulator of the immune reaction. A specific *Relish* transcript is seen in early embryos, indicating that this gene, like *dorsal*, may also play a role in embryogenesis.

07-017

ADJACENT GATA AND κB-LIKE MOTIFS REGULATE THE INDUCTION OF IMMUNE GENES IN *DROSOPHILA*

Latha Kadalayil, Ulla-Maja Petersen and Ylva Engström
Department of Molecular Biology, Stockholm University, Stockholm

GATA motif is a well-known positive *cis*-regulatory element in vertebrates. Here we report the occurrence of such motifs in the promoters of a number of inducible insect immune genes and two mammalian acute phase response genes, IL6 and IL3. The GATA motifs in the proximal promoter region of these genes are located close to κB-like sites. The κB sites are positive *cis*-acting elements for the expression of *Cecropin A1* (*CecA1*). We present experimental evidence for the direct participation of the GATA motif in the expression of the *Drosophila CecA1* gene. A *Drosophila* blood cell line contains factors which bind specifically to the GATA motif of the *Cecropin A1* gene. These factors are likely to be members of the GATA family of transcriptional regulators. It is possible that, like in the case of insect immune genes, the GATA proteins may be involved in the mammalian IL6 and IL3 regulation as well. Thus, the previously proposed evolutionary relationship between the mammalian innate immunity and insect immunity via κB sites and Rel proteins may extend to include the participation of GATA elements as well. Antibodies against the *Drosophila* Rel protein, Dif, a known positive mediator of *CecA1* gene expression, recognises components of the GATA motif-specific complexes. This and the proximity of these two functionally important *cis*-acting elements in insects suggest an interaction between Dif and the GATA motif-specific factors in *Cec* gene regulation in *Drosophila*.

MULTIFACTORIAL CONTROL OF EXPRESSION OF ANTIBACTERIAL GENES IN *DROSOPHILA*.

C. Kappler, P. Georgel, E. Langley, I. Gross, J.M. Reichhart and J.A. Hoffmann.

Institut de Biologie Moléculaire et Cellulaire, UPR 9022 du CNRS,
15 rue René Descartes, 67084 Strasbourg cedex, FRANCE.

Insects respond to bacterial challenge by the rapid and transient synthesis of a battery of potent antimicrobial peptides. The analysis of the promoters of the genes encoding two of these molecules, diptericin and cecropin, revealed the presence of regulatory motifs homologous to *cis*-acting elements involved in the acute phase response in mammals (1). Among these motifs, decameric sequence elements similar to the binding sites for Nuclear Factor κB (NF-κB) have been shown to be mandatory for immune-induced transcription of both genes (2,3). However, the identity(ies) of the *trans*-acting protein(s) involved in this process remains unclear. We have investigated the transactivating capacities of the two *Drosophila* rel proteins dorsal and Dif (4,5) on reporter genes fused to either the diptericin or the cecropin κB-related motifs. We show by transfection experiments and DNA binding studies that these motifs are not functionally equivalent. Our results suggest that the diptericin and the cecropin genes are not regulated by the same activators or by the same combination of factors.

JAK KINASE SIGNAL TRANSDUCTION PATHWAYS REGULATE *DROSOPHILA* HEMATOPOIESIS.

C.R. Dearolf, H. Luo, and T. Parke

Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA, USA

In the fruit fly *Drosophila melanogaster*, blood cells are an important component of the host immune response. We are studying mutations in the *hopscotch* (*hop*) locus that disrupt hematopoiesis and cause leukemia-like defects, including the overproliferation and premature differentiation of hemocytes. The *hop* gene encodes a member of the Jak kinase family of non-receptor tyrosine kinases. Jak kinase proteins are known to play a vital role in the response of mammalian blood cells to cytokine stimulation.

We have used genetic and biochemical methods to identify other components of the Jak kinase regulatory pathways in *Drosophila*. We report on interactions of *hop* with other intracellular signaling molecules, including a fruit fly *raf* homolog. The regulatory role of these pathways in hematopoiesis and in the immune response will be described.

07-022

AN IMMUNE STIMULATED GENE EXPRESSED IN INSECT LARVAE ENCODES AN ALDOSE REDUCTASE-LIKE PROTEIN

A. Lundström, D.-W. Kang, G. Liu, and H. Steiner

Department of Microbiology, Stockholm University, Stockholm, Sweden

The immune state of insects is defined by a set of proteins that is absent in the naive state. To explore the immune system of *Trichoplusia ni* in more detail we have employed a PCR differential display technique to compare the mRNA population of untreated last instar larvae to that of immunized animals.

In the primary display, more than one hundred bands seemed induced upon bacterial challenge. When screening a cDNA library from immunized larvae with one of these amplified bands, we isolated a clone for an aldose reductase-like protein. The corresponding mRNA was found to be slightly up-regulated in developing last instar larvae. However, a bacterial infection strongly augments this response. This demonstrates the potential of the differential display PCR technique to find an immune regulated gene despite its background expression seen in larval development.

A comparison of the aldose reductase mRNA levels in different organs indicated that the fat body is the major place of synthesis.

The aldose reductase-like protein was over-produced using the baculovirus expression system. Two major bands of molecular weights 31 and 32 kDa were found. The product had aldose reductase enzyme activity and was affinity purified on Blue Sepharose.

The major function of aldose reductase in other systems is to produce osmo-protectants such as sorbitol or mannitol in response to stress situations. However, the concentrations of such sugar alcohols did not increase in response to immune stimulation. Work is now in progress to understand the function of the *T. ni* aldose reductase in insect immune induced stress.

07-021

IMMUNE SYSTEM GENES AND MUTATIONS CAUSING TUMOR FORMATION IN *DROSOPHILA*

D. A. Kimbrell, C. Wu, A. Rodriguez, Z. Zhou, J. Chen, A. Bernal
Department of Biology, University of Houston, Houston, Texas USA

We are using *Drosophila* as a model system for the analysis of immunity and tumor formation and have conducted two types of screens using enhancer detector strains to find genes related to these processes: (A) genes expressed in immune system tissues, i.e. hemocytes, lymph glands (the hematopoietic organ) and fat body (major site of antibacterial protein synthesis); (B) genes increased in expression by bacterial infection. Among the genes of types A and B, we hypothesized that a third type would be found: genes that when mutated have a melanotic tumor phenotype. 2,800 enhancer detector strains were screened for type A and 900 for type B, and 11 strains retained for further analysis. Complementation tests, cytological mapping of *P* elements, mobilization of *P* elements, and determination of time of lethality and mutant phenotype have identified six novel genes, *Dorothy*, *wizard*, *toto*, *viking*, *Thor* and *dappled*, and one previously identified gene, *Collagen IV*. All of the novel genes are associated with reporter gene expression in at least one immune system tissue. One is also associated with an increased level of expression upon bacterial infection. Mutations of two of the novel genes have a melanotic tumor phenotype. We are currently working on the molecular characterization of three of these genes, in particular *dappled* will be presented. Mutations of *dappled* show tumor formation associated with aberrant gut and fat body; one mutation is viable with 100% tumor formation and another is lethal with tumor formation in early larval development. The enhancer detector insertions in these strains are approximately 100 base pairs apart. Molecular characterization will help determine the recognition and response by the immune system when aberrant self tissue is present.

07-023

ANALYSIS OF ENHANCER TRAP LINES FOR THE STUDY OF *DROSOPHILA* HEMOCYTES.

M. Meister, A. Braun, J.A. Hoffmann

Institut de Biologie Moléculaire et Cellulaire, CNRS, 15 rue René Descartes, 67084 Strasbourg cedex, France.

The immune response of insects involves two distinct mechanisms: a humoral facet characterized by the synthesis in the fat body of various antimicrobial peptides, and a cellular response by the hemocytes, which is still poorly understood. Insect hemocytes have been investigated for some fifty years. The classifications that have been published to date are based on morphological and more rarely functional criteria. In *Drosophila*, several blood cell types have been described. In third instar larvae, the lymph glands constitute the major (perhaps unique) source of circulating hemocytes which can be classified into three cell types : (i) the crystal cells (5 - 10 % of the hemocytes) contain the components of the circulating prophenoloxidase cascade which participates in the defense-related melanisation processes ; (ii) the plasmatocytes which are small round cells that account for most of the blood cell population and are believed to contribute to the host defense of *Drosophila* (phagocytosis of bacteria, production of antimicrobial peptides) and (iii) lamellocytes which are characteristically flattened cells. In the larvae lamellocytes serve in the process of encapsulation. At the end of the larval instar the plasmatocytes differentiate into lamellocytes which predominate in the blood cell population of prepupae. This differentiation is under hormonal control.

We have screened ca. 1300 β -galactosidase enhancer trap lines for expression of the transgene in various subsets of larval hemocytes. This expression has been analysed in different mutant contexts known to affect the larval hemocytes. We describe a P-element mediated mutation on the second chromosome which results in the absence of circulating hemocytes in larvae, and in early pupal lethality. The incidence of this mutation on the immune response is analysed.

MOLECULAR APPROACHES TO ANOPHELES GAMBIAE IMMUNITY

A. Richman¹, C. Barillas-Mury¹, P. Bulet², C. Hetru², J. A. Hoffmann², F. C. Kafatos¹

¹European Molecular Biology Laboratory, Heidelberg, Germany - ²Institut de Biologie Moléculaire et Cellulaire, Strasbourg, France

Vector-mediated transmission of *Plasmodium* (the agent of malaria) requires successful growth and differentiation of the parasite within the physiological environment of a mosquito host. Various barriers to *Plasmodium* development have been documented in particular mosquito species and strains, which suggest that in some cases the immune system of the mosquito can limit vectorial capacity. Great progress has been made in understanding insect immune mechanisms, largely through biochemical and molecular studies focused upon a few model species. In the case of *Anopheles gambiae*, the principal vector of human malaria in Africa, molecular aspects of immunity are only now in the process of being elucidated. In initial experiments, *An. gambiae* homologues of genes implicated in mediating the insect immune response to microbial agents have been identified. The gene products are being analyzed for their utility as probes to monitor the mosquito response to infection by *Plasmodium* parasites.

We have cloned a gene encoding the *An. gambiae* homologue of insect defensin, an inducible antibacterial protein. Defensin RNA levels are elevated rapidly following bacterial infection challenge of larval and adult stage mosquitoes. A member of the rel-family of transcription factors has also been identified in *An. gambiae*. Rel-family members are implicated in the regulation of infection-inducible expression of a number of insect immune factor genes. The activities of defensin and the rel-factor are being analyzed during the course of mosquito infection by *Plasmodium* parasites.

Biochemical fractionation of extracts prepared from bacterially-challenged mosquitoes reveals numerous distinct, inducible antibacterial activities. The antibacterial proteins are being purified and sequenced, leading to the identification of the corresponding cDNAs (thus providing additional markers which may prove useful in analyzing the mosquito response to parasite infection).

To specifically address the mosquito immune response to *Plasmodium* infection challenge, the mRNA differential display technique is being used to identify *An. gambiae* genes that are transcriptionally activated as a consequence of ingestion of an infective blood meal. Results of these experiments will be discussed.

07-026

ANOPHELES STEPHENSI : INDUCIBLE ANTIBACTERIAL PEPTIDES AND GENETIC SELECTION ACCORDING TO ANTIBACTERIAL ACTIVITY.

W.Y.W.SULAIMAN, R. CHALK and P.J.HAM.

Centre for Applied Entomology and Parasitology,
Department of Biological Sciences,
Keele University,
Staffordshire ST5 5BG,
U.K.

Molecules are known to be induced in the haemolymph of insects by infection or injury and some of these have antiparasitic and bactericidal activity. In mosquitoes, although the outward manifestation of refractoriness to infection is melanization, the actual mediator of parasite death may involve these immune peptide(s). Some have been found in *Aedes aegypti*, and other vectors of parasitic infection.

The results of antibacterial zone assays show that the haemolymph of immunised *An. stephensi* contain substances with activity against gram-negative and gram-positive bacteria. Genetic selection based on the levels of anti gram-negative activity have resulted in the production of two mosquito lines; one that demonstrates low responding activity and one that demonstrated high responding activity against *E.coli* D31. Results from this selection experiment and the complete amino acid sequences of antibacterial peptide(s) from the selected lines of these mosquitoes are presented.

07-025

THE IMMUNE FACTOR GAMBIF1 IS A NOVEL REL-FAMILY MEMBER FROM THE HUMAN MALARIA VECTOR AN. GAMBIAE,

C. Barillas-Mury, A. Charlesworth², I. Gross³, A. Richman, J. Hoffmann³, F.C. Kafatos

European Molecular Biology Laboratory, Heidelberg, Germany - 2 European Institute of Oncology, Milan, Italy - 3 Institut de Biologie Moléculaire et Cellulaire, UPR 9022 du CNRS, Strasbourg Cedex, France

A novel rel-family member, Gambif1 (gambiae immune factor), from the human malaria vector *An. gambiae* has been cloned. It has the highest homology to *Drosophila* dorsal and Dif. Gambif1 mRNA is present at low levels in all developmental stages. Its protein is translocated to the nuclei of fat body cells in response to bacterial challenge. DNA binding activity to the *Drosophila* dipterin and cecropin, and the *An. gambiae* defensin kB-like sites is also induced in larval nuclear extracts following bacterial infection. Gambif1 has the ability to bind to kB-like sites. Co-transfection assays in mbn-2 cells show that Gambif can activate transcription by interacting with the *Drosophila* dipterin regulatory elements and that it is not functionally equivalent to dorsal. These molecular markers of activation of the immune system open the possibility to study the role of the mosquito defense reactions in determining their susceptibility/refractoriness to malaria infection.

Injection of non-pathogenic bacteria is known to induce an immune response in several insect orders. Using HPLC coupled to antimicrobial bioassays, we have characterised this response in 2 medically important Diptera. In the mosquitoes *Aedes aegypti* and *Anopheles stephensi*, immune haemolymph is active against both Gram positive and Gram negative microorganisms. *Ae. aegypti* possesses two insect defensin isoforms and an inducible haemolymph lysozyme which are active against Gram positives. In this species 2 types of anti-Gram negative activity are now described. The first consists of a family of at least 5 small peptides for which preliminary sequence data is presented. The remaining activity appears to be due to a single larger peptide, with different HPLC characteristics. The malaria vector *An. stephensi* possesses at least one defensin with 90% identity to the *Ae. aegypti* defensins, and at least one type of anti-Gram negative activity is also present in this species.

IMMUNE ACTIVATION OF *AEDES AEGYPTI* REDUCES THE ESTABLISHMENT AND DEVELOPMENT OF *BRUGIA MALAYI*.

C. Lowenberger¹, M. Ferdig¹, P. Bulet², J.A. Hoffmann², and B. M. Christensen¹.

¹Animal Health and Biomedical Sciences, Univ. of Wisconsin-Madison, 1655 Linden Drive, Madison WI, 53706, USA. ²Institut de Biologie Moléculaire et Cellulaire, UPR 9022 CNRS, 15 rue René Descartes, 67084 Strasbourg cédex, France.

Mosquitoes respond to bacterial challenge or cuticular injury by the rapid production of potent immune proteins. We have identified three insect defensins produced by the mosquito *Aedes aegypti* in response to bacterial challenge. We evaluated the effect of immune activation on the establishment and development of *Brugia malayi* ingested in a blood meal both in susceptible and refractory strains of *A. aegypti*. Immune activated mosquitoes had significantly reduced prevalences and mean intensities of infection than did naive controls when exposed to bloodmeals with low (105 mf/20µl blood) and medium (160 mf/20µl blood) microfilaremias. Northern analysis showed that all mosquitoes demonstrated rapid defensin transcriptional activity after immune activation but no strain of *A. aegypti* produced defensin transcripts after bloodfeeding on control or parasite-infected gerbils. The data suggest that inducible immune proteins of mosquitoes can reduce the prevalence and mean intensity of infection with ingested parasites, but these proteins are not expressed routinely after parasite ingestion and midgut penetration. Immune proteins such as defensins, however, represent potential candidates to genetically engineer mosquitoes resistant to filarial worms.

07-030

A MONOCLONAL ANTIBODY AGAINST A HEMOCYTE 180 kDa POLYPEPTIDE INVOLVED IN CELLULAR DEFENCE REACTIONS IN THE STICK INSECT *BACILLUS ROSSIUS* (Rossi) (Phasmatodea, Bacillidae).

G. Scapigliati, M. Pecci, A. Piermattei and M. Mazzini.

Dept. of Environmental Sciences, University of Tuscia, I-01100 Viterbo, Italy

The monoclonal antibody BrH1 has been obtained immunizing mice with paraformaldehyde-fixed *Bacillus rossi* hemocytes and screening hybridomas by immunofluorescence with hemocyte monolayers. The antibody stains mainly granule-containing hemocytes in *in vitro* cultured cells, and cells having an irregular morphology in *in situ* transversal cryosections of adult insects.

BrH1 recognizes in western blotting analysis a 180 kDa antigen present in hemocyte lysates but absent from fat body lysates and from cell-free haemolymph. This antigen appears to be involved in cellular defence reactions against experimental *in vivo* challenge with killed yeast cells, since in immunofluorescence analysis of cryosections, a strong positivity has been observed around and between yeast cells after 18 hours of incubation.

The antigen recognised by BrH1 appears very likely contained in secretion granules released *in vivo* by stick insect hemocytes during defence reactions against microbial infection.

07-029

DEMONSTRATION OF AN INDUCIBLE DEFENSIN LIKE IMMUNE PEPTIDE IN THE HAEMOLYMPH OF *SIMULIUM DAMNOSUM* S.L. (DIPTERA:SIMULIIDAE) S.L. Kläger, H.E. Hagen, D.V. Barrault, D. Hultmark¹, P.J. Ham

Centre for Applied Entomology and Parasitology, Department of Biological Sciences, Keele University, Staffordshire, UK - ¹ Department of Developmental Biology, Stockholm University, Stockholm, Sweden.

Infections of *S.damnus* s.l. with bacteria or *Onchocerca* microfilariae lead to the induction of two peptides, visible on SDS-Tricine- polyacrylamide gels as a doublet of around 4.5 - 5 kDa. Growth inhibition zone assays and modified overlay assays revealed that at least one of these two peptides has a strong anti-gram positive activity. Due to the poor resolution of the overlay gels, the activity could not be allocated to one peptide of the doublet. As in other insects peptides of that size with antigram positive activity have been shown to belong to the group of insect defensins, we used defensin homology based generic primers in a Differential Display Reverse Transcription PCR. Several products are in the process of being sequenced, sharing partial sequence homology with other insect defensins.

07-031

APPLICATION OF MONOCLONAL ANTIBODIES TO STUDY INSECT HEMOCYTE FUNCTIONS

T. Trenczek,

Institute of Plant Sciences, Applied Entomology, ETH-Zurich, Clausiusstr. 25, CH-8092 Zurich, Switzerland

Insects respond to infections and parasitization with cellular and humoral defence mechanisms. Hemocytes respond to pathogens through phagocytosis, nodule formation, and encapsulation. They clearly distinguish self from non-self, thus play an important role in triggering immune responses in insects.

Several hemocyte types can be identified by light and electron microscopy. However, it is often difficult to identify hemocyte types with certainty because their morphology can vary depending on the experimental situation. This is especially true for *in vitro* experiments in which hemocytes have not been activated or did not have time to adhere and spread, therefore they can not be distinguished. In order to overcome these problems several monoclonal antibodies (mabs) have been developed against hemocytes of a few species.

This presentation will give an overview of studies in which mabs against hemocytes of *H. cecropia* and *M. sexta* have been used to identify distinct hemocyte types. Furthermore, it will be shown how mabs can be used to identify hemocyte changes during the development of *H. cecropia* that can not be detected morphologically. Also first results of experiments in which mabs have been used to interfere with hemocyte behaviour and functions (e.g. encapsulation) will be presented.

This work was partially done in collaboration with M. Kanost (Kansas State University, USA), C. Wiegand (Free University Berlin, BRD), and E. Willott (University of Arizona, USA).

MOSQUITO CELL LINES BIND ANTIBODIES MADE AGAINST *MANDUCA SEXTA* HEMOCYTES

E. Willott

Center for Insect Science, Arizona Research Labs, University of Arizona, Tucson, AZ, USA

In vitro work on insect hemocytes is feasible for large insects, such as the caterpillar *Manduca sexta*. Studying smaller insects, such as the mosquito, poses more problems. For some purposes, the cell lines established from these insects may be useful. But how hemocyte-like are the cell lines? Some monoclonal antibodies made against *M. sexta* hemocytes crossreact with mosquito, *Aedes aegypti* and *Anopheles gambiae*, hemocytes. They also bind to cells of several different mosquito cell lines.

07-033

IDENTIFICATION OF A HEMOCYTE MEMBRANE PROTEIN OF THE SILKWORM, *BOMBYX MORI*, WHICH SPECIFICALLY BINDS TO BACTERIAL LIPOPOLYSACCHARIDE

J. XU, M. YAMAKAWA

Laboratory of Biological Defense, National Institute of Sericultural and Entomological Science, Owashi Tsukuba, Japan

An *in vitro* system with isolated hemocytes of the silkworm, *Bombyx mori*, was developed to examine the induction mechanism of insect antibacterial proteins by bacterial lipopolysaccharide. The gene expression of *B. mori* cecropin B was triggered by LPS in this system. To identify LPS-binding site(s) of the hemocytes, the [¹²⁵I]LPS binding assay to the hemocytes was performed *in vitro*. The amount of [¹²⁵I]LPS bound to hemocytes increased proportionately with the increase of incubation time and LPS dose. The binding was strongly inhibited by excess unlabeled LPS or lipid A, indicating that the binding of [¹²⁵I]LPS to hemocytes contains a highly specific reaction. Moreover, the specific binding could not be detected with Bm-N4 cells in which cecropin B gene expression was not induced by LPS, suggesting that the LPS binding is specific for LPS responsive cells. The LPS binding was fully sensitive to the proteinase K treatment of intact hemocytes, suggesting that a protein(s) located on the surface of hemocytes is involved in the LPS binding. Fluorescein isothiocyanate conjugated-LPS binding assay demonstrated that this compound mainly binds to granular cells rather than other hemocytes under our assay conditions. Affinity-labeling with photoreactive-LPS allowed the identification of a 11 kDa LPS-binding protein in hemocytes, which might relate to the specific membrane receptor for LPS.

07-034

HEMOCYTE-MEDIATED CLEARANCE OF LIPOPOLYSACCHARIDE IN INSECTS: PROTEIN TYROSINE PHOSPHORYLATION REQUIREMENT

V.J. Marmaras, N.D. Charalambidis, C.G. Zervas, M. Lampropoulou, P.G. Katsoris and L.C. Foukas

Department of Biology, University of Patras, Patras, Greece

The response of *Ceratitis capitata* hemocytes to lipopolysaccharide (LPS) involves the induction of intracellular protein tyrosine phosphorylation and, hence, the release of biologically active molecules, including protein p47 and phenoloxidase activators. The effector protein p47, one of the two dominant hemocyte proteins of developing medfly, could not be normally traced in plasma. However, it is present on the cell surface, recognises and attaches to *E. coli* cells and it binds covalently tyrosine derivatives generated by the action of phenoloxidase.

The effector protein p47, activated phenoloxidase (either cell-associated or cell-free) and tyrosine, constitute a system responsible for the clearance of invaders from the hemocoel of medfly. According to our data, LPS (either cell-associated or cell-free) recognises and crosslinks membrane bound p47 via the intermediacy of tyrosine derivatives of eumelanin metabolic pathways generated by the action of phenoloxidase, as is the case for cuticular protein-chitin crosslinks during sclerotization.

This covalent association of LPS at the cell surface, immobilizes bacteria and evidently this is an initial step for their internalisation as judged by the resistance of LPS binding to dissociation by proteinase K. The novel aspect of our results appears to be the intracellular signaling pathways required for LPS internalisation.

07-035

INFECTION OF LEPIDOPTERAN LARVAE WITH A SMALL RNA VIRUS INDUCES MASSIVE SHEDDING OF MIDGUT CELLS.

K. H. J. Gordon, E. M. Brooks, A. L. Bawden, S. J. Dorrian and T. N. Hanzlik

CSIRO Division of Entomology, Canberra, ACT, Australia.

We are exploring how the midgut of lepidopteran larvae responds to infection by small RNA viruses. The differentiated columnar and goblet cells forming the single layer midgut tube are produced by division of regenerative cells located in the surrounding basal membrane. During larval growth, the columnar and goblet cells increase significantly both in size and in number. *Helicoverpa armigera* stunt tetravirus (HaSV) is highly specific for the midgut and is able to infect all three cell types. The virus displays pathogenicity only to the first three larval instars; in contrast, fourth instar larvae appear to recover from infection with proportionally higher doses. This is an ideal system to study the insect cellular response to virus infection *in vivo*, as no humoral response is likely.

Immunohistochemical studies at the electron, light and confocal microscope levels on midgut pathology in infected first instar heliothis larvae, along with molecular techniques, show that HaSV rapidly induces a massive increase in shedding of rejected midgut cells above the level of sloughing normally found in healthy larvae. This increased shedding exceeds the ability of regenerative cells to maintain a functional midgut, resulting in irreversible degeneration of the midgut. We are currently investigating the roles of cell-shedding and other factors such as gut cell number and structure in determining the sensitivity of neonates and the resistance of larger larvae to HaSV infection. Further work asks whether HaSV-induced apoptosis underlies cell-shedding.

07-036

BEHAVIOUR AND CYTOSKELETON ALTERATIONS OF PLASMATOCYTES FROM *GALLERIA MELLONELLA* CAUSED BY THE ENTOMOPATHOGENIC FUNGUS *METARHIZIUM ANISOPLIAE* AND ITS TOXINS

A. Vilcinskas¹, V. Matha², P. Götz¹

1 Institut für Zoologie der Freien Universität Berlin, Germany
2 Galena Co., Research Unit, Czeske Budejovice, Czech Republic

The entomogenous fungus *Metarhizium anisopliae* is known to release destruxins and cytochalasin. These secondary metabolites have been examined for their potential as pest control agents due to their toxic effects on insects. Entomogenous fungi may produce these toxins to kill the host or to incapacitate its immune system. With the aim to evaluate their function during mycosis we studied their influence on isolated plasmatocytes, which represent the main phagocytic cell type and participate in the encapsulation process within the hemolymph of *Galleria mellonella*. Attachment, filopodia formation, phagocytic activity and cytoskeleton formation of isolated plasmatocytes was examined under presence of destruxin or cytochalasin and in comparison with untreated plasmatocytes and plasmatocytes obtained from *Metarhizium anisopliae* infected larvae. Dissolved destruxin or cytochalasin in sublethal concentrations caused characteristic morphological and cytoskeleton alterations and suppressed attachment, filopodia formation and phagocytic activity of plasmatocytes in monolayers. Plasmatocytes isolated from diseased larvae exhibited similar effects concerning attachment, spreading and cytoskeleton formation. The corresponding effects on cell mobility and cytoskeleton formation in plasmatocytes *in vitro* and in plasmatocytes from infected larvae support the conclusion that entomopathogenic fungi release these toxins to interfere with cellular immune reactions of their hosts.

07-038

NEWLY DETECTED IMMUNE STIMULATING MOLECULES OF *GALLERIA MELLONELLA* (LEPIDOPTERA).

A. Wiesner, D. Wittwer, S. Losen, P. Kopáček¹, C. Weise², P. Götz
Institute of Zoology, Free University, Berlin, Germany - 1 Institute of Entomology, Czech Academy of Sciences, České Budejovice, Czech Republik - 2 Institute of Biochemistry, Free University, Berlin, Germany

In vivo and *in vitro* transfer studies were conducted to detect immune stimulating molecules in cell free larval haemolymph and in cell culture supernatants of phagocytically active haemocytes. Molecules derived from these sources were assayed for their ability to activate the antibacterial humoral response *in vivo* as well as the phagocytic activity of isolated haemocytes *in vitro*. Two activating factors could be characterized in more detail: Apolipophorin III (ApoLp-III) from larval haemolymph and a prostaglandin-like molecule released by phagocytosing haemocytes *in vitro*. ApoLp-III was revealed to be a heat stable protein with a molecular mass of 18077 Da. The UV-spectrum and the partially analyzed amino acid sequence data indicate that apoLp-III from *Galleria mellonella* and *Manduca sexta* are closely related. The prostaglandin-like factor is a small (< 500 Da), heat sensitive and hydrophobic molecule. The isolation procedures for both molecules, detailed data about their biological activities, and first results about their putative mode of action will be presented. The unexpected role of apolipophorin III as an immune activator and the central role of haemocytes in delivering immune regulating molecules will be discussed.

07-037

IDENTIFICATION OF A HEMOCYTE PROTEIN INVOLVED IN ENCAPSULATION OF FOREIGN MATERIAL IN THE TOBACCO HORNWORM, *Manduca sexta*.
C. Wiegand¹, J.P. Gillespie², Y. Wang², E. Willott³, T. Trenczek⁴ and M.R. Kanost².

¹ Institute of Zoology, Free University Berlin, Koenigin-Luise Strasse 3, Berlin, Germany, ²Dept. Biochemistry, Kansas State University, Manhattan, KS, ³Center for Insect Science, ARL, University of Arizona, Tucson, AZ, ⁴Institute of Zoology, Justus-Liebig University Giessen, Stephanstrasse 24, Giessen, Germany.

The biochemical events leading up to and during hemocytic encapsulation are poorly understood. We have initiated an investigation into the molecular basis of encapsulation and cell adhesion. Previously, we had prepared a panel of monoclonal antibodies that recognize hemocytes from *M. sexta* larvae. These antibodies have a wide range of hemocyte labeling characteristics. We have found one antibody, MS13, a plasmatocyte-specific membrane marker, interfered with the ability of the plasmatocytes to spread on glass slides. Also, pre-incubation of hemocytes with MS13 decreased the amount of latex beads encapsulated *in vitro*. We present information regarding the target protein for MS13 (termed HC13). This protein has been identified as an integral membrane protein with a molecular weight of 90-100 kDa. We also present data to show which types of cell are involved in the encapsulation process. This information is discussed in context with published results.

07-039

THE ROLE OF BDL1, AN ENDOGENOUS MANNOSE-SPECIFIC LECTIN, ON THE PHAGOCYTOSIS OF FOREIGN PARTICLES BY HAEMOCYTES OF THE COCKROACH, *BLABERUS DISCOIDALIS*.

R. Wilson, N.A. Ratcliffe
Biomedical and Physiological Research Group, School of Biological Sciences, University of Wales Swansea, Swansea. SA2 8PP, Wales, U.K.

BDL1, a mannose specific lectin isolated from the serum of *Blaberus discoidalis*, has previously been shown to activate the prophenoloxidase system. In this present study, the phagocytosis of foreign particles was examined, with a view to determining if an enhanced phagocytic rate in the presence of BDL1 was due to BDL1 activating the prophenoloxidase cascade or acting independently as an opsonin. In the presence of BDL1, the rate of phagocytosis, of some microorganisms is significantly increased above levels observed when prophenoloxidase is activated by laminarin alone. The role of BDL1 in this activation was determined using specific monoclonal antibodies to inhibit BDL1, and serine protease inhibitors to prevent the activation of the prophenoloxidase cascade.

07-040

SELECTION OF *Aedes aegypti* LINES HAVING QUANTITATIVE DIFFERENCES IN IMMUNE PEPTIDE ACTIVITY, AND THEIR ASSOCIATION WITH FILARIAL SUSCEPTIBILITY

P. J. Ham, H. Yang

Centre for Applied Entomology and Parasitology, Keele University, Staffordshire, United Kingdom

Data will be presented describing the phenotypic selection of two segregated lines of *Aedes aegypti* using the HUMORAL antibacterial immune response to bacteria inoculation as the selection criteria. The two lines, currently at the F¹⁰ generation, showed early differences through maternal selection. Responses against both *E. coli* and *M. luteus* were measured and other characteristics such as responses in males and the resulting susceptibility levels of females to *Brugia* infection have been determined. The latter show a clear association with the phenotypes used to generate these novel lines indicating a causal relationship between antibiotic activity and parasite development.

07-041

THE EFFECT OF HEMOLYMPH PLASMA ON THE HEMOCYTE BEHAVIOUR AND ITS POSSIBLE ROLE IN THE INITIAL IMMUNE RESPONSE OF INSECTS.

H. Lanz, S. Dorn and T. Trenczek.

Department of Applied Entomology, ETH-Centrum, Switzerland.

The activation of immune response still has a number of unresolved problems in arthropods. The sequence of biochemical events operative after microbial invasion or wounding and the subsequent immune reaction is not fully understood. It is likely that humoral factors influence hemocyte behaviour. We have found that plasma induced aggregation, spreading, and the formation of cellular networks in hemocytes from *Manduca sexta* and *Pieris brassicae* *in vitro*. Plasma from both species was ultrafractionated and the different fractions were tested. In *P. brassicae* the aggregation activity was observed in the fraction of 30-100 kDa and the spreading and the formation of cellular network was found in the fraction of 3-10 kDa. These factors were deactivated by heating (100 °C, 10 min) and by proteolytic enzymes. The spreading and network activity (3-10 kDa) was also deactivated after lipase treatment, suggesting that these factors are of proteic or lipoproteic nature. For *M. sexta* we found all activities expressed in a plasma fraction of less than 3 kDa. The activating factor (AF) resisted denaturing treatments and proteolytic enzymes. Hemocytes entrapped rat erythrocytes (RE) in large nodules in presence of the AF from *M. sexta* or the 3-10 kDa fraction from *P. brassicae*. These results suggest that caterpillar hemolymph contains necessary factors responsible of the hemocyte behaviour and activation *in vitro*. Current research in our laboratory is focused on the purification of these factors and their molecular characterisation.

07-042

ANTIPARASITIC AND ANTIMICROBIAL ACTIVITY IN INSECTS OF MEDICAL IMPORTANCE

Smithies, B.M., Chalk, R¹., Ham P.J.² and Townson H.
Department of Medical Entomology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, U.K. - 1
Department of Biological Sciences, Queens University, Belfast, U.K. - 2
Centre for Applied Entomology and Parasitology, Department of Biological Sciences, Keele University, Staffs. U.K.

Insects produce antibacterial factors in response to bacterial infection. Study of the humoral immune responses of *Simulium equinum* and *Aedes aegypti* has shown that both species synthesize anti-bacterial and anti-parasitic substances. Apidaecins, lysozyme and defensins have been isolated from *Aedes aegypti*. Lysozyme and a defensin-like peptide have been isolated from *Simulium equinum*. Results of the isolation of anti-bacterial factors and of the *in vitro* activity of *Aedes aegypti* defensin against eukaryotic and prokaryotic organisms will be presented.

07-043

PEPTIDOGLYCAN AS A SIGNAL MOLECULE FOR INDUCTION OF ANTIBACTERIAL PROTEINS IN THE SILKWORM, *BOMBYX MORI*

I. Morishima, M. Iketani, Y. Yamano
Laboratory of Metabolic Biochemistry, Faculty of Agriculture, Tottori University, Tottori, JAPAN.

Bacterial cell wall components such as peptidoglycan (PG) and lipopolysaccharide (LPS) are known to be effective elicitors for the induction of antibacterial proteins in insects. We have utilized the silkworm as a model for characterizing the induction mechanisms of antibacterial proteins. Currently, we have shown that the silkworm recognizes PG fragments of some definite structure as a signal molecule and transduces the signal to the genome, which then introducing the simultaneous synthesis of a series of antibacterial proteins such as cecropin and lysozyme in fat body. The minimum structure of PG required for the induction of antibacterial proteins was elucidated by injecting the silkworm larvae with PG fragments having structurally different peptides or different sugar chain length with or without cross-linking prepared from various species of Gram-positive bacteria. The PG fragments would be recognized by putative PG-binding protein on the fat body cells. We are also characterizing the nature of signal transduction after the recognition of PG by testing the effects of various inhibitors on the induction of cecropin and lysozyme mRNAs in cultured fat body.

07-045

ASABF, a cysteine-rich antibacterial protein isolated from the nematode *Ascaris suum*: A comparison with insect/arthropod defensins.

Y. Kato and S. Komatsu*
Department of Insect Physiology and Behavior, National Institute of Sericultural and Entomological Science, Tsukuba, Ibaraki 305, Japan, and
*Department of Molecular Biology, National Institute of Agrobiological Resources, Tsukuba, Ibaraki 305, Japan

Previously, we reported that at least three humoral defense activities (antibacterial, bacteriolytic, and agglutinating) were detected in the body fluid of the parasitic nematode *Ascaris suum*. The substantial nature of these activities was suggested to be proteins/peptides, because all of them were lost by trypsin digestion. One of them, ASABF (*A**s**c**a**r**i**s* *s**u**m* *a**n**t**i**b**a**c**t**e**r**i**a**l* *f**a**c**t**o**r*) is a heat-stable antibacterial protein with molecular mass of 7 kDa. Recently, we purified ASABF, and its amino acid sequence was determined. Eight Cys residues which might contribute to intramolecular disulfide bonds were found in this sequence. MPsrch data base searches revealed weak sequence identity between ASABF and insect/arthropod defensins (IADs), the antibacterial proteins which contain 6 Cys residues. Jumbling test supported that this similarity was significant. All of them were positively charged proteins. In addition, Gram-positive bacteria were much more sensitive to ASABF (IC₅₀=0.6 µg/ml, against *Staphylococcus aureus*) than Gram-negative bacteria (IC₅₀=50 µg/ml, against *Escherichia coli*), and this antibacterial spectrum is similar to IADs. However, ASABF consisted of over 60 residues, whereas IADs consisted of only 30-40 residues. The positions of Cys residues in the sequence of IADs were highly conserved, and they are essential to the antibacterial activity. In contrast, an additional Cys of ASABF was found at the internal position of conserved array of Cys residues. ASABF, therefore, is not a typical IAD, although ASABF might be evolutionally related to IADs.

07-044

PARASITISM BY *COTESIA GLOMERATA* (L.) INDUCES CHANGES IN HEMOLYMPH PROTEINS OF THE HOST *PIERIS BRASSICAE* (L.)

K. Ockroy, T. Trenczek, S. Dorn
Institute of Plant Sciences, Applied Entomology, ETH Zurich, Clausiusstrasse 25, CH-8092 Zurich, Switzerland

The cabbage moth *Pieris brassicae* is naturally parasitized by the braconid wasp *Cotesia glomerata*. Parasitism by *Cotesia glomerata* induces multiple changes in the physiology of *Pieris brassicae*. These changes mainly affect the development and the endogenous defence system of the host insect.

After parasitization changes in the hemolymph proteins of the host were found. Analysis of the hemolymph proteins with gelelectrophoresis showed "parasitism specific" polypeptides. One of these proteins appeared in the hemolymph two days post-parasitization while the other two proteins appeared a few days before the parasitoid larva emerged. The relative molecular weights of these parasitization induced proteins are around 38'000, 42'000 and 128'000 respectively. In several parasitoid-host systems "parasitism-induced" proteins have been identified. These become detectable in the host at varying times after parasitization. Whether these proteins play a role in the suppression of the host immune system or in the regulation of the host physiology is in most cases still unknown.

07-046

SCREENING FOR IMMUNE RELATED GENES BY DIFFERENTIAL DISPLAY

S. Ekengren, Y. Tryselius¹, M. Dushay, M. Hedengren and D. Hultmark
Dept. of Developmental Biology and -1 Dept. of Molecular Biology, Stockholm University, Stockholm, Sweden

We are performing a thorough analysis of the insect immune machinery, using *Drosophila melanogaster* as a model system. This is done by a technique of differential screening, the differential display reverse transcription PCR (DDRT-PCR), comparing normal flies to flies induced with bacteria. So far we have confirmed differential expression for eleven PCR-fragments isolated in an initial screen. Two of the fragments turned out to encode immune-related proteins of already known function. We are isolating cDNA clones for the rest of the fragments. One of the isolated clones encodes a protein consisting of 126 aa, but sequence analysis suggests that it might be further processed into a smaller peptide. The rate of induction, amino acid composition, localization and expression pattern of this protein show several unique and very interesting features. The immune function of this protein are presently under investigation. Two different sets of genes are expected to be activated and therefore found in this screen. Genes encoding effector molecules and genes that code for molecules involved in the induction process such as receptors, messenger molecules, transcription factors etc. Several of the fragments isolated so far show a very interesting and promising pattern on northern blots.

07-047

ANTIBACTERIAL PEPTIDES FROM *SPODOPTERA LITURA*Sung Moon Yoe, Chung Sik Choi¹, Hak Ryul Kim¹

Department of Biology, Dankook University, Cheonan, Korea,

¹Department of Biology, Korea University, Seoul, Korea

Sixth instar larvae of *Spodoptera litura* were found to contain inducible antibacterial activity in their haemolymph. This immune reaction was induced by primary infection with viable 10^6 log phase of *E. coli* K-12 into the thorax. These proteins were separated and two of them were purified to homogeneity by ion-exchange chromatography, gel filtration and reverse phase FPLC. The purified proteins have strong antibacterial activity against gram negative and gram positive bacteria, and these proteins were named as spodopsin Ia and Ib, respectively. The sequences of spodopsins are confirmed by three methods, such as amino acid composition analysis, Edman degradation and electrospray mass spectrometry. Both spodopsins consist of 35 amino acid residues and molecular weights are approximately 4 kDa. We will discuss these peptides.

07-049

SECRETION OF SANDFLY MIDGUT LECTIN IS STIMULATED BY PROTEINS IN THE MEAL

P. Volf, L. Palánová

Department of Parasitology, Faculty of Sciences, Charles University, Prague, Czech Republic

Midgut lectin activities (LA) of *Phlebotomus duboscqi* and *Lutzomyia longipalpis* (Diptera: Psychodidae) were elevated after bloodfeeding to reach peak levels two or three days later. In unfed flies the lectin was associated mainly with microvillar surface, in fed ones it was secreted into midgut content. In both unfed and bloodfed flies the sugar binding specificities of LA were similar and anti-lectin antibodies recognized the same protein band in immunoblotting.

Different protein solutions were fed to female flies through membranes. Positive correlation was found between the extend of lectin secretion and the protein concentration in the meal. Stimulatory effect on gut lectin secretion had all protein solutions used. Bovine serum albumin and hemoglobin were equally effective as blood derivatives of the same protein content. Possibility that sandfly midgut LA and proteases might form a functional complex which participates on bloodmeal digestion and interaction with transmitted pathogens is discussed.

07-048

DIFFERENTIATION OF HEMOCYTES IN HEMOPOIETIC ORGAN OF *BOMBYX MORI* L.

Sung-Sik Han, Min-Ho Lee

Department of Agricultural Biology, Korea University, Seoul 136-701, Korea

Bombyx mori L. larva was investigated with a transmission electron microscopy to determine hemocytic differentiation in the hemopoietic organ located in thorax. Three or four types of stem cells in compact islets of the organ were observed. Immature hemocytes in loose islets of the organ were more differentiated and developed than in compact islets. Prohemocyte, plasmatocyte, granulocyte and oenocytoid were observed in loose islets. Each type of hemocyte was differentiated from each type of stem cell. However, none of spherulocyte was observed. Each type of hemocytes matured in loose islets were discharged into hemolymph by the tearing of acellular membrane covering the islets. The more detailed pathway of differentiation of hemocytes in *B. mori* was represented by the this investigation.

07-050

POSSIBLE ROLE OF A PURIFIED LECTIN FROM HAEMOLYMPH OF THE DESERT LOCUST SCHISTOCERCA GREGARIA MECHANISMS AGAINST THE PROTOZON MALAMOEBA LOCUSTA.

D. Dakouo (1), S. Essuman (2), M. Brehelin (3), S.K. Raina (2)

1. Institut d'études et de Recherches Agricoles (INERA) Station de Farako-Bâ, Bobo-Dioulasso, Burkina Faso.

2. International Centre of Insect Physiology and Ecology (ICIPE) Nairobi, Kenya. 3. - Laboratoire de Pathologie Comparée, Université de Montpellier II, France.

Haemolymph from the desert locust showed agglutination activity for mammalian erythrocytes and protozoa. A purified lectin was isolated from plasma by affinity chromatography. Analysis of the purified lectin by SDS-PAGE gave a single band at 80 KD while on native PAGE, a single band at 650 KD. Galactosides with an & D configuration were found to inhibit agglutination activity. This lectin enhanced *Malamoeba locustae* cysts fixation on locust hemocytes. Immunoblot analysis using antiserum raised against the purified lectin indicated that lectins from *S. gregaria* and *Locusta migratoria* share common immunological characteristics. Elisa tests used to assess the level of lectin gave higher titres in infected locusts as compared to controls. Phagocytosis appeared to be a major factor in the clearance of *M. locustae* from locust haemolymph. The highest level was reached 6 hours post inoculation and clearance of cysts from live insects was completed after 48 hours. The role of lectin in phagocytosis process and locust defense mechanisms, and the use of lectin inhibitors in locust control management are discussed.

Key words : Desert locust, *Schistocerca gregaria*, *Malamoeba locustae*, lectin, purification, immunoblot, Elisa, agglutination, phagocytosis.

07-051

TRANSFERRING ANTIBACTERIAL PEPTIDE GENE FROM CHINESE OAK SILKWORM INTO YEAST AND IDENTIFICATION OF ITS EXPRESSED PRODUCTS

Ma Li-jin Zhuang Chu-xiong Huang Zi-ran
South China Agricultural University, Guangzhou 510642, P. R. China

A synthetic antibacterial peptide gene (APG) from Chinese oak silk worm, *Antheraea pernyi* was recombined with a shuttle plasmid pCLWA2 containing an alpha-factor promotor and transferred into yeast AB103. The cells of yeast grew well under 28-30°C, pH 5.0 in YEPD medium. The expressed products were identified by electrophoresis with detection of antibacterial activity. The expressed peptide has a molecular weight of 4000 daltons. The yield of products reached a level of 1.14mg/L YEPD and its activity unit is about 0.216U.

07-053

PURIFICATION OF A HUMAN ALTERNATE COMPLEMENT PATHWAY INHIBITING PROTEIN FROM THE HEMOLYMPH OF THE SILKWORM LARVAE, *Bombyx mori* Y.Sekijima, Y.Fujikura, T.Hiyama¹, T.Maenaka¹ and A.Uda¹

Department of Immunology, Saitama College of Health, Urawa 338, Japan - ¹ Department of Biochemistry and Molecular Biology, Faculty of Science, Saitama University, Urawa 338, Japan

The hemolymph of the silkworm larvae has been shown to possess factor capable of inhibiting human alternate complement pathway. To elucidate the property, a human alternate complement pathway inhibiting protein(HALP-SHIS)was purified from the hemolymph of the silkworm larvae.The activity of HALP-SHIS was determined by ACH50 to rabbit erythrocytes and a hemolytic agar plate assay, which has been developed by us. The supernatant of 30%(NH₄)₂SO₄ saturation was applied on a DEAE-Toyopearl 650M (TOSOH) column equilibrated with 100 mM phosphate buffer(pH 7.2). Bounded HALP-SHIS was eluted in the range of 200-250 mM NaCl. The active fractions of HALP-SHIS were pooled and then applied on a Butyl-Toyopearl 650C,hydrophobic adsorbent(TOSOH) column equilibrated with 50 mM phosphate buffer(pH 7.2) and 750 mM ammonium sulfate. HALP-SHIS was eluted in the range of 150-0 mM ammonium sulfate. For further purification, HALP-SHIS was passed through on a hydroxylapatite(PENTAX)column equilibrated with 100 mM phosphate buffer(pH 7.2). Purified HALP-SHIS was migrated in the SDS-PAGE to two positions corresponding to molecular masses of 37 kD and 39 kD. On western blot analysis with a polyclonal antibody against crude HALP-SHIS,the both bands were blotted.Determining the NH₂-terminal amino acid sequence of HALP-SHIS is being carried after SDS-PAGE and transfer onto PVDF membrane. We will be discussed a possible mechanism for complement and whether HALP-SHIS protein is similar to complement of vertebrates.

SUBTRACTIVE cDNA CLONING OF *HYPHANTRIA CUNEA* (LEPIDOPTERA: ARCTIIDAE) LARVAL GENES INDUCED BY INJECTION OF *ESCHERICHIA COLI*

H.Y.Park, S.S.Park, S.W.Shin
Insect Resources Laboratory, Korea Research Institute of Bioscience & Biotechnology, KIST, Taejon, Korea

cDNA library, induced by injection of *E. coli* to the larvae of the fall webworm, *Hyphantria cunea*, was subtracted with uninduced mRNA of the larvae. The total RNA was isolated from the immunized larvae and cDNA library using Uni-ZAP XR vector was constructed. This library was infected to the host cells (XL1-Blue MRF') with helper phages (VCSM13), and single strand DNA phages were excised by in vivo excision protocol. From these phages, single strand DNA (pBluescript SK(-) phagemid) was isolated and twice subtracted with 10-fold biotin-labelled mRNA from the unimmunized larvae. By PCR reaction with subtracted single strand DNA as template, the cDNA insert was amplified and cloned to the plasmid. DNA sequences of some clones revealed sequence homology to attacin, cecropin, protease inhibitors. These clones were characterized by cDNA cloning, northern hybridization and southern hybridization.

07-054

CARBOXYLESTERASES OF *BOMBYX MORI* INDUCED BY INFECTION OF *E. COLI*,

T. Shiotsuki, and Y. Kato,
Department of Insect Physiology and Behavior, National Institute of Sericultural and Entomological Science, 1-2 Owashi, Tsukuba, Ibaraki 305 Japan.

There has been known many proteins, including anti-bacterial peptides, that are induced by bacterial infections. We found that ones of those induced proteins are carboxylesterases (CEs) in *Bombyx mori*. The CEs were induced after 24 hours not only by infection of *E. coli* but injection of lipopoly saccharides. The characteristics of the induced CE are different from juvenile hormone esterases or general CEs with no induction in terms of isoelectric points of the molecule. That is, pI values of the induced CE isozymes are approximately 6.0 in contrast with those of JHE (4.9) and general CE isozyme (4.8). The characteristics and function of those CEs are under investigation.

07-055**ISOLATION AND CHARACTERIZATION OF A NOVEL TYPE OF ANTIBACTERIAL PEPTIDE FROM THE SILKWORM, *BOMBYX MORI***

S. Hara, M. Yamakawa¹

Noda Institute for Scientific Research, Noda Noda, Japan - 1
Laboratory of Biological Defense, National Institute of Sericultural and Entomological Science, Ohwashi Tsukuba, Japan

A novel antibacterial peptide that shows antibacterial activity against *Staphylococcus aureus* was isolated from the immunized hemolymph of the lepidopteran, *B. mori*. This peptide (named moricin) consisted of 42 amino acids and was highly basic. Moricin indicated no significant similarity with other antibacterial peptides. Moricin showed antibacterial activity against several Gram-negative and -positive bacteria and had a higher activity against Gram-positives than cecropin B₁, an antibacterial peptide of *B. mori*. Moricin was inducible by bacterial injection. These results suggest that moricin is a novel member of antibacterial peptides and is responsible for the antibacterial activity in *B. mori* against Gram-positive bacteria.

The effects of moricin on bacterial and liposomal membranes indicated that a target of moricin is the bacterial cytoplasmic membrane. The results also suggest that the N-terminal portion of moricin, containing a predicted α -helix, is responsible for an increasing in the membrane permeability.

To obtain a large amount of this peptide, a production system in *Escherichia coli* was also constructed.

ORIGINS AND GENE FLOW IN COLORADO
POTATO BEETLE

Peter Follett & George Roderick, Center for Conservation Research and Training, University of Hawaii at Manoa, USA

Geographic structure and gene flow were estimated in Colorado potato beetles from native and agricultural habitats using protein electrophoresis and mtDNA. Using electrophoretic data, estimates of gene flow, N_{em} (calculated from theta) were 3.8 and 14.5 for populations from native and crop habitats, respectively, over the same geographic scale (approx. 500 km). Populations were sampled over time to examine year-to-year variation in geographic structure and assess genetic equilibrium. The estimate of N_{em} from mtDNA analysis of 10 populations from across the U.S. was 0.7. Genetic data is used to shed light on several hypotheses concerning the shift from native hosts to potato.

08-001

GENETIC STRUCTURE IN FRAGMENTED RELICTUAL POPULATIONS: HINTS FROM *DOLICHOPODA* CAVE CRICKETS

D.Cesaroni, G.Allegretti, V.Sbordoni

Dipartimento di Biologia, Università Tor Vergata, Roma, Italy

Evolutionary divergence and speciation in *Dolichopoda* cave crickets is essentially a geographic process. The model assuming fragmentation of a widespread epigean species and isolation of small populations in cave refugia, where divergence is mainly driven by genetic drift, appears suitable for *Dolichopoda*, where a metapopulation structure is often revealed.

The degrees of genetic structuring, as measured by Wright's F_{st} , were calculated for multiple combinations of populations at different geographic scales. F_{st} and m (migration rate) values were calculated on the basis of polymorphic loci and estimated population sizes on different groups of *Dolichopoda* populations by considering geographic windows progressively smaller. Comparisons among different geographical windows indicate that F_{st} and m values depend on the proximity between populations and the habitat structure surrounding caves. As expected, m values increase as the window scale decreases, and migration is actually detectable only between very proximate populations. At this scale, the extent of gene flow varies between populations sampled in areas with different bioclimatic conditions. Groups of populations from coastal mediterranean habitats are genetically more structured than those living in montane mesophilous forest, as supported by records of *Dolichopoda* in pitfall traps.

Population structure shapes the patterns of geographic variation of allozyme frequencies. Improvement of geostatistical tools to represent and analyze geographic variation of multivariate sets of characters helps to clarify, through the comparative study of patterns of variation at different geographic scales, the shaping, and the tempo and mode, of species formation. By this way, allopatric populations may be represented as genetic landscapes in the geographical space.

08-003

INTRON SIZE VARIATION TRACES THE WORLD-WIDE COLONISATION HISTORY OF THE MEDFLY *CERATITIS CAPITATA*

L. Gomulski¹, P.A. Morandi¹, S. Brogna^{2,3}, K. Bourtzis², C. Savakis², and G. Gasperi^{1,4}

¹Department of Animal Biology, University of Pavia, Pavia, Italy.

²IMBB-FORTH, Heraklion, Crete, Greece. ³Department of Genetics, University of Cambridge, Cambridge, UK. ⁴Institute of Zoology, University of Sassari, Sassari, Sardinia, Italy.

The 1st intron of the *Adh1* gene is unexpectedly long in *C. capitata* compared to that of *D. melanogaster*, and contains a sequence homologous to the *mariner* element of *Drosophila mauritiana*.

Using PCR, the *Adh1* first intron was isolated from 27 populations throughout the range of *C. capitata*. Eighteen size variants were found, ranging from 1400 bp to 3450 bp, each falling into one of four distinct size categories. The number of size variants is highest in populations from within the supposed ancestral range of *C. capitata*, i.e. Kenya. The degree of polymorphism declines rapidly towards the periphery of the global distribution, where one finds a subset of two or three size variants. The same trend of decreasing variation from the putative source area to the derived populations has previously been found using RAPD and allozyme methods in wild populations and laboratory strains of *C. capitata*. The intron variant frequency data was used to construct dendrograms to infer the relationships between the different wild populations.

The extent of homology between the different intron variants was analysed by means of their restriction maps. The four size categories can be explained by three major differences in their maps. The small intron category lack the *mariner*-like element. The medium and the long and very long intron categories all possess the *mariner*-like element but differ in the presence and size of an insertion/deletion in the second half of the intron. Variation within each category appears to be due to small insertions/deletions throughout the intron. Each of the two widely spread intron size variants were found to be identical in all the peripheral populations analysed. In the ancestral populations, however, restriction site polymorphisms were found in the variants. This further supports the derived nature of the peripheral populations and emphasises the restricted level of variation within and between these populations.

08-004

INVASION GENETICS AND PHYLOGEOGRAPHY OF THE MEDITERRANEAN FRUIT FLY: DNA SEQUENCES FROM MULTIPLE NUCLEAR LOCI

G.K. Roderick, F.X. Villablanca, and S.R. Palumbi

Center for Conservation Research and Training, University of Hawaii, Honolulu, HI 96822 USA.

Biological invasions generally start from low initial population sizes, leading to reduced genetic variation in nuclear and especially mitochondrial DNA. Consequently, genetic approaches to invasion history and population structure of many exotic pests and pathogens are difficult. For example, during invasions over the past century populations of the Mediterranean fruit fly, *Ceratitis capitata*, have lost 60 to 70 % of ancestral genetic variation at nuclear loci and a staggering 96 % of variation in mitochondrial DNA. This result has thwarted the use of genetic methods to understand the invasion history of Medflies. We present a new approach to invasion genetics that measures novel DNA sequence variation within introns from multiple nuclear loci. Not only are such loci variable, even within recent populations in both California and Hawaii (USA), but also they suggest that the number of emigration events from Africa were relatively few. Intron variation in species such as the medfly allows high resolution genetic characterization of invading populations and the potential to identify the numbers of colonization events and their sources.

08-005

EVIDENCE, USING GENETIC MARKERS, OF RESTRICTED GENE FLOW (MIGRATION) WITHIN AND BETWEEN BRITISH POPULATIONS OF THE DAMSON-HOP APHID *PHORODON HUMULI* SCHRANK (HEMIPTERA : APHIDIDAE)

H.D. Loxdale & C.P. Brookes

Department of Entomology & Nematology, IACR-Rothamsted, Harpenden, Hertfordshire, U.K.

The damson-hop aphid, *Phorodon humuli* Schrank, is a serious pest of hops in England. It is holocyclic (with obligatory sexual phase) and host alternating. From suction trap data, *P. humuli* aerial densities are known to be highest in the main hop growing regions viz. Hereford (mid-west) and Kent (south-east), some 260 km. apart. The aphid is now resistant to several insecticides. This is, in part, conferred by elevated (carboxyl)esterase activity, ranging from low in susceptible to high in very resistant strains.

Enzyme markers separated by gel electrophoresis, including carboxylesterase, have been used to examine the degree of genetic heterogeneity among *P. humuli* subpopulations on both its hosts (*Prunus* spp. (primary host) and hop, *Humulus lupulus* (secondary host)). The esterase data revealed heterogeneity among subpopulations, with a higher mean frequency of elevated esterase genotypes in the hop growing regions. Similarly, allele and genotype frequencies for another enzyme (6PGD) were also heterogeneous, even between subpopulations sampled at less than 30 km. apart in each of the two regions surveyed (especially from *Prunus*), whilst allele and genotype frequencies sometimes remained stable over a number of summers. Also, 6PGD genotype frequencies were sometimes in, or close to, Hardy-Weinberg expectations, even for parthenogenetically-reproducing aphids infesting the secondary host, hops. These data sets suggest that there is restricted inter-population gene flow, and hence migration, in this species. Presently, DNA data (RAPD) are being gathered to reveal the 'fine-grained' genetic structure of populations. The data are discussed in the light of previous studies on the population genetics of aphids using molecular markers (allozymes and DNA).

08-006

MOLECULAR MARKERS LINKED TO LIFE CYCLE VARIATION IN THE CEREAL APHID *RHOPALOSIPHUM PADI* L. (HOMOPTERA: APHIDIDAE)J.C. Simon, D. Martinez-Torres¹, A. Moya¹, A. Latorre¹, P.D.N. Hebert²

Laboratoire de Zoologie, INRA, Le Rheu, France - 1 Departament de Genetica, Universitat de Valencia, Burjassot, Spain - 2 Department of Zoology, University of Guelph, Guelph, Canada

Although most aphids reproduce by cyclical parthenogenesis, some species show variation in their mode of reproduction leading to life cycle polymorphism. Among the latter, *Rhopalosiphum padi* is particularly interesting since its populations may be a mixture of holocyclic clones (cyclical parthenogens), anholocyclic clones (obligate parthenogens) and androcyclic clones (producing some males in addition to parthenogenetic females). In this study, we analyzed mitochondrial DNA, RAPD and SCAR markers in *R. padi* as well as plasmid DNA of its endosymbiont to determine the genetic relationships between its sexual and asexual populations and to develop molecular tools for the characterization of its life cycle variants.

A strong relationship between life cycle and mtDNA as well as plasmid DNA was found: all holocyclic clones carried haplotypes II or III while most of the anholocyclic or androcyclic clones were haplotype I. The restriction site analysis on these two maternally inherited molecules suggested an ancient origin of asexual populations in *R. padi* followed with interrupted gene flow with sexuals. However, evidence of occasional gene flow between sexual and asexual lineages, presumably mediated by androcyclic males, was also provided and its consequences on the evolution of anholocyclic populations were evaluated. Lastly, we identified a RAPD marker linked to the life cycle variation in *R. padi* based on a bulk segregant analysis on F2 progeny of crosses between holocyclic and androcyclic clones. This marker was converted into a SCAR and its first applications on natural populations are presented.

08-007

CHROMOSOMAL LOCALIZATION OF A HIGHLY REPEATED *ECORI* FRAGMENT IN *MEGOURA VICIAE* (HOMOPTERA, APHIDIDAE) BY NICK TRANSLATION AND *IN SITU* HYBRIDIZATION.

D. Bizzaro and G.C. Manicardi.

Dipartimento di Biologia Animale, Università di Modena, Modena, Italy.

To investigate the genome of the aphid *Megoura viciae* at the molecular level, we studied total DNA by agarose gel electrophoresis after cleavage with different restriction endonucleases. *EcoRI* digestion produced a highly repeated DNA fragment, about 600 bp long. The contribution of this *EcoRI* element to the total genome of *M. viciae* has been estimated at 6% by means of densitometric scanning of photographs of agarose gels. The chromosomal localization of this satellite DNA, investigated by fluorescent *in situ* hybridization (FISH), constantly showed one main and two secondary fluorescent bands on the X chromosome, all corresponding to C-positive heterochromatic areas. These results are in full accordance with the data obtained by *in situ* nick translation experiments carried out after *EcoRI* digestion, and clearly demonstrate that the major fraction of *M. viciae* heterochromatin, which consists of *EcoRI* fragments, is essentially located on the X chromosome. Our data represent a substantial contribution to a better understanding of genome organization in *M. viciae*. Moreover, the utilization of the *EcoRI* restriction fragment as a molecular probe to be tested on DNAs obtained from several species, may represent a valuable tool for investigating taxonomic and evolutionary relationship in aphids.

08-008

INVESTIGATION OF THE UNDERLYING CAUSES OF HOST-BASED GENETIC VARIATION IN ASEXUAL POPULATIONS OF THE GRAIN APHID SITOBION AVENAE (F.) (HEMIPTERA: APHIDIDAE)

G. Lushai¹, P.J. De Barro², T.N. Sherratt³ & N. Maclean¹

¹ Department of Biology, University of Southampton, Southampton, Britain - ² Division of Entomology, CSIRO, Canberra, Australia- ³ Department of Biological Sciences, University of Durham, Durham, Britain

The grain aphid *Sitobion avenae* (F.) was collected from winter wheat and adjacent cocksfoot in southern Britain. Genetic variation between individuals was then investigated using multilocus probes. Aphids caught on wheat and cocksfoot in spring had highly characteristic genetic profiles, indicating host-based genetic similarity. However, this host-based genetic structuring became less distinct over time, and may have been as a result of local movement of aphids from cocksfoot to wheat.

In choice chamber experiments, winged summer forms preferred to colonise wheat rather than cocksfoot. Furthermore, those aphids collected from cocksfoot showed a lower preference for wheat than those collected from wheat. In performance experiments wingless forms generally had higher weight, fecundity and survival when reared on their host of origin. In both experiments, rearing aphids on alternate hosts over successive generations had a significant conditioning influence. Overall, the study reveals host-based genetic variation in a largely asexual species, while the evidence for clonal variation in both preference and performance confirms the existence of two processes by which this genetic stratification can be generated and maintained.

08-010

WHAT IS AN APHID SPECIES?

R.L. Blackman

Department of Entomology, The Natural History Museum, London SW7 5BD, UK

The conceptual and practical problems of defining and recognising aphid species, and especially aphid pest species, will be discussed in the light of recent advances in our knowledge of their population structure, life cycle variations and interactions with host plants. A distinction is drawn between the conception of species as functional, interactive, co-evolving units of life, and the working definition of a species, that attempts the seemingly impossible task of imposing static limits on essentially dynamic situations.

With the advent of molecular tools that will enable us to study, and perhaps eventually to predict, changes in the genetic structure of aphid populations, how useful is the species "tag", and how far can we go with the recognition of taxa below the level of the species?

08-009

GENETIC DIFFERENTIATION, SPECIATION AND HOST PREFERENCES IN APHIDS OF THE *HYALOPTERUS PRUNI* COMPLEX (HOMOPTERA, APHIDOIDEA)

L. Bullini, P. Arduino, M.C. Mosco, S. Barbagallo¹

Dipartimento di Genetica e Biologia Molecolare, Università di Roma "La Sapienza", via Lancisi 29, I-00161 Roma, Italy - ¹ Istituto di Entomologia, Università di Catania, via Valdisavoia 5, I-95123 Catania, Italy.

Previous isozyme studies (Spampinato *et al.*, 1988) have shown that the *Hyalopterus pruni* complex includes at least three distinct biological species: *H.pruni sensu stricto* (primary host plants, plum and apricot trees), *H.amygdali* A (primary host, almond and occasionally peach trees), and *H.amygdali* B (primary host, peach and occasionally almond trees). Further research at 30 enzyme loci on various European populations of the *H.pruni* complex, both sympatric and allopatric, have allowed: *i*) to estimate their genetic divergence and evolutionary relationships; *ii*) to identify by molecular markers the three species and their possible hybrids, and to assess reproductive isolation; *iii*) to investigate host preferences in the field.

H.pruni and *H.amygdali* A, which show the lowest genetic divergence ($D_{Nei}=0.12$) were never found to share the primary host; on the other hand, *H.amygdali* A and *H.amygdali* B, the two genetically most differentiated ($D_{Nei}=0.32$), show a more similar trophic niche, as they share the same primary host wherever the preferential one is lacking. Moreover, the few interspecific F_1 hybrids detected in the field were in mixed populations of *H.amygdali* A and B living on the same primary host (peach trees). No gene exchange was observed between any of the three species (lack of backcross, recombinant or introgressed genotypes); their reproductive isolation is therefore demonstrated. The possible speciation processes occurred in this complex are discussed.

08-011

THE COEVOLUTION OF APHIDS (HOMOPTERA: APHIDOIDEA) AND THEIR BACTERIAL ENDOSYMBIONTS (*BUCHNERA APHIDICOLA*): MOLECULAR PHYLOGENETIC APPROACHES

N. A. Moran, P. Baumann¹, C. D. von Dohlen²

Department of Ecology and Evolutionary Biology, University of Arizona USA - ¹ Division of Microbiology, University of California at Davis USA- ² Division of Biological Sciences, Idaho State University USA

Molecular phylogenetic analyses indicate that aphids and their bacterial endosymbionts have cospeciated since the time of an infection of a common ancestor of extant members of the Aphidoidea, over 100 million years ago. Studies of the tryptophan biosynthetic pathway within the endosymbionts have demonstrated that the genes for the rate-limiting step are amplified on plasmids within the Aphididae, allowing overproduction of this nutrient for the aphid host. Phylogenies derived independently using sequences of genes borne on these plasmids, on the endosymbiont chromosome, and on the aphid mitochondrial chromosome are similar, supporting the hypothesis that plasmid genes were derived from the chromosome and that all genomes are vertically transmitted.

Molecular phylogenetic studies of the Aphidoidea and of major groups within the Aphididae are also presented.

08-012

MICROSATELLITE TRACKING OF PHYLOGENY AND RECENT EVOLUTION OF *SITOBION* (HEMIPTERA: APHIDIDAE)

P. Sunnucks and D.F. Hales

School of Biological Sciences, Macquarie University, Sydney, Australia.

Sitobion is a genus of about 75 species, of which almost half feed on Gramineae, often causing economic damage. Two species of probable East Asian origin, *S. miscanthi* and *S. nr fragariae*, occur on grasses in Australia. *S. miscanthi* is thought to have reached Australia naturally, prior to European settlement, but *S. nr fragariae* has been recognised here only since the 1960s. Many possible synonymies of the grass-feeding Asian *Sitobion* spp. have been proposed. Further confusion arises from the existence in Australia of at least five chromosomal races of *S. miscanthi*.

We have used microsatellite DNA analysis to investigate the phylogeny of *Sitobion* spp. feeding on Gramineae, and to examine the local evolution of the two species occurring in Australia. Both are assumed to be continuously parthenogenetic here, and this hypothesis is also tested. The work is the first to examine the genetics and evolution of parthenogenetic invading species using microsatellites.

Four microsatellite loci have been scored for a range of geographically separated Australian populations of *Sitobion*, as well as non-Australian *S. avenae*, *S. fragariae*, and *S. akebiae*. Along with sequence data from single locus nuclear genes in some species from hosts other than grasses, these data enable us to present a phylogeny of the species considered. There seems to have been a single successful invasion of *S. nr fragariae* into Australia, while *S. miscanthi* is represented by survivors from two separate migrations. One of these has given rise to the 2n=18 and 19 chromosomal races, and the other to the 2n=17, 20 and 21 races. The gene pool within Australia is very limited, and there is no evidence of sexual reproduction by either species, in contrast to the situation in Asian and European populations.

08-014

AUTUMN COLOURS: A ROLE FOR APHIDS?

W.D. Hamilton, S. Brown

Department of Zoology, South Parks Road, Oxford OX1 3PS, England

A crude but objective scoring of the autumn colours of deciduous trees in North America and Europe reveals independent significant positive correlations of the red and (more strongly) the yellow of trees with incidence per tree species of single primary host aphid species. Although coefficients are always positive, correlations of the colours with aphid parasitism specific only within genus, or within 2, 3, or >3 genera, are in no case significant. Applying phylogenetic regression (A. Grafen) and controlling for several possible confounding variables of tree characteristics and geography hardly changes the results.

Aphids use colour vision to find hosts. Primary hosts are ancient associates for most aphids so that aphids, especially those host-specific, will have damaged hosts throughout long co-evolution. This will have occurred through conveyed virus as well as directly through feeding.

It is postulated that trees synthesise pigments in leaves about to be shed because they serve as handicap demonstrations of tree vigour. They deter so far as possible aphids from landing and egg-laying: The 'message' is that a strong tree will mount a strong defence, probably chemical, against aphid feeding in spring.

Other insect groups possessing colour vision may be involved and this is especially likely for reds for which our correlation is weak. Work is needed to test all the above suggestions.

08-013

THE PHYLOGENETICS AND HISTORICAL BIOLOGY OF THE APHID TRIBE CERATAPHIDINI (HOMOPTERA: APHIDOIDEA: HORMAPHIDIDAE)

D. L. Stern

Churchill College, Cambridge and Wellcome/CRC Institute and Department of Genetics, University of Cambridge, Cambridge, UK

To elucidate the evolution of several important traits within aphids I have been studying the molecular phylogenetics of the Cerataphidini. Using mtDNA sequence data I have estimated the phylogeny for over 35 species of the Cerataphidini. I have used this phylogeny to examine (1) the evolution of sterile soldiers on both the primary and the secondary host, (2) the evolutionary reduction of complex life cycles, (3) the evolutionary replacement of one endosymbiont by another, and (4) the evolution of gall morphology. In addition, the DNA sequence data has proved useful in determining the life cycles of tropical aphid species that have been otherwise difficult to study.

08-015

THE EVOLUTIONARY HISTORY OF APHIDS AND A HYPOTHESIS ON THE COEVOLUTION OF APHIDS AND PLANTS

O. E. Heie

Department of Biology, DLH, Emdrupvej 101, DK-2400 Copenhagen NV, Denmark

Fossil aphids, including several specimens recently found in amber from the Cretaceous and the Lower Tertiary, not yet described, and comparison between the aphid fauna of the past and the recent fauna, indicate two major faunal changes, which are confirmed by the new findings. The first change happened at or close to the Cretaceous-Tertiary boundary, 50-70 million years ago. The composition of the faunas, respectively about 75-80 million old and about 35-45 million years old, are described and compared. Most aphid families present in the Cretaceous became extinct before the Lower Tertiary, the period, in which the Baltic amber was produced. In the Lower Tertiary most recent families were present, but the families Aphididae and Lachnidae were much less rich in species than they are today. These changes are described as consequences of changes of the flora, from gymnosperms to angiosperms, and from predominantly woody angiosperms to herbs, especially herbs belonging to the plant families Poaceae and Asteraceae, which became rich in species during the Upper Tertiary and now contain the hosts of most aphids.

Among new species of Cretaceous age are representatives of the families Canadaphididae and Palaeoaphididae, previously only known from Canadian amber deposited in a secondary site. Two additional specimens of *Canadaphis carpenteri* Essig, 1937, show a long rostrum, not visible in the holotype. The presence of siphuncular pores shows that Canadaphidoidea is a synonym of Aphidoidea. Among the representatives of Palaeoaphididae is a member of a new genus with long rostrum and bilobed posterior end of the abdomen. Instead of siphuncular pores it carries small cuticular fields with very small pale spots.

08-016

TWENTIETH-CENTURY MORPHOMETRICS
What We Know, What We Don't

Fred L. Bookstein
University of Michigan, Ann Arbor, Michigan, USA

At the core of contemporary morphometrics, the quantitative study of biological shape variation, is a synthesis of two originally divergent methodological styles. Conventional multivariate analysis of covariances or correlations among multiple measures of shape or size sometimes results in optimal statistical descriptions of group differences, but this approach ("multivariate morphometrics") cannot properly exploit the origin of our data in measurements on specimens or pictures. Another tactic much more in the spirit of observational biology emphasizes the direct visualization of changes in biological form by comparative drawings upon which relevant measurements or deformation grids are sketched. But it proved very difficult to convey the variation and covariation of aspects of form, as distinct from pairwise contrasts, in diagrams like these. It has thus been clear for decades that some methodological synthesis was urgently needed.

The solutions that have been worked out for this problem of synthesis differ for the different data structures typical in our field. All spring from new, more careful consideration of the way "size and shape data" arise in quantitative biology. One new abstraction is crucial: the space of all shape measures, for data of the relevant type (weights, landmarks, etc.), "in the vicinity of an average form." The structure of this space varies according to the nature of the data. A suite of net size measures, such as overall organ weights or volumes, is approached via the study of all allometric ratios (log-linear combinations). Modern variants of principal-components analysis are well-suited to investigations of this sort. When data arise as a set of measured distances, whether or not between landmarks, we may exploit the fact that ratios of distances are, themselves, shape measures. The special role of geometric shape as distinct from allometric shape emerges here because of its power for generating new descriptions of findings. Finally, we have just recently designed a new, startlingly powerful version of multivariate analysis for data that are coordinates of landmark points. Here, one single analysis combines statistics and graphical display of findings for all possible shape analyses simultaneously.

08-018

PHYLOGENETIC PATTERNS AND MORPHOMETRIC
DISTANCE IN LYGUS BUGS

R. G. Foottit
Biological Resources Division, Centre for Land and Biological
Resources Research, Agriculture and Agri-Food Canada, Ottawa,
ON, Canada

Lygus bugs (Heteroptera:Miridae) are plant-feeding insects causing economic losses to many crops in the Northern Hemisphere. Consequently *Lygus* species are the subject of much basic and applied research. However, they are taxonomically difficult, due to subtle character differences and character variability. This genus has recently been subjected to a broad systematic analysis involving traditional morphological characters, morphometric and molecular data and a range of phylogenetic methods in order to resolve the relationships among the species. This paper compares the results from different approaches to determining morphological distance among *Lygus* species using different data sources and discusses the results of different methods of comparison, particularly between a partially resolved molecular phylogeny and phylogenies derived from morphometric sources.

08-017

EVOLUTION OF WING FORM AND VENATION IN THE *DROSOPHILA*
MELANOGASTER SUBGROUP (DIPTERA, DROSOPHILIDAE)

M. Baylac
Muséum national d'Histoire Naturelle, Laboratoire d'Entomologie, 45,
rue Buffon, Paris, France
Wings of *Drosophila* have been characterized by fourteen homologous landmarks on both sexes of the eighth species of the *melanogaster* subgroup, the three mitochondrial types of *D. simulans* (sil, sill and silli) as well as some interspecific F1 hybrids. Geometric morphometric analyses were done using Procrustes superimposition and Thin plate splines partial and relative warps. Species and sexes were separated by principal components and discriminant analyses. The overall misclassification was as low as 2.8 % and dealt mostly with *D. melanogaster* and *D. erecta*. The most important shape divergence was encountered within the monophyletic group build by *D. simulans*, *D. mauritiana* and *D. sechellia*. Within these three species, evolution of wing shape supports a sister-group relationships between *D. mauritiana* and *D. simulans*. These analyses helped to reveal hidden patterns of shape changes, which encompass clearly the classical longitudinal shift of the R1 apex. These shape patterns are analysed in relationships with intra- and interspecific allometries and in the light of wing compartments.

MORPHOMETRICS AND THE ANALYSIS OF
DEVELOPMENTAL PROCESSES

H. F. Nijhout
Department of Zoology, Duke University, Durham, NC USA
Morphology is the product of developmental processes, and differences in morphologies are due to differences in those processes. Although it is possible to define arbitrary functions that accurately describe the relationship between two morphological traits, and arbitrary discriminant functions that can accurately distinguish between different morphologies, in order to understand the development and evolution of a character suite the descriptive model should also capture the essence of the processes that gave rise to those relationships and differences.
The morphometric relationship between two characters can be interpreted in terms of differences in the parameters of a developmental model that can produce those characters. Two such analyses will be discussed. (1) The allometric relations among body parts in holometabolous insects are seldom linear. Most often they are curvilinear or broken and discontinuous. We have modeled the growth of imaginal structures and examined the consequences of inter-disk competition in the closed environment of the pre-pupa on the growth of disks. We show that non-linear and complex allometries are the consequence of normal growth processes of holometabolous insects. (2) Genetic crosses, experimental perturbation methods, and theoretical models, have revealed that the control mechanisms that regulate the development of lepidopteran color patterns are highly localized. Morphometric analysis of individual variation likewise reveals an almost complete lack of correlated variation among pattern elements. Together, the morphometric and experimental data reveal a highly flexible developmental system and help explain the great evolutionary radiation of color patterns and the ease with which adaptive patterns and accurate mimicry can evolve.

GROWTH STUDIES IN HEMIMETABOLOUS INSECTS: ANALYSIS OF ONTOGENETIC VARIATION AND CONSTRAINTS

Christian Peter Klingenberg

Department of Biological Sciences, University of Alberta, Edmonton, Alberta T6G 2E9, Canada

Hemimetabolous insects, especially those with a constant number of instars, provide an excellent opportunity to study ontogenetic variation. The molts are distinct ontogenetic stages corresponding among individuals and may be considered homologous across species for comparative studies. Longitudinal growth data are fairly easy to obtain by collecting exuviae from individually reared insects.

I present results of such an analysis in the water strider *Limnoporus canaliculatus* (Heteroptera: Gerridae). A new statistical technique made it possible to study the covariation among characters simultaneously within and across instars. The underlying model assumes that one common pattern not only underlies the variation within instars, but also the covariation among stages. The data from *Limnoporus* conform fairly well to this assumption.

Analyses of variation in instar-specific size measurements (cumulative data) differ from analyses of growth increments. Ontogenetic trajectories for cumulative size are strongly constrained and show only a few patterns of variation, which also have been found in studies of mammals and birds; these result from the part-whole relationships inherent in cumulative data, but do not reflect developmental processes in the study organisms. In contrast, incremental data show very little ontogenetic integration or constraints; this flexibility possibly accounts for the substantial interspecific variation of growth increments in the genus *Limnoporus*.

For a more complete understanding of the evolution of ontogenies, quantitative genetic experiments and field studies of life histories, the ecological aspect of ontogeny, should be combined with this morphometric approach.

INSTAR DETERMINATION USING FINITE MIXTURE ANALYSIS: Dyar's rule meets maximum likelihood

Bernard D. Flury and Cameron R. Currie

Size measurements, e.g., head capsule widths, have been used traditionally to identify instars in populations of insects. However, this is a difficult problem if the size distributions of different instars overlap. Ad-hoc methods are usually applied, such as counting the number of peaks in a histogram, or approximation of a multimodal histogram by a combination of several normal densities using least squares (McClellan and Logan 1994, Environ. Entomol. 23: 248-253, 1994). A more sophisticated approach is given by the methodology of finite mixture analysis, which allows to estimate the parameters of distributions that consist of homogeneous sub-populations mixed in unknown proportions. We give a non-technical introduction to finite mixtures and their estimation by maximum likelihood, and illustrate the technique using data measured on several insects with diverse life history strategies, such as forest defoliators and wood-boring beetles.

MORPHOMETRIC ANALYSES FOR FUNCTIONAL MORPHOLOGY

C. Loudon

Department of Entomology, Kansas State University, Manhattan, KS, USA

Morphological description is a necessary part of biomechanical or functional studies. However, it is not always obvious which morphological features are functionally relevant in a particular case; mechanical phenomena can scale in a nonintuitive or even a counterintuitive way with form. For example, sometimes large differences in size or shape are without functional correlation and sometimes even a small anatomical change will make a huge difference.

Can one look at the size and shape of an insect antenna and know anything *a priori* about its capacity to intercept chemical signals from the air? Using physical models based on the geometry of *Bombyx mori* antennae, an engineering technique was used to estimate the mass transfer coefficients of individual sensilla (the rate at which material can be exchanged between a structure and its surrounding environment). The results do scale with surface area as expected. However, the mass transfer coefficients are also sensitive to the proximity of other hairs. Thus another anatomical feature, the distance between hairs, is also functionally significant. The magnitude of this influence depends both on the speed of the air flow and the spatial distribution of the chemical signal.

08-023

SCALING SIZE TO FITNESS

W. E. Bradshaw, C. M. Holzapfel

Department of Biology, University of Oregon, Eugene, OR USA

Size at metamorphosis and adult size in mosquitoes is generally reduced if larvae experience higher temperatures, higher density, or reduced resources. The number of ovarioles in adult females increases monotonically with increased female mass and the number of eggs per batch, clutch, or ovarian cycle reflects this relationship. Size also affects adult survivorship. Survivorship may be a linear, exponential, or parabolic function of size. Individual fitness expressed as expected lifetime production of offspring is a product of survivorship and fecundity. The relative magnitude of size-dependent fecundity and size-dependent survivorship then determine whether fitness scales to a linear, logarithmic, exponential, or parabolic function.

08-024

EVOLUTION AND PHYLOGENY OF *WOLBACHIA*

J.H. Werren, Department of Biology, University of Rochester

Wolbachia are rickettsial bacteria that are widespread in arthropods and cause a variety of reproductive alterations in their hosts, including reproductive incompatibility, parthenogenesis and feminization of genetic males. These reproductive alterations are selectively advantageous for the microorganisms and have important evolutionary implications for evolution of their hosts. A phylogenetic study of *Wolbachia* using 16S ribosomal and protein coding regions reveals that these bacteria are diverse and undergo extensive horizontal transfer between different arthropod taxa. Phylogenetic data indicate that transfer between parasitic wasps and their insect hosts may occur. Parthenogenesis induction by *Wolbachia* appears to have evolved several times independently. Infections with 2 different strains of *Wolbachia* occur in some arthropod species. Finally, there is accumulating evidence that incompatibility *Wolbachia* may be a factor promoting reproductive isolation and rapid speciation in arthropods.

08-026

DIVERSITY OF FEMINIZING *WOLBACHIA* IN ISOPODS

D. Bouchon, T. Rigaud and P. Juchault
Université de Poitiers, URA CNRS 1975, Poitiers, France.

Wolbachia are strictly endocellular, vertically transmitted bacteria associated with insects and crustaceans. They are responsible for feminization, cytoplasmic incompatibility (CI) or parthenogenesis in their hosts, which enable them to increase their transmission in the host populations. By using PCR diagnostic primers we have found *Wolbachia* in 20 isopods : *Wolbachia* is widespread in Oniscidea occurring in all families and is also present in Asellota and Flabellifera. The taxonomic status of these microorganisms has been defined by sequencing parts of their 16S rDNA and *ftsZ* genes. The bacteria from Oniscidea hosts show a very low divergence. Even with the more variable *ftsZ* gene, some *Wolbachia* sequences are identical in host species belonging to different families. All these bacteria form a monophyletic group which belong to the B subdivision of *Wolbachia* whereas bacteria from Asellota and Flabellifera are more close to parthenogenesis and CI *Wolbachia* of insects. The lack of concordance between bacterial and host phylogenies indicates that the crustacean-infecting *Wolbachia* have undergone horizontal transfer amongst isopod lineages and may be between insects and crustaceans. Other results including success of microinjections of bacteria are consistent with the view that horizontal transfer has been predominant in the modern distribution of *Wolbachia*. Uninfected males and females of woodlice were inoculated by endosymbionts from 6 other species. Most of the recipient males were feminized by the inoculated bacteria showing their ability to induce feminization, symptom only known in crustaceans. Foreign *Wolbachia* were also able to live in most recipient females. However, the results varied from a successful transmission to the offspring to a detrimental effect on female fecundity. In the first case, the highly female-biased progenies always occurred when the donor and the recipient are sibling species. These results show that horizontal interspecific transfers can contribute significantly to the wide distribution of *Wolbachia* within terrestrial isopods, even if their success is not predictable.

08-025

PARTHENOGENESIS *WOLBACHIA* IN HYMENOPTERA

Richard Stouthamer
Department of Entomology, Wageningen Agricultural University,
Wageningen, The Netherlands

Female wasps infected with parthenogenesis *Wolbachia* are capable of producing daughters without mating. This type of infection has now been found in approximately 20 species of Hymenoptera spread over at least 6 families. Many more cases are suspected. The *Wolbachia* allows unfertilized eggs to become females by influencing the first mitotic division in the egg. The presence of these *Wolbachia* is associated with an aborted first mitotic division resulting in a fusion of the two sets of identical mitotic chromosomes. Thus the resulting diploid and therefore female offspring is 100% homozygous. In most species studied all individuals of a species are infected, but in a number of *Trichogramma* populations both infected and not-infected (i.e. sexual) wasps are found together. In such populations males will mate with the infected females and their sperm will be used for the fertilization of eggs. Such fertilized eggs become infected diploid females, whose genetic make-up consists of one set of chromosomes from the father and one from the mother. In such mixed populations the infected fraction of the population is not genetically isolated from the sexual forms. The infection with *Wolbachia* appears to have a substantial negative effect on the offspring production in infected females from such mixed populations. These negative effects on offspring production are not evident in those species where the infection has gone to fixation. The relationship between the parthenogenesis and incompatibility *Wolbachia* is not quite clear. Using phylogenetic methods it can show that the *Wolbachia* are divided in two groups, both groups contain incompatibility and parthenogenesis *Wolbachia*. Contrary to the situation in incompatibility infections where representatives of both groups can be found in one infected individual not double infections have been found to date.

08-027

TOWARDS A BETTER UNDERSTANDING OF THE MOLECULAR BASIS OF *WOLBACHIA*-MEDIATED CYTOPLASMIC INCOMPATIBILITY

S. L. O'Neill, H. R. Braig & T. Sasaki
Department of Epidemiology & Public Health, Yale University,
New Haven, CT USA

The phenomenon of *Wolbachia*-mediated cytoplasmic incompatibility has been known from insects for many years. However, an understanding of the mechanism of how *Wolbachia* is able to disrupt early fertilization events in insects has yet to be determined. We report on our efforts to unravel this system, including a method for *in vitro* cultivation of *Wolbachia* and characterization of the dominant *Wolbachia* protein found in insect testes. We provide indirect evidence that this protein may be functionally significant with regard to the expression of cytoplasmic incompatibility.

DISTRIBUTION OF WOLBACHIA AND CYTOPLASMIC
INCOMPATIBILITY IN MITES

J.A.J. (Hans) Breeuwer

Institute for Systematics and Population Biology, University of Amsterdam,
Amsterdam, The Netherlands

Wolbachia are a group maternally inherited bacteria that manipulate normal reproduction of their arthropod host to enhance their own transmission. They are widespread in insects, but are little studied in other arthropods except for a few isopods. *Wolbachia* are implicated as the cause of parthenogenesis in parasitic wasps, feminization of genetic males into functional females in isopods, reproductive isolation (cytoplasmic incompatibility) between and within many species (insects and an isopod) and yet others do not seem to have a noticeable effect on their host. Despite their widespread distribution in insects and various effects they have on their host, they form a monophyletic group of closely related group of intracellular bacteria based on 16S and *ftsZ* DNA sequences.

Mites (Order Acari) often show postzygotic reproductive isolation between populations and closely related species, but the genetic basis is not well understood. Presence of cytoplasmic incompatibility *Wolbachia* resulting in reduced crossability could be one explanation. Here I report on the widespread occurrence of *Wolbachia* in mites based on a PCR assay with primers specific for *Wolbachia ftsZ* gene, and their effect on the mite host. In the spider mite, *Tetranychus urticae*, *Wolbachia* cause cytoplasmic incompatibility. Crosses between infected and uninfected (antibiotic treated) mites resulted in increased embryo mortality among offspring. As in Hymenoptera, this spider mite is haplodiploid: females develop from fertilized eggs and males from unfertilized eggs. Cytoplasmic incompatibility in parasitic wasps typically results in all male offspring, because of paternal chromosome elimination which renders the egg haploid. Unlike parasitic wasps, cytoplasmic incompatibility in this spider mite resulted in mortality among fertilized eggs: the number of sons (unfertilized eggs) is not affected. The widespread presence of *Wolbachia* in mites may very well parallel the situation in insects. Moreover, predatory and parasitic mites may play a role in horizontal transmission of *Wolbachia* not only among mites but also among insects.

COMPARISON OF MOLECULAR AND REPRODUCTIVE
VARIABILITY ASSOCIATED TO CYTOPLASMIC GENOMES IN
THE MOSQUITO, *CULEX PIPPIENS*

F. Rousset and T. Guillemaud

Laboratoire Génétique et Environnement, Institut des Sciences de
l'Evolution Montpellier, France.

Bacteria of the genus *Wolbachia* are responsible for reproductive incompatibilities between *Culex pipiens* mosquitoes assumed to harbour different *Wolbachia* strains. Past work has suggested the existence of considerable polymorphism with regards to incompatibility properties in populations of this mosquito. So far, it has been found that in other host species (*Drosophila simulans*, *Aedes albopictus* and *Nasonia vitripennis*) incompatible infected strains harbour different *Wolbachia* strains that can be distinguished by sequences of their 16S rRNA and *ftsZ* protein gene. To investigate the presence of similar multiple infections in mosquitoes we have sequenced a fragment of the *ftsZ* protein gene of symbionts from strains of various geographic origin, taxonomic (subspecies) affiliation, and with different compatibility relationships. We found no variation. We have also sequenced the control region of *Culex* mtDNA in these strains and found a low level of variation. This suggests that cytoplasmic genomes of most *Culex pipiens* mosquitoes have a relatively recent common ancestor, and that differentiation of incompatibility types in this species has occurred since this recent common ancestor. However, the exact factors responsible for this differentiation are still unknown.

08-032

ICE AGE RANGE CHANGES, HYBRID ZONES & SPECIATION
G.M.Hewitt. Biological Sciences - UEA. Norwich, NR4 7TJ, UK.

The genetic effects of pleistocene ice ages are approached by deduction from paleoenvironmental information, by induction from the genetic structure of populations and species, and by their combination to infer likely consequences. (1) Recent paleoclimatic information indicate rapid global reversals and changes in ranges of species which would involve elimination with spreading from the edge. Leading edge colonisation during a rapid expansion would be leptokurtic and lead to homozygosity and spatial assortment of genomes. In Europe and North America, ice age contractions were into southern refugia, which would promote genome reorganisation. (2) The present day genetic structure of species shows frequent geographic subdivision, with parapatric genomes, hybrid zones and suture zones. A survey of recent DNA phylogeographic information supports and extends earlier work. (3) The grasshopper *Chorthippus parallelus* is used to illustrate such data and processes. Its range in Europe is divided on DNA sequences into 5 parapatric races, with southern genomes showing greater haplotype diversity - probably due to southern mountain blocks acting as refugia and northern expansion reducing diversity. (4) Comparison with other recent studies shows a concordance of such phylogeographic data over pleistocene time scales. (5) The role that ice age range changes may have played in changing adaptations is explored, including the limits of range, rapid change in new invasions and refugial differentiation in a variety of organisms. (6) The effects of these events in causing divergence and speciation are explored using the grasshopper *Chorthippus* as a paradigm. Repeated contraction and expansion would accumulate genome differences and adaptations, protected from mixing by hybrid zones, and such a composite mode of speciation could apply to many organisms.

PALEOINTROGRESSION AND REINFORCEMENT IN INSECTS
Rossella Cianchi

Dipartimento di Genetica e Biologia Molecolare, Università di Roma "La Sapienza", via Lancisi 29, I-00161 Roma, Italy

The role of reinforcement in increasing and completing reproductive isolation between taxa in secondary contact, by selection against hybrids, has been recently much debated (cf. Butlin, 1985, 1987; Howard, 1993). Crucial points in order to demonstrate reinforcement are: i) to show a lowering of gene flow between interbreeding taxa since they first came into contact; ii) to detect differences in ecological or behavioural prezygotic isolation mechanisms, increasing assortative mating in sympatry.

A number of cases are reviewed in insects, among which the swallowtail *Papilio machaon* and its Sardo-Corsican relative *P. hospiton* (Ungaro *et al.*, in press); the ctenuchid moth *Syntomis* (= *Amata*) *phegea* and its sibling relatives *S. ragazzii* and *S. marjana* (Cianchi *et al.*, in press); the Mediterranean rock-pool hydrenid beetles *Ochthebius quadricollis*, *O. sp. A* and *O. brevicollis steinbuehleri*. (Urbanelli *et al.*, in press). In each case the occurrence of present hybridization and eventual gene exchange is estimated by isozyme markers, as well as the extent of paleointrogression phenomena (*i.e.*, the presence of 'alien' alleles in a species gene pool, owing to past hybridization). Similar cases have been recently found in other animal groups, *e.g.* in amphibians: *Hyla* treefrogs (Verardi *et al.*, in press) and *Hydromantes* plethodontid salamanders (Cimmaruta *et al.*, in press).

08-033

SUTURE ZONES IN INSECTS

Charles L. Remington

School of Forestry & Environmental Studies, Yale University, New Haven, CT 06520 U.S.A.

Suture zone theory, announced in 1968, has now had many years of testing and elaboration, with commentary by various investigators.

Three questions to be addressed now are: 1) How extensively are hybrid zones concentrated in suture zones? 2) How long is the duration of clear signals from hybridization following the origin of a suture zone? 3) What is the global geography of the suture-zone phenomenon? There is a close linkage between natural hybridization and suture-zone phenomena, and they will be addressed together.

08-035

BARRIERS TO FERTILIZATION AND REPRODUCTIVE ISOLATION: INSIGHTS FROM A CRICKET HYBRID ZONE

Daniel J Howard, Department of Biology, New Mexico State University, Las Cruces, NM 88003

The ground crickets, *Allonemobius fasciatus* and *A. socius* meet in a mosaic hybrid zone in eastern North America. A characteristic feature of mixed populations is the presence of many "pure" species individuals, a finding which suggests a relatively high degree of genetic isolation between the two taxa. Years of investigation indicate that the isolation is due to a post-insemination barrier to fertilization. I will discuss: factors which may drive the rapid evolution of barriers to fertilization; the isolating potential of such barriers; and our progress in understanding the genetic control of the barrier to fertilization in *Allonemobius*.

08-036

THE ROLES OF CHROMOSOME STRUCTURE, LIFE HISTORY TRAITS AND CLIMATE IN MAINTAINING GENETIC ISOLATION BETWEEN TWO HYBRIDISING TAXA OF THE GRASSHOPPER *CALEDIA CAPTIVA* (ORTHOPTERA: ACRIDIDAE).

D.D. Shaw, F.R. Groeters, M. Hurst

Eukaryote Chromosome Organisation, Research School of Biological Sciences, Australian National University, Canberra, Australia

The hybrid zone between the Moreton and Torresian taxa of *Caledia captiva* is extremely narrow and is defined by a series of chromosomal differences that involve all members of the genome ($2n = 22 + XX/XO$). The transition from a Moreton metacentric to a Torresian acrocentric genome occurs over a distance of only 800 metres. Hybrid breakdown among F₂ and backcross generations is 100% and 50% respectively. Similarly, allopatric populations of the Moreton and Torresian taxa show high levels of positive assortative mating ($I = 0.55$). Despite the presence of high levels of postmating isolating factors, high levels of genetic differentiation ($D = 0.23$) between the taxa and the presence of genetic variation for pre-mating isolation, mating within the zone is random with no evidence of disruptive selection favouring positive assortative mating.

An explanation of this apparent anomaly may relate to the instability and movement of the zone during periods of climatic change. Analyses of past biogeographical and current climatic patterns in the area indicate that the zone may have moved during periods of climatic change and its current location is determined by rainfall and temperature seasonality gradients. This is supported by the presence of diagnostic Moreton molecular and biochemical markers in Torresian populations up to 400km to the north of the zones current location.

During the past 5 years the zone has been subjected to drought conditions which predictably should favour the Torresian taxon. An examination of the chromosome structure of the zone has revealed major changes in its composition with evidence of highly significant and asymmetrical movement of Torresian individuals across the zone into predominantly Moreton populations.

The consequences of these rapid and asymmetrical changes to the composition of the zone will be discussed in the context of their impact upon speciation processes in parapatry.

08-037

THE ECOLOGY OF A HYBRID ZONE - CONTACT BETWEEN *HELICONIUS HIMERA* AND *HELICONIUS ERATO* CYRRIA
Chris Jiggins, Galton Laboratory, Department of Biology, University College London, 4 Stephenson Way, London, NW1 2HE

Hybrid zones between colour pattern races of *Heliconius* butterflies are maintained by frequency dependent selection acting directly on colour patterns and generally independent of habitat. This study concerns a hybrid zone between two forms which are considered good species, because intermediate forms are rare in the area of contact.

Laboratory experiments have shown that this is due to a strong pattern of assortative mating between the species, without any evidence of hybrid inviability. This talk will concern ecological aspects of the hybrid zone. The cline between the forms is extremely narrow, which suggests that it cannot be explained solely by selection on colour pattern. It is closely correlated with a habitat transition between wet and dry forest, but there is no evidence of divergence in host plant preferences either in the field or laboratory. This suggests that the cline is maintained by competition between the species at the habitat boundary, perhaps for host plant resources. Speciation, in this case, appears to be associated with divergence in habitat and colour pattern.

08-038

HYBRID ZONES AND SPECIATION IN *HELICONIUS* (LEPIDOPTERA: NYMPHALIDAE)

James Mallet, Galton Laboratory, Department of Biology, University College London, 4 Stephenson Way, London, NW1 2HE

I give examples of hybrid zones in *Heliconius*, a genus of warningly coloured, mimetic butterfly from South America. There is a continuum from (1) clines between geographic colour pattern forms or races, to (2) examples of hybridization between species that remain virtually distinct, apart from a few hybrids, to (3) parapatric contact zones between species without hybridization. Studies of selection, migration and evolution in this continuum of hybrid/contact zones give important insights into the process of speciation.

08-039

SPECIATION BY HYBRIDIZATION IN STICK INSECTS AND *OTIORHYNCHUS* WEEVILS

Luciano Bullini

Dipartimento di Genetica e Biologia Molecolare, Università di Roma "La Sapienza", via Lancisi 29, I-00161 Roma, Italy

Molecular markers are providing increasing evidence of the occurrence of hybrid species in various insect groups. Speciation by hybridization is a sympatric, allopatric, almost instantaneous event (quantum speciation) giving rise to a new species that combines the genomes of two distinct parental taxa. Individuals of hybrid species, by further hybridizing with bisexual relatives, occasionally give rise to new hybrid forms, often of higher ploidy level (*reticulate evolution*). Insect hybrid species show either clonal (thelytokous parthenogenesis, gynogenesis) or emiclonal (hybridogenesis) reproduction.

A number of cases are examined, among stick insects (genera *Bacillus*, *Clonopsis* and *Leptynia*) and weevils (genus *Otiorynchus*). Short- and long-term evolutionary consequences of speciation by hybridization are discussed.

08-040

TAXON SAMPLING AND HIGHER ORDER MOLECULAR PHYLOGENY: ANALYSIS OF mtDNA SEQUENCES AMONG ORTHOPTEROID INSECTS

Paul Flook
Zoologisches Institut der Universität Basel, Rheinsprung
9, Basel 4051, Switzerland, Email:
flook@ubaclu.unibas.ch

In many of the older insect groups (e.g. the hemimetabolous orders), multiple substitution events in DNA sequences, and particularly mtDNA, have proved a formidable obstacle to phylogenetic reconstruction. Various strategies are available that permit investigators to circumvent problems associated with site saturation. One approach is to use weighting schemes that compensate for the high frequency of certain types of substitutions. Alternatively, an attempt can be made to reduce long branch lengths in phylogenies, where multiple substitutions tend to result in random joining of taxa. I have investigated this second approach using a large, representative sample of orthopteroid mitochondrial DNA sequences, which can be separated into several distinct groups (superfamilies). Numbers of taxa per group were varied and the efficiency of phylogenetic reconstruction assessed by consistency index, bootstrap and PTP analysis. The results confirm that small increases in sampling can have considerable influence on phylogenetic reconstruction. However, the addition of sequences has the advantage of improving the identification of homology in the alignment, and so further augmenting the phylogenetic analysis. This raises the question of whether intensive taxonomic sampling of short DNA sequences may be a more effective strategy of approaching phylogenetic problems than concentrating on longer sequences from smaller taxonomic samples.

08-042

MITOCHONDRIAL DNA VARIABILITY IN THE HONEY BEE (*Apis mellifera* L).

L. Garnery
Laboratoire Populations Génétique et Evolution, Avenue de la terrasse
91198 Gif-sur-Yvette

The mt DNA variability of the honey bee *Apis mellifera* has been investigated by restriction enzyme polymorphism and sequencing. The two types of results are largely congruent and a clear picture emerged from these analyses. Colonies and subspecies are clustered into three major lineages called A, M, and C, geographically structured and distributed as follow:

- an African lineage (A),
- a north mediterranean and caucasian lineage (C)
- a west mediterranean lineage (M)

Theses lineages correspond to a racial and geographical division of the species which strongly confirm Ruttner's hypothesis on morphometrical data, excepted for the North African populations which are assigned to the A branch instead of the M branch. An hypothetical evolutionary scenario has been inferred from these data.

These conclusions are still partial and have been drawn from a limited set of colonies representing a dozen of the 24 subspecies. A much larger survey was necessary to get a better and sounder picture of the differentiation of the species. This is currently being performed with a simple and rapid test, combining PCR of the length polymorphism observed in the COI-COII intergenic region of the mitochondrial genome, followed by a restriction. This test has now been performed on more than 1500 colonies, confirming and extending previous conclusions on the evolution of *Apis mellifera*. Particularly a sub-structuration which had not been observed emerged in the African lineage. In the M lineage, the use of this test gave a good idea of the level of the mitochondrial introgression between lineages due to beekeeping.

PHYLOGENY AND EVOLUTION OF THE MITOCHONDRIAL CYTOCHROME OXIDASE II GENE IN COLLEMBOLA

Francesco Frati

Department of Evolutionary Biology, University of Siena, Italy.

The evolution of the mitochondrial COII gene is analysed in 11 morphological species of Collembola, belonging to four different genera (each one of a different family). The well-known A+T bias, common to all insect mitochondrial genes, is present, although it is lower than that observed in more derived orders, showing a trend to increasing A+T bias in the insect lineage. The number and distribution of variable sites, and the disappearance of the transition/transversion bias in between-genera comparisons suggest that sequences are saturated beyond the genus-level and that relevant corrections to genetic distance estimates should be applied. In addition, high levels of among-site rate variation are observed. The usefulness of the COII gene for reconstructing phylogenetic relationships within Collembola is examined at different taxonomic levels: populations, species, genera and families. Raw sequence divergence is very high at all taxonomic levels, always higher than that observed in other insects. Such high divergence levels may reflect a higher rate of evolution or, more probably, the old age of the groups. The performance of several distance-correction methods, incorporating nucleotide content and TI/TV bias, as well as among-site rate variation, is evaluated. The application of the more sophisticated correction methods reduces the resolution at the deeper nodes, and gives well supported phylogenetic reconstructions only within the genus *Isotomurus*. Distance-based and character-based phylogenetic reconstructions are compared. The lack of resolution at certain deeper nodes may reflect the inability of the COII gene to provide information at these levels or the occurrence of bursts of evolution in the differentiation of collembolan families.

NUMEROUS TRANSPOSED COPIES OF mtDNA IN *SITOBION* APHIDS - DISCOVERY AND POTENTIAL APPLICATIONS

P. Sunnucks and D.F. Hales

School of Biological Sciences, Macquarie University, Sydney, Australia.

PCR products obtained using primers for mtDNA cytochrome oxidase subunits I and II (mtDNA COI-II) were found to contain multiple haplotypes in three *Sitobion* species. We cloned and sequenced several copies from an individual of each species. Each individual aphid had one mtDNA copy of the sequence, and several other unique sequences shown to be non-mitochondrial by sequencing from purified mtDNA and Southern blotting experiments.

It is most likely that sections of mtDNA have been transposed on many separate occasions into *Sitobion* chromosomes. In these aphids, the phenomenon appears to occur at an almost unprecedented frequency, although it is seen infrequently or not at all in closely-related genera of aphids investigated.

MtDNA copied into the nucleus should be 'fossilized' in as much as it will cease to evolve like mtDNA, and will change at the nuclear pseudogene rate. Thus we believe that *Sitobion* aphids (and other species exhibiting mtDNA transposition) may be important for studying the comparative evolution of mtDNA and pseudogenes.

Our data highlight the need to confirm that putatively mitochondrial sequences obtained in phylogenetic and population genetic investigations are truly mitochondrial.

08-046

DIVERSIFICATION OF THE PHYTOPHAGOUS BEETLE SUPERFAMILY CHRYSOMELOIDEA : COEVOLUTION WRIT LARGE?

B. D. Farrell

Museum of Comparative Zoology, Harvard University, Cambridge, MA USA

Plant-feeding insects comprise nearly one-half of all insect species, yet nearly three quarters of insect herbivore diversity can be traced to just two origins of plant feeding: in the respective ancestors of the Lepidoptera and of the comparably diverse beetle clade "Phytophaga," which comprises the superfamilies Chrysomeloidea (leaf-, seed- and timber-beetles) and Curculionoidea (weevils). These beetle groups total some 128,000 species, or 10% of all described animal species on earth. The Phytophaga and Lepidoptera both arose in the Mesozoic, but these beetles have conserved much more of the apparent history of their affiliations with major hostgroups, and thus perhaps of their diversification, than have butterflies and moths. While most of these beetles are today affiliated with flowering plants, fossils document their first appearance in the Jurassic, before flowering plants arose. Indeed, the current affiliations of the morphologically most primitive subfamilies to which these fossils belong are with conifers and cycads (i.e., plants found in the same fossil beds), while groups of intermediate and advanced position occupy similarly positioned plants. In conjunction with the newest, DNA-based estimate of higher plant phylogeny and evidence from the substantial fossil record, analyses of over 100 complete 18S gene sequences and of morphological characters for these beetle subfamilies indicate that the current hostplant affiliations of these insects strongly reflects their ages of origin. Moreover, colonizations of newly-diversifying hostplant producers by these consumers are associated with much enhanced diversity, suggesting that innovations in lifestyle may spur herbivore radiation, with implications for assembly and diversity of insect/plant communities. It would also seem that such affiliations as are conserved over geological time and global space may, perhaps, be less reasonably ascribed to stabilizing selection than to paucity of genetic variation, bearing implications for extinction of herbivore groups whose hosts disappear.

INDUCED RESISTANCE IN PLANTS AGAINST GALL-FORMING INSECTS: ACTIVE DEFENSE OR LACK OF RECOGNITION? Stig Larsson, Carolyn Glynn & Solveig Höglund
Department of Entomology, Swedish University of Agricultural Sciences, Box 7044, 750 07 Uppsala, Sweden.

Gall-forming insects induce their host plants to supply them with shelter and food. A common feature of these organisms is that they manipulate their host by use of an intricate chemical signal system. If the signals fail, the gall maker is unable to initiate and maintain the necessary contact with the host plant; the gall is unsuccessful and the gall maker dies.

This study highlights the elements of close association between a willow, *Salix viminalis*, and the leaf-rolling cecidomyiid *Dasineura marginemtorquens*. Certain willow individuals have very few galls, due to high larval mortality, while plants growing beside suffer heavy gall midge infestation. The resistance is genetically based and is not of a constitutive nature. We suggest two alternative hypotheses as an explanation for the resistance in this system. First, analogous to what has been observed in many plant/microorganism interactions, the attacking larva may induce a signal that through a number of intermediate steps trigger the expression of defense genes. The result would be the active defense and a killed larva. Second, and specific to the situation in gall-forming organisms, the resistant genotype may not respond appropriately, from the insects point of view, and therefore the gall will not be induced. The result in this case would be that the larva starve to death.

The strong intraspecific variation in resistance that we have documented is unusual among herbivorous insects, and resembles more the situation for microorganisms. We suggest that the galling habit is responsible for this; the gall initiation is a very intricate process involving the transmission of specific chemical compounds from a rather sessile larva to the plant with opportunities for the plant to respond accordingly.

EVOLUTIONARY ECOLOGY OF ANT-PLANT SYMBIOSES:
INCLUDING ANTS IN THE ANALYSIS

Doyle McKEY and Loïc MEUNIER

Institut des Sciences de l'Evolution
Place Eugène Bataillon
34095-Montpellier-France

Centre d'Ecologie Fonctionnelle et Evolutive
CNRS, BP 5051
34033-Montpellier Cedex-France

Studies of the evolutionary ecology of symbiotic ant-plant mutualisms have usually been tacitly viewed from the plant's perspective, as if the biology of the ant partners could be reduced to the services (protection, feeding of the plant, etc.) provided to the plant. However, selection pressures acting on the ants, especially at the evolutionary outset of these symbioses, are complex and do not always act to reinforce mutualism. Recognition that the evolutionary interests of ants and plants in these symbioses are not entirely congruent opens up a number of new avenues for research, in which parasitism and evolutionary conflict appear as themes alongside mutualism.

These new lines of research concern (1) life history evolution of plant-ants in relation to coevolutionary interactions with plants; (2) how plants control investment in maintaining ants and the importance of this control for stability of the mutualism; (3) the evolution of parasitic strategies in these globally mutualistic interactions; and (4) conflict and cooperation in ant societies in relation to ant-plant coevolution.

EVIDENCE OF EVOLUTION OF FOOD-PLANT ASSOCIATIONS
SHOWN BY FAMILIES OF PHYTOPHAGOUS BRITISH INSECTS
AND MITES

L.K. Ward, A. Hackshaw¹, R.T. Clarke
Institute of Terrestrial Ecology, Furzebrook Research Station,
Wareham, England. - ¹ The Wolfson Institute, St Bartholomew's
Medical College, London, England

Data from food-plant records of British phytophagous insects and mites are used in a correspondence bi-plot analysis to demonstrate the interrelationships of all 6935 species of insects/ mites and about 2000 plants. These were arranged in a matrix of 186 insect/mite families and 117 plant families. The complex figure plotted from the first two axes of variation shows all insect and plant families together, and is used in a pattern analysis in which taxonomic and evolutionary relationships are shown to be important.

Insect and plant families in the analysis were ranked as 'primitive', intermediate or advanced. Sporne's index of advancement was used for dicots. The results indicate that many of the more advanced insect families are associated with more advanced plant families and visa versa. Advanced plant families are geologically younger, herbaceous and have more diverse secondary compounds, while primitive/more generalized plant families tend to be geologically older, woody and less diverse. Most of the phytophagous orders of insects/mites show some evidence of phylogenetic sequencing of family associations relating to the broad phylogenetic levels of plant groups. Elements of this same sequencing, summarized to the classes of plants, can be detected within insect families, although this may be obscured by switches to unrelated food-plants.

PATTERN AND PROCESS IN THE EVOLUTION OF INSECT-HOST
PLANT ASSOCIATIONS

Steph B.J. Menken, Peter Roessingh, Katja Hora & Eleanor Bremner¹
Institute for Systematics and Population Biology, University of
Amsterdam, the Netherlands - ¹ School of Biological Sciences, Univer-
sity of Bangor, Wales

Phylogenetic studies are increasing our understanding of the evolution of associations between plants and insect herbivores. Coevolution where reciprocal selection between interacting insects and plants is supposed to induce chemical diversification and resistance in plants and food specialization in insects appears to be less common than sequential evolution, i.e. the shift of insect herbivores onto pre-existing plant species.

Extreme host specificity is common in phytophagous insects. Hypotheses that assume that food specialists have selective advantages over generalists do not seem to provide a general explanation for the ubiquity of specialists. Specialists are probably committed to remain so, because they have little evolutionary opportunity to reverse the process due to genetically determined constraints on the evolution of their physiology or nervous system. The same constraints might result in phylogenetic conservatism, i.e. the frequent association of related insect herbivores with related plants. Current phylogenetic evidence, however, indicates that there is no intrinsic direction to the evolution of specialization.

Historical aspects of insect-host plant associations will be illustrated with the small ermine moth genus *Yponomeuta* (Lepidoptera, Yponomeutidae). Small ermine moths show an ancestral host association with the family Celastraceae. The genus seems to be committed to specialization per se rather than to a particular group of plants. Whatever host shift they have made in their evolutionary past (onto Rosaceae, Crassulaceae, and Salicaceae), they remain monophagous.

A scenario will be discussed in which sensitivity to dulcitol might have facilitated the shift from Celastraceae to the taxonomically unrelated and phytochemically dissimilar Rosaceae. Dulcitol is the major sugar alcohol in Celastraceae where it acts as a phagostimulant for larvae and possibly as an oviposition stimulant in adult females. It also occurs in low concentrations in species of the genus *Prunus* (Rosaceae), the very host plants of a number of *Yponomeuta* species.

GENE TREES, CHROMOSOME TREES, SPECIES TREES:
MOLECULAR PHYLOGENIES IN THE *ANOPHELES GAMBIAE*
COMPLEX.

A. Caccone
Dipartimento di Biologia II Università di Roma "Tor Vergata", Rome, Italy
and Department of Biology, Yale University, New Haven, Ct., USA.

The increasing number of studies using DNA sequences has produced a large number of papers where phylogenetic considerations of the relation of species are drawn based on single gene data. In this communication I would like to highlight the danger of confining molecular phylogenetic analysis to a single DNA region especially in recently diverged taxa. I will use the molecular studies carried out on the *Anopheles gambiae* complex as a case study to discuss this problem, taking advantage of the unusually detail knowledge of the biology of the group and of the chromosome location of the gene analyzed. Such information were essential in comprehending the conflict between different gene phylogenies.

The *Anopheles gambiae* complex includes the most efficient vectors of malaria in the world. The complex is confined to sub-Saharan Africa and consists of six closely-related sibling species. Until recently, the only information on the phylogenetic relationship among these species had been derived from chromosomal inversions. The use of these chromosomal variants relies on the assumption that existing inversions are monophyletic. Virtually all phylogenetic trees derived from molecular data have confirmed this assumption in other taxa. A recent exception was found in the *Anopheles gambiae* complex, where DNA sequence data from the mitochondria (mtDNA) and the nuclear rDNA intergenic spacer produced phylogenies in disagreement with the inversion tree. A simple explanation for this conflict could be that the inversions at study are not monophyletic. Because inversions protect genes within breakpoints from recombination, if inversions are monophyletic, then DNA sequences within inversions should reflect the evolutionary histories of the inversions. To test the monophyly of 3 important inversions in this group (X^{a9} , $2L^{a/+}$, and $3R^{a/+}$), DNA sequences within and on the breakpoints were analyzed from the six species included in the complex: *A. gambiae*, *A. arabiensis*, *A. merus*, *A. melas*, *A. quadriannulatus*, and *A. bwambae*.

08-052

PRELIMINARY STUDIES OF ECOLOGICAL AND GENETIC ISOLATION OF *ANOPHELES BWAMBAE* OF THE GAMBIAE COMPLEX (DIPTERA: CULICIDAE)

R.E. Harbach, M. Charalambous

Department of Entomology, The Natural History Museum, London, England

Studies were conducted in the vicinity of the geothermal springs in Bwamba County, Uganda to assess the degree of ecological and genetic isolation between three species of the Gambiae Complex: *An. bwambae*, a species known only from the geothermal springs environment, *An. gambiae* and *An. arabiensis*. The results of DNA identification and oviposition tests indicate that the larvae of *An. bwambae* and *An. gambiae* may occupy the same habitats in drainage water derived from the springs. Variability of adult and larval morphology and isozyme polymorphisms at the ODH and SOD loci show evidence of incomplete divergence between these two species, while the use of DNA primers for species identification indicate that they are well segregated. *Anopheles bwambae* and *An. arabiensis* appear to be essentially parapatric.

08-053

A MOLECULAR PHYLOGENY FOR THE *DROSOPHILA MELANOGASTER* SUBGROUP.

L. Nigro¹, A. Caccone^{2,3}, E. N. Moriyama², M. Gleason² & R. Powell²
¹Università di Padova Italy, ²Yale University New Haven, USA, ³Università di Roma, II "Tor Vergata" Rome, Italy.

Drosophila melanogaster belongs to a closely-related group of eight species collectively known as the *melanogaster* subgroup; all are native to sub-Saharan Africa and Islands off the east coast Africa. The phylogenetic relationships of most species in this subgroup have been well-documented; however, the three most closely related species, *D. simulans*, *D. sechellia*, and *D. mauritiana*, have remained problematic from a phylogenetic standpoint as no data set has unambiguously resolved them. We present new DNA sequence data on the *nullo* gene and combine it with all available DNA sequence data; the total data set are 11 genes and the ITS of rDNA. A methodological problem had to be overcome as several of the genes had considerable information on intra-specific polymorphisms. We adopted the strategy of eliminating all polymorphic sites as they represent either ancient polymorphisms which could lead to gene tree/species tree problems, or are autapomorphies and thus contain no phylogenetic information. We have also re-analyzed our previous DNA-DNA hybridization data with a bootstrap procedure. The combined sequence data set and the DNA-DNA hybridization data strongly support the sister status of the two island species, *D. sechellia* and *D. mauritiana*. This at least partially resolves what had been a paradox of parallel evolution in these two species.

08-054

PHYLOGENY OF *Dolichopoda* CAVE CRICKET SPECIES BASED ON SATELLITE DNA SEQUENCES

F. VENANZETTI¹, L. BACHMANN² & V. SBORDONI¹

¹ Department of Biology, University of Rome "Tor Vergata"

² Department of Population Genetics University of Tübingen

Dolichopoda cave crickets are currently the object of extensive research in our laboratory with the aim to investigate evolutionary relationships among populations and species by means of several markers with different informational value in respect of phylogeny and adaptation. In recent years we are investigating tandemly repeated satellite DNA a class of non-coding DNA supposed to be fast evolving and selectively neutral. We have isolated and characterized three families of satellite DNA, two of which are species specifically amplified only in one species of *Dolichopoda* while the third one is widely distributed throughout the entire genus. One typical feature of highly repeated DNA families, common to all satellite DNAs so far analysed is its high intraspecific sequence homogeneity contrasting high interspecific diversity. Sequence data of each satellite DNA family from different *Dolichopoda* populations were used to generate trees: as expected, sequences derived from conspecific populations cannot be discriminated. However, sequence data from the satellite sequences spread over the whole *Dolichopoda* genus generate trees showing homogeneous clusters of sequences, which are consistent with the specific rank of populations: species can clearly be discriminated while conspecific populations are not. The phylogenetic relationships inferred from this family of sequences are in agreement with those derived from other molecular markers such as allozyme polymorphisms, DNA-DNA hybridization data and mitochondrial RFLPs; this suggests a role for satellite DNA as a marker for cladogenetic events.

08-055

ENZYMATIC ANALYSIS OF THE AZOREAN, PORTUGUESE MAINLAND AND CANADIAN POPULATIONS OF *MYTHIMNA UNIPUNCTA* (HAWORTH) (LEP., NOCTUIDAE)

V. Vieira, J. Tavares & B. Pintureau¹

Departamento de Biologia, Universidade dos Açores, Ponta Delgada, Portugal

¹ INSA de Lyon, Biologie, Villeurbanne, France

Polyacrylamide gel electrophoresis was used to evaluate the genetic population structure of the armyworm, *Mythimna unipuncta* (Haworth) (Lepidoptera: Noctuidae), an agricultural pest in the Azores archipelago. Electrophoretic analysis of four enzyme systems (aldehyde oxidase, esterase, phosphoglucose mutase, phosphoglucose isomerase) was performed on six populations from azorean islands (Santa Maria, São Miguel, Terceira, Pico, Faial, Flores), which were compared with those for the Portugal mainland (Europe) and Canada (North America). The band patterns were described, compared and interpreted from both genetic and evolutionary point of views.

08-057

USE OF RANDOM AMPLIFIED POLYMORPHIC DNA POLYMERASE CHAIN REACTION (RAPD-PCR) TO DETECT DNA POLYMORPHISMS IN *Dacus oleae* (DIPTERA: TEPHRITIDAE).

M.D. Ochando, C. Callejas, P. Roda, A. Reyes.

Dpto. de Genética, Facultad de CC. Biológicas, Universidad Complutense, 28040-Madrid, Spain.

The polymerase chain reaction (PCR) was used to generate random amplified polymorphic DNA (RAPD) from olive flies DNA samples in order to assess the degree of polymorphism within the genus and to investigate if this approach was suitable for genetic studies of this species.

Genomic DNA was extracted from 20 individual *Dacus oleae* flies from two geographic populations and amplified in PCR reactions using single primers of arbitrary sequence. Sixteen different oligonucleotide primers (C1, C2, C3, C4, C5, C6, C7, C8, C10, C11, C14, C15, C16, C18, C19, C20, Operon Technologies) yielded clear and reproducible bands corresponding to amplified products and separable by agarose gel electrophoresis. A total of 215 bands were obtained. Of these, 155 bands were variables, and 26 were present in only one of the populations. The intra and interpopulational mean values of Jaccard (0.6727 and 0.6682, respectively) were not statistically different. The results are discussed in relation to the suitability of the technique in population genetic studies of agricultural pests.

08-056

USE OF MOLECULAR MARKERS FOR RACE DIFFERENTIATION OF THE GYPSY MOTH *LYMANTRIA DISPAR* L.

A. Reineke, C.P.W. Zebitz

Department of Entomology, Institute of Phytomedicine, University of Hohenheim, Stuttgart, Germany

The first observation of flying gypsy moth females - so far known as being characteristic only for Asian gypsy moth populations - in Southwest Germany in 1993 supported the conclusion that the Asian race of the gypsy moth has become established in Germany. Differentiation by "traditional" morphological characteristics is not successful in clearly distinguishing both the European and Asian race of the gypsy moth. The use of various molecular markers based on the polymerase chain reaction (PCR) resulted in characteristic DNA fingerprints which could be used for positive identification of the different races in Southwest Germany. Additional studies indicated that gypsy moth females from different German populations are indeed capable of sustained flight, but that this ability is strongly correlated to their geographic origin. The interpretation of this behavior is discussed on the basis of the molecular genetic approach.

08-058

RANDOM AMPLIFIED POLYMORPHIC DNA OF SCREWORM FLY POPULATIONS (DIPTERA: CALLIPHORIDAE) FROM BRAZIL.

M. E. Infante and A. M. L. Azeredo-Espin

Departamento de Genética e Evolução e Centro de Biologia Molecular e Engenharia Genética-CBMEG, Universidade Estadual de Campinas, Campinas, São Paulo, Brasil

The screwworm fly, *Cochliomyia hominivorax* (Coquerel, 1859) one of the most important pests causing invasive myiasis in warm-blooded vertebrates in Brazil. Several studies at molecular level have been conducted to analyze the genetic variation in natural populations of this species. In this work we have attempted to characterize the polymorphism of *C. hominivorax* using genomic markers.

The PCR based technique involving the random amplification of polymorphic DNA (RAPD) produces diagnostic DNA fragments, which can be used to characterize and differentiate insect populations. This technique was optimized and used to study the genomic variability among four *C. hominivorax* populations in São Paulo State (Adamantina, Amparo, Botucatu and Valinhos). Genomic DNA of *C. hominivorax* was tested using eleven different DNA concentrations for amplification conditions optimization. Reproducible bands were amplified until 100 µg of DNA.

RAPD fingerprints presented high variation for ten primers used (Operon Technologies, Alameda, CA), giving 298 polymorphic bands out of 389, ranging from 520 to 3000 bp in size. The average number of polymorphic bands was 7.5 per primer. The OPB-02, OPB-06 and OPB-09 primers were able to detect a high number of polymorphic bands in all *C. hominivorax* populations.

An estimate of within and between population dissimilarity based on the dissimilarity index (*d*) was calculated and can improve discrimination in *C. hominivorax* populations. The within population dissimilarity values ranged from 9.5% (Valinhos) to 11.7% (Botucatu), and the between population dissimilarity values ranged from 6.9% (Amparo v/s Valinhos) to 10.6% (Adamantina v/s Botucatu).

This genomic polymorphism detected with RAPD-PCR in populations of *C. hominivorax* has indicated that this species has a high level of variation in tropical habitats, with differentiation of populations, as was suggested by the mtDNA analysis.

Financial Support: CNPq, FAPESP, FINEP/PADCT.

08-059

KARYOTYPIC STRUCTURE TRANSFORMATION OF
SIBERIAN MALARIA MOSQUITOES (DIPTERA:
CULICIDAE) AS A RESULT OF GLOBAL WARMING

M.I. Gordeev

Research Institute of Biology and Biophysics,
Tomsk State University, Tomsk, Russia

Historically, ecological diversification and occupation of new niches during the adaptive radiation of Palearctic mosquito species depended on 2 principal selection strategies. Apparently, K-strategy was the initial one in the group of *Anopheles maculipennis* sibling species, which includes *An. messeae*. Expansion of *An. messeae* to the northeast of the Palearctic was associated with changes in selection strategy and origination of "northern" chromosomal inversions. Mosquitoes with combinations of such inversions are r-strategists. Nowadays there is a strong trend towards frequencies increasing of "southern" karyotypes in the populations of the West Siberia as the result of global warming. Exclusion of r-strategists gives rise to a new system of biotic connections in the mosquito breeding places.

08-061

METAPOPULATION STRUCTURE IN *APHIS GOSSYPHII* IN
GREENHOUSES: EVIDENCE FROM MOLECULAR MARKERS

F. Vanlerberghe-Masutti, E. Mühlberger, P. Chavigny and L. Lapchin

Equipe de Biologie des Populations, Laboratoire de Biologie des
Invertébrés, Institut National de la Recherche Agronomique, Antibes,
France.

Random amplified polymorphic DNA markers and allele variation at microsatellite loci were used to study the genetic diversity of populations of aphids, *Aphis gossypii*. Aphid clones were collected in two greenhouses (50 km apart) on several host plants and outdoor surrounding plants, two times during the plant infestation process (founding and culminating) and over three successive years. Beside the genetic polymorphism detected within each sample, factorial analyses revealed a statistically significant variation in the population genetic structures in relation to year, site, host plant and time of sampling. The results provide evidence that local populations of aphids are not persisting in each site from year to year but experience frequent extinction recolonization processes. Moreover, there was an increase of genetic polymorphism among aphid clones sampled in one greenhouse during the plant infestation process. The most likely explanation for this variability is to consider that dispersion of aphids is occurring among local populations. The results suggest that the long time persistence of *Aphis gossypii* populations can be explained by the metapopulation model.

08-060

GENE FLOW AND THE GEOGRAPHIC STRUCTURE OF
NATURAL POPULATIONS OF *CERATITIS CAPITATA*.

A.R. Malacrida¹, C.R. Guglielmino^{2,3}, F. Marinoni¹, C. Torti¹, G. Damiani⁴, G. Gasperi^{1,5}.¹Department of Animal Biology, University of Pavia, Pavia, Italy²Department of Genetics & Microbiology, University of Pavia, Pavia, Italy³Institute of Genetics & Evolutionary Biology, CNR, Pavia, Italy⁴Institute for the Exploitation of Animal Germoplasm, CNR, Milan, Italy⁵Institute of Zoology, University of Sassari, Sassari, Sardinia, Italy

Five populations from African region (Kenya, Reunion, Morocco, Canary, Madeira), nine Mediterranean (Spagna, Sardinia, Procida, North Italy, Libya, Israel, Creta, Chios, Greece) and three from the New World (Hawaii, Guatemala, Australia) for a total of 82 samples, were examined by electrophoresis for genetic variability at 26 enzyme loci (MLEE approach).

Wright's F_{ST} , Slatkin's estimates, together with tree representations have been used to compare the African populations with the derived ones. Parameters using gene frequencies (F_{ST} , D , N_m) indicate the presence of substantial geographic heterogeneity correlated with the dispersion of medfly from its source area (Sub-saharian Africa) to the periphery. Significant gene flow estimates between African and the derived populations support the hypothesis of a recent colonization of *C. capitata*.

These results are significantly correlated with those derived from DNA data both with RAPDs (Baruffi et al., 1995, *Heredity*, 74: 425-437) and scDNA polymorphism (Gomulski et al., accompanying poster).

08-062

Study of the biology and distribution
of the Russian wheat aphid. *Diuraphis*
noxia(Mordvilko)(Hom-Aphididae) in
Tehran province.

Gh. Reza. Rassoulia and L. Doulati.

Our investigations on the biology of Russian wheat
aphid in green house and field conditions resulted:

- 1) The average time to complete the nymph stage was 7.5 days.
- 2) The average of pre reproductive, reproductive, postreproductive periods and total longevity were 1,42.88, 11.63 and 63 days respectively.
- 3) The average number of nymphs produced by each parthenogenetic female was 72.12.
- 4) At the field condition, the average time required to complete nymphal stage was, 19.71. the average for pre reproductive, reproductive, post reproductive periods and total longevity was 2.43, 49, 43, 87.43 days respectively. average nymph for each aphid was 76.80. our studies indicated, Russian wheat aphid over winters on some grasses and cereal hosts as parthenogenetic female. The investigations showed that, *D. noxia* was distributed at many areas of Tehran province as Varamin, Damavand Talegan, Shahriar and Ghazin.

08-063

DISCRIMINATION OF DIFFERENT CLONES OF *APHIS GOSSYPHII* GLOVER (HOMOPTERA: APHIDIDAE) BY RAPD-PCR

S. Komazaki, Mh. Osakabe

Akitsu Branch, Fruit Tree Research Station, MAFF, Akitsu, Hiroshima, Japan

Total DNA was extracted and purified from 5 adult virginoparous females of *Aphis gossypii* clones cultured in the laboratory. DNA was amplified in the 20 μ L PCR buffer with 0.5 μ L of template DNA (1 ng / μ L), 1 μ L of primer (20 pM / μ L) and 1 μ L of Taq DNA polymerase. Five aphid clones differing in life-cycle and six clones differing in insecticide resistance were used for experiments. These clones are tested by RAPD with each of 92 random primers; Operon's ten- or Wako's twelve-nucleotide oligomer. Amplification reactions were carried out for 45 cycles of 1 min at 92°C, 1 min at 35°C and 2 min at 72°C. Several fragments of DNA were amplified in each clone with each primer. Banding patterns generated from some primers appeared to distinguish different clones having different biological traits. These primers shall be tested for other clones to assure the general applicability.

08-065

INTRASPECIFIC VARIABILITY IN HOST PLANT ADAPTATION OF THE GREENBUG, *SCHIZAPHIS GRAMINUM* ROND. (HOMOPTERA: APHIDIDAE)

E.E.Radchenko

N.I.Vavilov Institute of Plant Industry (VIR), St.Petersburg, Russia

An analysis of greenbug clones, sampled during 1993-1995 from sorghum fields at the Cuban'Exp. Sta. of VIR (Krasnodarskii Krai), revealed a wide variability in host plant exploitation by the pest. It has been possible to classify the aphid into at least 6 phenotypes which differ in their ability to destroy sorghum lines with specific major genes for resistance. We tested the Sarvasi cultivar, used widely in breeding programs, the donors of resistance employed in the USA (KS-30, Capbam, PI 264453) and the new resistance donors (k-924, k-1362, k-9436). Sarvasi and the lines with genes identified in the USA and which Russian greenbug populations have never met, are susceptible. However, we have found some clones avirulent to Sarvasi, Capbam and PI 264453 for 3 years. Most of the clones were avirulent to the gene in k-9436 and two clones were virulent to the genes in k-9436 and k-1362 in 1993 only. The sample k-924 is highly resistant to all the clones. The lines with noneffective genes have a low level of resistance to all virulent clones. This may be a result of "residual" effect of oligogenes or an effect of minor genes. The population diversity is attained by mutations, recombinations (the main greenbug gene pool in Russia is holocyclic) and assimilation of immigrants. This diversity is a base for aphid adaptation to new resistant sources. Further studies are in progress to develop a sorghum differential set.

08-064

ROUTES TO SOCIALITY IN *PEMPHIGUS* (HEMIPTERA: PEMPHIGIDAE) - MORPHOMETRIC CLUES.J.A. Whitfield, N. MacLeod¹

Department of Zoology, University of Cambridge, Cambridge, UK - 1 Department of Palaeontology, Natural History Museum, London, UK.

British species of the gall forming aphid genus *Pemphigus* display a wide diversity of life history and behavioural traits. In particular, *Pemphigus spyrothecae* Pass. is unique in its loss of host alternation and its production of dimorphic first instars in the third gall generation, including an altruistic defensive morph.

Morphometric analysis of *Pemphigus* first instars shows that *P. spyrothecae* "soldiers" are extremely similar to the first instars of the second gall generation found in all examined gall-forming *Pemphigus*, while it is thought that the "non-soldiers" are equivalent to the monomorphic secondary host generations of host alternating species. A major evolutionary innovation, then, in *P. spyrothecae* is the production by apterac of second gall generation "soldier" type first instars in the third gall generation.

Although the gall generations of several *Pemphigus* species show attacking behaviour, *P. spyrothecae* shows additional morphological adaptations that seem to suit it to a soldier role. These include relatively thicker hind femurs and broader, more hooked claws on the hind legs - the limbs most important in attacking behaviour - than host-alternating species.

This combination of behavioural, life cycle and morphometric data points to the sequence of evolutionary events in *Pemphigus* being the evolution of attacking behaviour in a number of species, followed in *P. spyrothecae* by the loss of host alternation, the production of soldiers in the third gall generation and morphological specialisation of soldier type first instars.

08-066

MORPHOMETRIC STUDY OF *DROSOPHILA SERIDO* POPULATIONS FROM CENTRAL AND SOUTHERN REGIONS OF BRAZIL.S. G. Monteiro, F. M. Sene¹

Departamento de Biologia, Universidade Federal do Maranhão, São Luís, Brazil -1 Departamento de Genética, Universidade de São Paulo, Ribeirão Preto, Brazil.

Drosophila serido is an endemic species in South America. Analysis of various markers has shown that this species is excellent material for studies on evolution, due its considerable diversity. Aedeagus morphology is the main feature used to separate species and to identify populations that are in a differentiation process. Aedeagus morphology was analyzed in 18 populations of *D. serido*, from central and southern regions of Brazil. Multivariate analyses of the data confirmed the existence of two distinct groups of aedeagi, named B and D. Measurements of the two superior curvatures of the aedeagus best discriminate the two types. There was a relationship between types of aedeagus and species of cactus: type B is associated with *Philosocereus machrisii*, found in high altitude cerrado, while type D is associated with *Cereus hildemannianus*, normally found along river valleys. Analysis of populations of each type has show that populations found on hills, classified as type B, are heterogeneous while those found along the rivers (type D) are more homogeneous. This implies geographical isolation of type B populations and considerable gene flow between type D populations, which would affect differentiation and consequently speciation.

08-067

MORPHOLOGICAL AND GENE-ENZYME VARIABILITY OF SYMPATRIC POPULATIONS OF THE SPECIES *Aedes caspius* (Pallas, 1771) and *Aedes dorsalis* (Meigen, 1830) (Diptera: Culicidae)

Vesna Milankov, Ljiljana Vapa, Dragana Radović, A. Vujić

Institute of Biology, University of Novi Sad, 21000 Novi Sad, Yugoslavia

Genetic variability of sympatric populations of the species *Aedes caspius* and *Aedes dorsalis*, from the soil lake Rusanda (Yugoslavia), performed by analyzing morphometric characters and gene-enzyme variability was studied. Morphological characters have been analyzed on the IV instar larvae. Statistically significant differences were observed between the mean values of the number of pecten teeth and the siphon-length index (but not in number of teeth in the siphon tuft, siphon index, area and circumference of the siphon).

By the PAG electrophoresis eight enzyme controlled by nine loci: *Gpd-2*, *Gpi*, *Me-2*, *Idh-2*, *Hbd*, *Odh*, *Est-1*, *Est-5* and *Pgm* were analysed. Genetic variability of *Ae. caspius* showed: 33.3% polymorphic loci, 3.7 mean number of alleles per locus, and 30.5% expected mean heterozygosity and that of *Ae. dorsalis* 33.3% polymorphic loci, 3 mean number of alleles per locus, and 30.7% expected mean heterozygosity. The genetic distance between these two species was 0.557.

08-069

THE USE OF MORPHOMETRICS OF MALE GENITALIA AND FEMALE WING VENATION IN THE IDENTIFICATION OF *CULEX PIPIENS* L. COMPLEX IN IRAQ

Z. H. Mohsen, M. Al-Saady¹

Arab Pest Control Center, PO Box 926270, Amman 11110, Jordan - ¹Biological Research Center, Jadiriya, PO Box 2371, Baghdad, Iraq

The two mosquitoes, *Culex quinquefasciatus* say (Baghdad strain) and *Culex pipiens molestus* Forskal (Mosul strain) could be differentiated based on the characters of male genitalia and female wing venation. The D/V ratios for *Cx. quinquefasciatus* and *Cx. p. molestus* were 0.337 and 1.434 and the DV/D ratios were 1.054 and -1.137 respectively on average. The R-cell and M-cell ratios of the right wing venation of *Cx. quinquefasciatus* and *Cx. p. molestus* were 303.08 and 347.66 (R-cell) and 185.02 and 170.17 (M-cell) respectively. The mean values of M- and R-cell ratios were significantly different between the two mosquito species with a marginal error.

08-068

EVIDENCE FOR PHENOTYPIC SEXUAL SELECTION OF A MALE GENITALIC CHARACTER IN THE SEEDBUG *LYGAEUS SIMULANS* (HETEROPTERA: LYGAEIDAE)

A. Tadler, H. Nemeschkal, G. Pass

Institut für Zoologie der Universität Wien, Vienna, Austria

The female choice theory of genitalia (Eberhard 1985) predicts the existence of phenotypic sexual selection of male genitalia mediated by female choice. To evaluate this, a selection experiment was conducted with 48 laboratory bred virgin males of *Lygaeus simulans* Deckert. Each male had the opportunity to copulate with three virgin females. Mating success was judged by occurrence of sperm in the female spermatheca 24h after copulation.

Only 60% of the copulations were successful. A Lande-Arnold analysis (multiple regression of mating success against genitalic and non-genitalic male characters) indicates direct stabilising selection on a morphological genitalic character of males (length of processus gonopori).

08-070

REDUCED VARIATION IN *DROSOPHILA SIMULANS* MITOCHONDRIAL DNA

J. William O. Ballard^{1,2}, Joy Hatzidakis², Timothy L. Karr³ and Martin Kreitman²

Department of Zoology, The Field Museum, Chicago, USA - 1
Department of Ecology and Evolution, University of Chicago, Chicago, USA - 2. Department of Organismal Biology and Anatomy, University of Chicago, USA - 3.

Two recent studies of DNA sequence polymorphism in *Drosophila simulans* mitochondrial genes found evidence for reduced variation, indicating a recent hitchhiking event accompanying natural selection. To test whether the lack of variation in *D. simulans* mtDNA is associated with a current *Wolbachia* infection we sequenced three regions of the mitochondrial genome in 36 uninfected and four infected wild-caught isofemale lines from a single population in Lantana, Florida. Mitochondrial variability is significantly reduced in both infected and the pooled sample of infected and uninfected flies compared to a noncoding region of the nuclear-encoded gene, *Adh*^r. The loss of mitochondrial variation must have occurred prior to the current *Wolbachia* infection, possibly by genetic hitchhiking accompanying selection at linked sites. Alternative scenarios to explain this unexpected result will be discussed.

08-071

WOLBACHIA INFECTION AND CYTOPLASMIC INCOMPATIBILITY IN DROSOPHILA SPECIES

K. Bourtzis, A. Nirgianaki¹, C. Savakis¹
Institute of Molecular Biology and Biotechnology, Foundation for Research and Technology Hellas, Heraklion, Crete, Greece
¹ Division of Medical Sciences, Medical School, University of Crete, Heraklion, Crete, Greece

Wolbachia, a maternally inherited microorganism, was first described in the *Culex pipiens* complex and it has since been associated with cytoplasmic incompatibility, thelytoky and feminization phenomena in a variety of arthropods. Cytoplasmic incompatibility in insects results in either embryo mortality or production of all-male progeny from a cross between an infected male and an uninfected female and it has been reported in diverse insect taxa.

In the present study, forty-one stocks from thirty different *Drosophila* species were surveyed for *Wolbachia* infection using PCR amplification of *dnaA* and 16S rDNA sequences. *D. sechellia* and two strains of *D. auraria* were found to be infected and were tested for the expression of cytoplasmic incompatibility, along with *D. ananassae* and six strains of *D. melanogaster*, which are already known to be infected. *D. ananassae* and *D. melanogaster* show levels of incompatibility up to 25%, while *D. auraria* and *D. sechellia* exhibit levels of egg mortality higher than 60%. A dot-blot assay using the *dnaA* sequence as probe was developed to assess the infection levels in single flies. The stocks examined were classified into two groups, depending on the levels of infection relative to the degree of cytoplasmic incompatibility exhibited. One group, containing *D. simulans* Hawaii, *D. sechellia*, and *D. auraria*, exhibits high levels of cytoplasmic incompatibility relative to levels of infection; all the other species and *D. simulans* Riverside belong to the other group, which exhibits significantly lower levels for cytoplasmic incompatibility relative to infection levels. A positive correlation between bacterial density and cytoplasmic incompatibility was observed within each of the two groups. These data show that, in addition to bacterial density, bacterial and/or host factors affect the expression of cytoplasmic incompatibility.

08-073

THE HYBRID ZONE BETWEEN TWO SUBSPECIES OF CORN ROOTWORM BEETLES, *DIABROTICA VIRGIFERA VIRGIFERA* AND *D.V. ZEA*, IS INFLUENCED BY A *WOLBACHIA* INFECTION.

R. Giordano, J.J. Jackson*, and H.M. Robertson
Department of Entomology, University of Illinois Urbana-Champaign, Urbana, IL 61801
* Northern Grain Insects Research Laboratory, USDA-ARS, Brookings, SD 57006

We report that *Wolbachia* bacteria are the cause of the unidirectional reproductive barrier observed between the subspecies of the chrysomelid beetles *Diabrotica v. virgifera* and *D. v. zea*, two major pests of maize commonly known as the Western and Mexican corn rootworms. Previous work on these Chrysomelid beetles has revealed that few eggs hatch from the cross of *D. v. virgifera* males with *D. v. zea* females. Using PCR primers specific to the 16S ribosomal RNA of *Wolbachia*, populations of *D. v. virgifera* were sampled throughout the range of this subspecies and were consistently found to be infected with *Wolbachia*, but *D. v. zea* populations tested were not infected. Treatment of a *D. v. virgifera* stock with tetracycline to remove the *Wolbachia* removed the mating incompatibility with *D. v. zea* females. We infer that the present population of *D. v. virgifera* acquired the *Wolbachia* infection in Mexico, its putative site of origin shared with *D. v. zea*, prior to spreading to its present range, and that *D. v. zea* may be the parental population. The subspecies status of *D. v. virgifera* and *D. v. zea* is largely attributed not to intrinsic genetic differences but on the basis of infection with an endosymbiont. Given the relatively common presence of *Wolbachia* in insects it is likely that other insect hybrid zones may be in part determined by an infection with this bacterium.

08-072

SPATIAL AND TEMPORAL DYNAMICS OF INFECTION WITH *WOLBACHIA*, CYTOPLASMIC INCOMPATIBILITY MICROORGANISMS, IN NATURAL POPULATIONS OF SMALL BROWN PLANTHOPPER, *LAODELPHAX STRIATELLUS* (HOMOPTERA: DELPHACIDAE), IN CENTRAL JAPAN

S. Hoshizaki
Department of Agricultural and Environmental Biology, Graduate School of Agriculture and Agricultural Life Sciences, The University of Tokyo, Tokyo, Japan

Cytoplasmic incompatibility (CI) is caused in various insects by intracellular infection with rickettsia-like microorganisms of the genus *Wolbachia*. The theoretical viewpoints expect *Wolbachia* infection to spread in host population due to unidirectional CI, although information on spatial and temporal dynamics of *Wolbachia* infection in natural insect population is limited except for *Drosophila simulans*. In Japan, *Laodelphax striatellus* shows unidirectional CI between northeastern and southwestern populations. In 1994, nine natural populations of *L. striatellus* collected from central Japan were analysed for *Wolbachia* infection by the polymerase chain reaction (PCR) using primers specific to *Wolbachia* 16S ribosomal DNA. The infection rates appeared to show clinal decrease from southeast to northeast. Comparison with a previous study suggested that in some populations of *L. striatellus* the infection property had changed from the uninfected to the infected. Based on such geographic and temporal pattern, it was concluded that *Wolbachia* infection in *L. striatellus* populations have spread northeasterly during 1982-1994. More detailed geographic pattern of *Wolbachia* infection polymorphism will be discussed and temporal dynamics of infection will be inferred based on the results of PCR assay for samples collected in 1995.

08-074

WOLBACHIA INFECTIONS IN THE FLOUR BEETLE *TRIBOLIUM CONFUSUM*: EVIDENCE FOR A SINGLE AND COMMON CYTOTYPE AMONG STRAINS

R.F. Fialho and L. Stevens
Department of Biology, University of Vermont, Burlington, VT USA

The flour beetle *Tribolium confusum* is one of many insect species known to harbor a rickettsial symbiont (*Wolbachia*) that causes cytoplasmic incompatibility in its hosts. Despite its maternal pattern of transmission, parasite-host phylogenies indicate *Wolbachia* has been transferred horizontally, even across distantly related host species. In addition, some insects are also known to harbor infection with two different strains of *Wolbachia*. This is of evolutionary interest as it raises questions of how these double infections can be acquired and maintained.

We surveyed 12 geographical strains of *T. confusum* for infection using *Wolbachia*-specific PCR primers. We also tested 8 infected strains for differences in their compatibility types by single-pair matings between infected individuals. The results show that the strains tested are infected with a common incompatibility type. Finally, we surveyed all infected strains for double *Wolbachia* infections by using specific PCR primers and diagnostic PCRd analysis. The molecular data show that all infected strains harbor a single and common cytotype, which correlates with the results of mating tests.

08-075

GENETIC VARIABILITY OF THE RESISTANCE TO HIGH TEMPERATURES AND ANTIBIOTICS IN A HOST-SYMBIOTE SYSTEM

B. Pintureau, L. Chapelle
INSA, UA INRA 203 (Biologie appliquée), Villeurbanne, France

Several *Trichogramma* species (Hymenoptera: Trichogrammatidae) live in symbiosis with intracellular microorganisms belonging to the genus *Wolbachia*, which induce a thelytokous parthenogenetic reproduction. *Trichogramma cordubensis* Vargas & Cabello, a species living in southern Europe and northern Africa, is entirely infested in the wild. However, in summer, a natural thermotherapy can restore a bisexual reproduction. We verified the existence of a genetic variability of the resistance to high temperature (30°C) and to minocycline (10% in solution) in a host-symbiote system (*T. cordubensis*-*W. trichogrammae* Louis & Pintureau) from Azores. Treatments (rearing at 30°C, imagos supplied with diluted honey + minocycline) were applied for 3 generations (G1-G3). *Trichogramma* pairs (20 at 30°C and 28 with minocycline) were constituted at the G3 and supplied with *Ephestia kuehniella* Zeller (Lepidoptera: Pyralidae) eggs as hosts. Offspring of the obtained lines was isolated, and 4 to 18 pairs were constituted in each line and supplied with hosts. Sex ratios (male and intersex* percentages) were calculated in offspring of these pairs. As usually done to estimate genetic variability, we compared the within- and between-line variances (sex ratios were 2 arc sin $\sqrt{}$ transformed) by one-way analyses of variance (anova). Results of the analyses:

Anova	30°C			Minocycline		
	% males	% intersexes	% males + intersexes	% males	% intersexes	% males + intersexes
F	3,829	1,512	4,087	3,286	3,144	3,272
p	0,0001	0,0904	0,0001	0,0001	0,0001	0,0001

Thelytoky is more or less persistent, i.e. "Individuals" (1 *Trichogramma* + n *Wolbachia*) show a more or less important resistance to high temperatures and antibiotics. A part of this variability has a genetic origin but we cannot know if responsible genes belong to the host genome, the symbiote genome or both. Thus, the bisexual reproduction can reappear more or less easily according to individuals, and an adaptative selection is possible.

* Intersexes or gynandromorphs: individuals showing female genitalia and 1 or 2 male antennae, appearing not only after heat or antibiotic treatments but also spontaneously in the thelytokous strains.

08-077

PARASITOID MEDIATED HORIZONTAL TRANSFER OF *WOLBACHIA* BETWEEN PARASITOID HOSTS, AND BETWEEN HOST AND PARASITOID.

R.Butcher, W.Whitfield & S.Hubbard;
Department of Biological Sciences, Dundee University, Scotland.

Wolbachia are a closely related group of intracellular α -proteobacteria which are widely distributed throughout the arthropod lineages and which exhibit vertical transmission (maternal) to successive host generations. the ability of these parasites to alter the host physiology (e.g. cytoplasmic incompatibility, parthenogenesis, feminisation and altered host immunity) has centred interest around the role of these symbionts in speciation or biological control. Molecular phylogenetic analysis of *Wolbachia* evolution and divergence relative to its arthropod hosts, along with recent observations in the spread of this parasite, strongly infers a role for horizontal transfer within and between arthropod species, at least in an evolutionary time scale.

Here we present experiments utilising both *Drosophila* and *Lepidoptera*-parasitoid systems, that strongly support a role for insect parasitoids as vectors for the horizontal transfer of *Wolbachia* between the parasitoid prey species, and also between the parasitoid and its prey, within an ecological time scale. However, parasitoid mediated horizontal transfer of *Wolbachia* displays a strong co-dependency upon the parasitoid's prey species and the *Wolbachia* isolate. The implications of this specificity of efficiency of horizontal transfer for host and parasite co-evolution and speciation will be discussed in the light of this data.

08-076

HOST AND PARASITE CO-SPECIFIC INTERACTIONS IN *WOLBACHIA*-MEDIATED INDUCTION OF CYTOPLASMIC INCOMPATIBILITY AND PARTHENOGENESIS IN *DROSOPHILA* HOSTS.

R.Butcher, W.Whitfield & S.Hubbard;
Department of Biological Sciences, Dundee University, Scotland.

Wolbachia are a closely related group of intracellular α -proteobacteria that induce altered host (arthropod) physiology. Following the isolation of *Wolbachia* free of host cell organelles and transfecting into different *Drosophila* hosts, the ability of *Wolbachia* to induce uni- or bidirectional cytoplasmic incompatibility (CI) or parthenogenesis was found to be dependent upon both the *Wolbachia* isolate and the *Drosophila* host utilised. Additionally, the same *Wolbachia* isolate give different effects in different geographical isolates of the same *Drosophila* species, as well as in different species. Moreover, the differences in degree and type of altered host physiology induced in the transfectants varied markedly both within and between the *Drosophila* groups studied (melanogaster, mercatorum / repleta and quinaria / testacea). These differences are not accounted for simply by the different parasite load between these transfecteds hosts (although this has a significant role) and thus, these data are consistent with both a host and parasite co-interaction. The implications for host and parasite co-evolution as well as horizontal transfer of the parasite between hosts will be discussed.

08-078

WOLBACHIA -MEDIATED CYTOPLASMIC INCOMPATIBILITY IN *DROSOPHILA*: COMPARISON OF PROTEIN PROFILES BETWEEN INFECTED AND UNINFECTED FLIES

T.Sasaki^{1,2}, H. R. Braig¹ & S. L. O'Neill¹
Department of Epidemiology & Public Health, Yale University, New Haven, CT USA -1, Department of Biological Sciences, Graduate School of Science, University of Tokyo, Hongo, Tokyo, Japan - 2

Wolbachia infections have been observed in various arthropod species from diverse orders, in most cases being associated with the phenomenon of cytoplasmic incompatibility. Cytoplasmic incompatibility is usually expressed when infected males mate with uninfected females. Eggs from such a cross do not successfully complete karyogamy. Since *Wolbachia* are shed from sperm during maturation, it is conceivable that *Wolbachia* condition the developing spermatid, and the conditioned sperm can be rescued exclusively in the eggs containing *Wolbachia*. In an attempt to better understand the molecular mechanism of cytoplasmic incompatibility, we studied the protein synthesis by *Wolbachia* in several *Drosophila* strains, and found a predominant *Wolbachia* protein whose molecular weight varied among strains. We also report the protein profiles of sperm from *Wolbachia* infected and uninfected male flies.

08-079

POSTMATING REPRODUCTIVE ISOLATION BETWEEN *CHRYSOPEA QUADRIPUNCTATA* BURMEISTER AND *C. SLOSSONAE* BANKS (NEUROPTERA: CHRYSOPIDAE)

G.S. Albuquerque, C.A. Tauber¹, M.J. Tauber¹
Laboratório de Proteção de Plantas, Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, Brazil - ¹ Department of Entomology, Cornell University, Ithaca, USA

In laboratory tests, *C. quadripunctata* showed geographic variation in a postmating, prezygotic barrier to hybridization with its sister-species, *C. slossonae*. When paired with *C. slossonae* males, *C. quadripunctata* females from populations that are sympatric with *C. slossonae* had lower incidences of fertile oviposition than those from allopatric populations. Sperm was transferred to *C. quadripunctata* females in all the interspecific pairings, but lack of fertile oviposition was associated with sperm remaining in the bursa copulatrix, rather than reaching the spermatheca. The *C. quadripunctata* females that failed to lay fertile eggs when crossed with *C. slossonae* males invariably produced viable *C. quadripunctata* offspring (no hybrids) within one day after the heterospecific male was replaced with a conspecific one. Thus, we concluded that the barrier to hybridization may involve a species-specific interaction that influences movement of sperm to the spermatheca. When *C. slossonae* females were paired with *C. quadripunctata* males, the incidences of fertile oviposition were high and there was no apparent geographic variation in the degree of hybridization. As with *C. quadripunctata* females, unsuccessful hybridization of *C. slossonae* females was associated with retention of sperm in the bursa copulatrix. The patterns of inter- and intraspecific variation in hybridization indicate that *C. quadripunctata* harbors variation in the mechanism that controls sperm movement to the spermatheca and that the evolution of reproductive isolation between *C. quadripunctata* and *C. slossonae* may include natural selection for increased expression of this mechanism.

08-081

SPECIES PHENOMENA ON BIPARENTAL A-LIVES

Y. Sawada
Museum of Nature and Human Activities, Hyogo, Japan
e-mail: saw@nat-museum.sanda.hyogo.jp

On the species phenomena, such as species entity, speciation event, diversity among local populations and intraspecific variety, biologists have proposed many models, concepts concerned and hypothetical visions. The validities of them, however, have been assessed simply by imagination subjectively. Exploiting the methods of simulation or A-Life, we are able to reconstruct the models, to observe the dynamics objectively and to evaluate or reject them fairly.

In our system (DEME, breeding A-Life species complex *Stigmaticon cornigera*; DEMEV, *S. mundana*; DEME(W), *S. fenestris*), the rules are derived from three fundamental dynamical principles, (1) individuals reproduce through bisexual interbreeding, (2) combinations of character states affect success or failure of the mating, and (3) the character states are inherited, but mutation may break out accidentally. The "biological concept of the species" is fully adoptable to these kinds of A-Lives. We can identify or discriminate individuals to the species observing the concept (definition) of species.

The system emerges well-nigh every species phenomena, the unity of species, the transition among generations, character differentiation in local populations of the species, formation of cline, allo- and parapatric speciation and hybrid zone. When the concept of "niche" is appended in the system (ECDM, *S. macacobia*), the sympatric speciation and the secondary sympatricity were observed. Note that the concept of "adaptation" is not assigned in the both systems at all.

08-080

EXTENSIVE MOLECULAR SIMILARITY IN SYMPATRIC FRUIT FLY SPECIES

J. Morrow, Y. Bastian, M. Frommer, J.A. Sved
School of Biological Sciences A12, University of Sydney, NSW 2006, Australia

The morphologically similar species *Bactrocera tryoni* and *Bactrocera neohumeralis* occur in sympatry along the eastern seaboard of Australia. The distribution of *B. neohumeralis* is contained within the distribution of *B. tryoni*. The host range of the two species is very similar, and the two species have been known to emerge from the same piece of fruit. The basis for the maintenance of speciation appears to be mating time. Mating in *B. tryoni* occurs at dusk, whilst in *B. neohumeralis* mating occurs during the middle of the day.

Sequences from mitochondrial regions have been obtained for many individuals of each of the two species. These show a surprising level of homology, with shared polymorphic sites and similar average genetic distances within and between species. Following this finding, we searched for differences in non-coding nuclear DNA sequences and in the *period* gene which is involved in circadian rhythms. High levels of homology have been found for all regions studied.

Alternative hypotheses for the extensive homology are (1) very recent divergence of the two species, (2) high levels of introgression. Both explanations are difficult to reconcile with the maintenance of the mating dimorphism.

08-082

INVESTIGATION OF HYBRID DISGENESIS IN INDIVIDUALS FROM RECIPROCAL CROSSES BETWEEN POPULATIONS OF *Anastrepha fraterculus* (DIPTERA: TEPHRITIDAE) FROM SOUTHERN BRASIL.

M. Taufer, I.B.M. Da Cruz, A.K. Oliveira
Departamento de Genética, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brasil

The fruit fly specie *Anastrepha fraterculus* is one of the pest in the fruit orchards in the southern Brasil. Several authors considering this species as a complex of cryptic species. This work analysed several aspects related with the specie's reproduction crossing two populations isolated. No occurrence of hybrid inferiority was found in egg-adult viability ($\chi^2=4.603$, DF=3) and hybrid disgenesis when the Kruskal-Wallis test was applied to detection of disgenic gonads considering the size and the number of ovocits per ovary [H=1.18; DF=3 (ovaries), H= 0.94, DG=3 (testicles) and H=3.38, DF=3 (ovocits). The results suggested that populations analysed are the same specie. This work starts the possibility of future investigations with crosses between populations located geographically more distant. Grants and fellowships: CNPq, ABPM.

08-083

REPRODUCTIVE ISOLATION OF PARAPATRIC *PONTIA DAPLIDICE* AND *P. EDUSA* (LEPIDOPTERA: PIERIDAE) IN A CONTACT ZONE

L. Büchi, A. Scholl

Institute of Zoology, Department of Population Biology,
University of Berne, Berne, Switzerland

The closely related parapatric butterfly species *P. daplidice* and *P. edusa* have a contact zone in Northern Italy, as we have shown previously. This contact zone is associated with a rather small hybrid zone, where both F₁- and backcross hybrids are observed at low frequencies with strong deviation from Hardy-Weinberg equilibria, as revealed by enzyme electrophoresis using four diagnostic loci. These butterflies are considered medium distant migrants. However, there is no evidence of gene flow beyond the hybrid zone as shown by the allozyme data.

We analyse parameters that potentially account for the reproductive isolation of the butterfly species concerned. These include estimates of dispersal with capture-mark-release techniques, spermatophore counts, analysis of selective mating with allozyme techniques, and comparison of mortality and rates of development under laboratory conditions (30°, 17L:7D, using *Reseda lutea* as food plant) of larval instars and pupae among F₁- and backcross hybrids as compared to the pure forms.

08-085

GENOTYPIC STRUCTURE AND REPRODUCTIVE ISOLATION BETWEEN SYNTOPIC POPULATION OF *CHALCOLESTES VIRIDIS* AND *C. PARVIDENS* IN CENTRAL ITALY (ODONATA: LESTIDAE)L. Dell'Anna¹, E. De Matthaeis¹, M. Cobolli² & C. Utzeri¹¹ Dip.to Biologia Animale e dell'Uomo, Università "La Sapienza", Roma, Italy² Dip.to Scienze Ambientali, Università di L'Aquila, Italy

Chalcolestes viridis and *C. parvidens* have been recognised as separate species quite recently (Cobolli et al., 1994. Atti 17° Congr. naz. ital. Ent., pp. 77-82). The two taxa were distinguished on the basis of the male's superior abdominal appendages (the cerci), while it was not possible to separate either females and the preimaginal stages. In a pond in Castel Porziano, Roma, Italy, both species coexist, generating pure and hybrid offspring. An investigation on genetic structure, morphology and ecology of the two species was carried out to evaluate the amount of hybrid specimens in the syntopic area and to identify the pre-mating isolating barriers between the two species. A morphometric analysis (total body length) of samples from the syntopic and allotopic areas (Greece, Spain) has shown that in syntopy, the males of *C. parvidens* are significantly shorter than those of *C. viridis*, and the same is valid for the females which were pairing with the males of the two species. Also in syntopy, the two species show peaks of activity at different times in the day. As to allotopic populations, neither body length nor activity times differ. In hybrid specimens, either the shape of anal appendages can be intermediate between those of genetically pure specimens, or morphological characters of the two species can coexist. The genotypic structure was investigated by means of electrophoresis of multilocus enzymes. The average genetic distance between the two species is $D_{NEI} = 0.586$. The two species differ at 7 diagnostic loci out of 16 checked. Hybrid specimens were heterozygous at either all loci (F₁-hybrids) or some of the diagnostic loci. The former showed a mixed morphology, while the latter could show parental morphology (particularly so those which were heterozygous at a single locus). The overall percent of F₁-hybrids in the overall sample (N = 131) was 4.6 %, which matches the percent of interspecific pairs (4.7 %) in the same area (females belonging to each of the two species were identified by electrophoresis). Despite the occurrence of some hybridisation, which witnesses some genetic and morphological compatibility, the two species maintain isolated by such barriers as different activity times and different shape of anal appendages.

08-084

SPECIATION IN GREEK BUSHCRICKETS OF THE *POECILIMON PROPINQUUS*-GROUP (ORTHOPTERA, ENSIFERA, PHANEROPTERIDAE)

A. Wendler

Institut of Zoology II, Staudtstraße 5, D-91058 Erlangen, Germany

The mechanisms which lead to the evolution of new species are not well understood. The most powerful explanation originate from Mayr and is known as the "Biological Species Concept" (BSC). According to this concept most species evolved in allopatry. For secondary contact the "BSC" predicts that character displacement should be a common event, but very few cases of character displacement are known. This problem lead to the formulation of alternative concepts. In this contest I have tested the prezygotic isolation in six species of the *Poecilimon propinquus*-group. These species are parapatrically distributed in Greece. Barriers against hybridisation may consist of song or structure of male cerci. The mating behaviour between different species were observed in 27 interspecific pairing and crossing experiments using 600 males and females. Neither the song discrimination by females nor the fit of male cerci to female basal fold show evidence for reinforcement. I present an alternative explanation for song discrimination by females.

08-086

ANALYSIS OF THE MITOCHONDRIAL GENOME OF FLIES THAT CAUSE MYIASIS BY POLYMERASE CHAIN REACTION AND RFLP.

A. C. Lessinger and A. M. L. de Azeredo-Espin

Departamento de Genética e Evolução e Centro de Biologia Molecular e Engenharia Genética-CBMEG, Universidade Estadual de Campinas, Campinas, S.P., Brasil.

Animal mitochondrial DNA (mtDNA) has been used extensively in studies of evolutionary and population genetics as well as in systematics of closely related species. More recently, an emphasis has been given on overall mitochondrial genomic structure. The advent of the polymerase chain reaction (PCR) with the use of universal mtDNA primers permits the sequencing of the DNA of species for which no previous sequence information exists.

Flies that cause myiasis from Calliphoridae and Cuterebridae families are all obligate or facultative parasites in the Neotropical region. Blowflies are typically necrophagous and saprophagous, and are the major initial decomposers of animal carcasses. The New World screwworm fly, *Cochliomyia hominivorax* and the bot fly *Dermatobia hominis* are the obligate ectoparasites considered the most important pests of warm-blooded livestock in Brazil. However, it also parasitizes wild animals and humans.

At the genetic level, relatively little is known of the molecular markers to estimate intra and interspecific variability of Brazilian blow flies and bot fly.

This study reports the characterization of mtDNA regions of six dipteran species causing myiasis: *Cochliomyia hominivorax*, *Cochliomyia macellaria*, *Chrysomya megacephala*, *Chrysomya albiceps*, *Phaenicia eximia* and *Dermatobia hominis* using the PCR of the control region (called the A+T rich region in insects), the Cytochrome Oxidase genes subunit I and II (COI/II), the rRNA 12S and 16S and the Cytochrome b region. The A+T rich region varies in length from 1200 to 1800 nucleotides for these species. The differences in the mtDNA control region observed by PCR were useful to identify species-specific markers in the amplified DNA. Diagnostic restriction sites with *TaqI* in COI/II recognized three genera, *Cochliomyia*, *Phaenicia* and *Dermatobia*. Both regions are particularly well suited as molecular markers for species identifications and are indicative of variable and conservative sites in the mtDNA molecule.

These results suggest a size variability for A+T rich region among the six studied species and were also useful to predict diagnostic restriction sites for COI and COII regions. The PCR-RFLP technique applied to characterize these dipteran species should provide material for their further analysis both structurally and functionally and their comparisons with other insect mtDNAs.

08-087

MITOCHONDRIAL DNA LENGTH VARIATION IN THE PEA APHID
ACYRTHOSIPHON PISUM.

L. Birkle, A.E. Douglas
Department of Biology, University of York, York, UK.

The genetic relationships among 29 European clones of the pea aphid were investigated by mitochondrial DNA RFLP, using a modified alkaline lysis technique. Genetic variation at restriction sites was not found, reflecting the generally low variation found in aphids. However, one restriction site was able to distinguish all these European clones from pea aphids studied in N. America.

Length variation (which may correspond to variable tandem repeats) was found at 2 regions of the mitochondrial DNA molecule. Three size classes were obtained at region 1, which contained the A+T-rich region; and four size classes at region 2 which is located at the ND3 to ND5 region of the molecule. There was no association between variation at the two regions of the molecule. The different length variants were not correlated with host-plant affiliations of the aphids.

08-089

RANGEWIDE VARIATION OF MITOCHONDRIAL DNA AMONG
POPULATIONS OF THE MARITIME PINE SCALE
MATSUCOCCUS FEYTAUDI DUC. (HOMOPTERA:
MARGARODIDAE)

C. Burban¹, R. Petit², H.Jactel¹
¹ Laboratoire d'Entomologie Forestière, INRA, Gazinet, France - ²
Laboratoire de Génétique et d'Amélioration des Arbres Forestiers,
INRA, Gazinet, France.

Matsucoccus feytaudi is a specific pest of maritime pine (*Pinus pinaster*). Western populations of the insect are endemic whereas eastern populations are thought to be recently introduced. They developed severe outbreaks in Southeast France and are presently spreading in the north of Italy. A future epidemic evolution is also feared in Corsica where a scale population has just been discovered by pheromone trapping. The relationship between potential outbreaks and the origin of *M. feytaudi* populations was thus investigated by studying the phylogeography of the pest. Scales were sampled over the maritime pine natural range. Mitochondrial DNA of single minute males was amplified using PCR, and analysed with the restriction fragment length polymorphism (RFLP) and single strand conformation polymorphism (SSCP) techniques. Preliminary results are presented, which precise the origin of the newly discovered populations and outline the evolutionary history of this pest.

MITOCHONDRIAL DNA HAPLOTYPES AND QUATERNARY RANGE
CHANGES OF *PHLEBOTOMUS PAPATASI* (DIPTERA: PSYCHODIDAE)

Selma Esseghir¹, Paul Ready, Riadh Ben-Ismaïl¹
Molecular Systematics Laboratory, Department of
Entomology, The Natural History Museum, London U.K.
¹L.E.E.P., Institut Pasteur de Tunis, Tunis, Tunisia

The phlebotomine sandfly *Phlebotomus* (*Phlebotomus*) *papatasi* has an extensive geographical range in the subtropics of the Old World, extending from Portugal and Morocco to the Indian subcontinent, and is found on many of the larger Mediterranean islands. It occurs at altitudes from sea-level up to 2100m, and geographical populations display varying degrees of diapause (overwintering as fourth instar larvae). However, it is only abundant in semi-arid and arid bioclimatic zones and is rarely collected in northern Spain, southern France and northern Italy. As such, it is believed that its range contracted considerably during Quaternary glacial periods. Southern hybridization analysis with homologous probes, the (direct) sequencing of PCR products and PCR-RFLP analysis have all been used to characterize mitochondrial haplotypes found in 15 populations of *P. papatasi* from 10 countries, from Spain and Tunisia in the West to Afghanistan and India in the East. Comparative (phylogenetic) sequence analyses have been used to relate these populations and those of other *Phlebotomus* species and to postulate the geographical range of *P. papatasi* from the late Quaternary back to the Miocene-Pliocene, when we conclude it diverged from the morphologically and ecologically similar *Phlebotomus* (*Phlebotomus*) *duboscqi* which is now restricted to the sub-Saharan Sahel. This project is supported by grants from the British Council (Tunis Office) and the CEC/EU (Brussels).

GENETIC VARIATION IN GEOGRAPHIC POPULATIONS OF THE SCREWORM
FLY (Diptera: Calliphoridae), FROM BRAZIL.

A. M. L. de Azeredo-Espin
Dept. de Genética e Evolução e Centro de Biologia Molecular e Engenharia Genética-CBMEG, Universidade Estadual de Campinas, São Paulo, Brasil
Screwworm, *Cochliomyia hominivorax* is an obligate ectoparasite causing severe myiasis in warm-blooded livestock, wildlife and humans throughout the Neotropical Region. The genetic analysis based on cytogenetics and allozyme loci studies have been conducted previously in several geographic populations of screwworm flies from North and Central America. The results obtained show no evidence of reproductively isolated populations, suggesting that *C. hominivorax* is a single, highly polymorphic species. In this work, cytogenetic and mtDNA analysis by RFLP were used to examine genetic variation and population structure of screwworm flies in seven populations from five Brazilian States: Amazonas, Bahia, Minas Gerais, São Paulo and Rio Grande do Sul. Six different karyotypes (2n=12) were identified through morphologic analysis of metaphase chromosomes with Giemsa and Quinacrine staining. The main karyotypic interpopulational variation refers to the length and morphology of the chromosomes, the location and numbers of secondary constrictions of autossomes II, III and VI and the sex chromosomes. The Q-band showed differences in the intensity and location of the fluorescent regions in pairs II, III and sex chromosomes. Cytogenetic studies have demonstrated the existence of interpopulational variation but are unable to unambiguously resolve screwworm fly population structure. Restriction enzyme analysis of mtDNA variation is a likely tool to study intraspecific population structure in screwworm fly from Brazil because of considerable polymorphism as was demonstrated in previous work conducted in five populations in São Paulo State. Here, we extend that analysis by means of an increased number of geographic screwworm flies populations. The total DNA of 520 individuals sampled was digested with 15 restriction endonucleases and probed with five cloned *Hind* III fragments of *C. hominivorax* mtDNA. The survey revealed that five enzymes *Clal*, *Hae*III, *Hind*III, *Msp*I and *Pvu*II were suitable to detect mtDNA variation among the populations. Based on the fragment patterns obtained for these five enzymes, a total of 14 haplotypes in combination was detected. Estimates of mtDNA sequence divergence (d) between haplotypes ranged from 0.015 to 0.040. The cladogram of the geographical distribution among the observed haplotypes suggests that the sampled screwworms probably belong to a single evolutionary lineage with populations interconnected by reduced gene flow.

A PHYLOGENY OF APHID PARASITIDS (HYMENOPTERA:APHIDIIDAE) BASED ON DNA SEQUENCE OF MITOCHONDRIAL 16S rRNA AND NADH1 DEHYDROGENASE GENES.

Srini Kambhampati, Paul Smith and M. Mackauer¹

Department of Entomology, Kansas State University, Manhattan, Kansas, USA.

¹Department of Biological Sciences, Simon Fraser University, Burnaby, B.C. Canada.

The hymenopteran family Aphidiidae consists of about 50 genera and more than 400 described species, which parasitize exclusively aphids. The importance of aphidiids stems from the fact that they are important biological control agents of aphid pests throughout the world. Various hypothesis concerning the generic- and species-level relationships, based on morphological characters exist. In this poster, a phylogeny for 15 genera and 45 species of aphidiids based on DNA sequence analysis of portions of the mitochondrial 16S rRNA and NADH1 dehydrogenase genes will be presented. The results of the analysis generally confirmed the existing hypotheses concerning generic-level relationships. The implications of the molecular phylogeny to the evolution of pupation habit (inside vs. outside the host) and host range (monophagy vs. oligophagy) will be addressed. Supported by USDA-NRI grant 9401865 to SK and MM.

HOST-PLANT RELATIONS OF *OSTRINIA NUBILALIS* AND FACTORS OF EVOLUTION IN THE GENUS *OSTRINIA* (LEPIDOPTERA: PYRALIDAE)

A.N. Frolov

Department of Forecasting, All-Russian Institute for Plant Protection, St.-Petersburg, Russia

The European corn borer (ECB), *Ostrinia nubilalis*, and allied forms are shown to be characterized by complex population structure adaptively connected with the general ecological features: humidity conditions, thermic regimes, and host plants. Depending on the action of the factors mentioned, borers had formed genetic adaptations which allowed them to exist in wide and differentiated life space (Frolov, 1994 a,b).

Occupation of host plants by ECB seems to be performed in two different strategies of host exploitation: i) species-generalized but stages-specialized (feeding occurs on mono- and dicotyledonous hosts at stages near flowering), and ii) species-specialized but stage-generalized (few monocotyledonous species infested at wide range of their stages). The existence of strategies is supported by ethological isolation (Frolov, 1994 b,c). Certain level of specificity in host-plant relations with maize, sorghum and millet was observed among populations following the second strategy of host exploitation.

The study was in part supported by grants from the ISF (NTH000 and NTH300).

GENETIC VARIATION IN MITOCHONDRIAL DNA OF *COCHLIOMYIA MACELLARIA* (DIPTERA:CALLIPHORIDAE) FROM BRAZIL

J. S. Valle and A. M. L. de Azeredo-Espin

Departamento de Genética e Evolução e Centro de Biologia Molecular e Engenharia Genética-CBMEG, Universidade Estadual de Campinas, Campinas, São Paulo, Brasil

Cochliomyia macellaria belongs to an endemic New World genus and ranges from southern Canada to Argentina, but it is especially abundant in the tropical regions. It is a carrion breeder which is a secondary agent of myiasis and a purely saprophagous species, which is perhaps the most widely distributed calliphorid in the Americas. This species has been implicated as a mechanical vector of human and animal diseases. Recently, the Western Hemisphere has been invaded by four Old World blow flies of the genus *Chrysomya* (Robineau-Desvoid). These species, particularly *Chrysomya albiceps* and *C. putoria*, occupy the habitats of the native species, including *C. macellaria*, providing interspecific competition, and have caused a population reduction and movement of *C. macellaria* in several regions of Brazil and Peru.

At the genetic level, investigations of natural populations of *C. macellaria* have been limited to karyotypic characterization. Investigation of genetic variability among populations of *C. macellaria* would help understand historical patterns of dispersal and current levels of gene flow.

In this report restriction fragment analysis (RFLP) of mitochondrial DNA (mtDNA) was used to examine genetic variation of six populations of *C. macellaria* from Brazil. The total DNA of 371 individuals were digested with 13 restriction endonucleases and probed with the entire mitochondrial genome of *Cochliomyia hominivorax*. Five endonucleases, *EcoRV*, *HindIII*, *MspI*, *PvuII* and *XhoI*, detected polymorphism, yielding thirteen haplotypes in combination. Nucleotide divergence estimates (d) between pairs of haplotypes ranged from 0.2% to 10%. Restriction site heteroplasmic individuals were found in two analysed populations. These results have demonstrated variability in mtDNA of this species in Brazil and revealed the existence of a probable "refuge" of this blow fly in the Amazon region.

SEQUESTRATION OF A LARGE VARIETY OF TOXIC SECONDARY PLANT METABOLITES BY CLOSELY RELATED SAWFLY SPECIES

J.-L. Boevé, M. Hilker

Institut für Zoologie, Freie Universität Berlin, Germany

Sawfly larvae of the tribe Phymatocerini are specialists on one plant taxa such as *Veratrum*, *Polygonatum*, *Iris*, *Helleborus*, *Ranunculus* or Poaceae. A sequestration of alkaloids from *Veratrum* is known to occur in one sawfly species. The question is whether sequestration is a general phenomenon for the Phymatocerini. It would bring us to a rare situation where closely related insect species have to deal chemically with a large variety of secondary plant metabolites which possess toxic properties. In the plant genera mentioned above, steroidal alkaloids, quaternary alkaloids, steroid saponins, spiro-bicyclic triterpenoids, and lactones are major chemical types. Most of these chemicals are known to have a toxic effect on vertebrates and/or invertebrates. During a field season in Switzerland, eight Phymatocerini species were collected. The integument of the larvae was wounded easily, and disturbed larvae remained immobile. Moreover, the hemolymph of the larvae, tested on ants, proved to act as a feeding deterrent. By chemical analyses, the hypothesis that sequestration could occur recurrently in several species was investigated. I discuss from an evolutionary point of view the question whether sequestration could have evolved as a trait related to the high toxicity of secondary plant metabolites.

08-095

WAS THERE A COEVOLUTIONARY RACE BETWEEN THE STAR ORCHID *ANGRAECUM SESQUIPEDALE* AND THE HAWKMOTH *XANTHOPAN MORGANI PRAEDICTA* ?

L. T. Wasserthal

Institut für Zoologie I, Staudtstr. 5, D-91058 Erlangen, Germany

Sphingophilous flowers are adapted to engage hawkmoths for their pollination needs by evolving long tubes or spurs with deeply situated nectaries exclusively accessible for hawkmoths. A famous and extreme example of such a flower is *Angraecum sesquipedale*. Darwin (1862) hypothesized, that this flower must have evolved the long spur as an adaptation to the long tongue of a hawkmoth and that the tongue on the other side must have increased its length in the course of an evolutionary race. This idea of coevolution has recently been emphasized (Nilsson 1988). There is however, evidence only for the advantage of spur elongation for increasing the orchid's fruiting success (Nilsson 1988) - not for the reciprocal increase in tongue length.

Investigations in the field and flight cage support the hypothesis, that the typical specializations of the hawkmoths are adaptations against predation: As generalist feeders most hawkmoths visit a variety of less specialized flowers. By their long tongue combined with hovering flight, hawkmoths keep distance to the flower during nectar uptake and diminish the risk of being captured especially by ambushing predators e. g. spiders. By shortening the stay time ("flower jumping"), often combined with incomplete flower exploitation, the moth can further reduce the danger of being captured. The Malagasy hawkmoths with the longest tongues of the genera *Xanthopan*, *Coelonia* and *Agrilus* exhibit a "swing-hovering" flight which enables them to fully deplete "normal" flowers without the necessity to stay on the spot and thus renders a predator's attack almost impossible.

The pollination of *Angraecum* by *Xanthopan* is described for the first time and the mechanism by which the flower prevents the hawkmoth from "swing-hovering". A model is presented which explains the evolution of extremely long spur of this angraecoid orchid on the basis of (anti-predator-) preadapted hawkmoths instead of Darwins model of a coevolutionary race.

ENVIRONMENTAL FACTORS INFLUENCING THE VISITS OF *TETRAGLOSSULA* SPP (HYMENOPTERA: COLLETIDAE) TO THE FLOWERS OF *LUDWIGIA ELEGANS* (ONAGRACEAE)

M. Gimenes, M.D. Marques

Museu de Zoologia, Universidade de São Paulo, São Paulo, Brazil.

The interaction between the flowers of *Ludwigia elegans* and *Tetraglossula* spp was studied in three areas in São Paulo, Brazil (Mairinque, MA, Campos do Jordão, CJ, and Ribeirão Preto, RP), in relation the morphological, behavioural, phenological and temporal aspects.

Tetraglossula bigamica (RP) and *Tetraglossula ventralis* (MA and CJ) were the most frequent species on the flowers. They were seen from December to May, when *L. elegans* shows its blossoming peak.

During its months of activity, *Tetraglossula* spp showed a circadian rhythm of pollen collection synchronized with the opening of the anthers of *L. elegans*. These rhythms were probably influenced by the light/dark cycle, as they did not occur in the night and by the environmental temperature, because interaction was not observed below 18 °C at the three areas.

The females of *Tetraglossula* spp collected pollen frantically rubbing the abdomen against the anther. Pollen was kept in the rigid, long, and simple hairs of the abdominal scopa.

From the results it may be concluded that *Tetraglossula* spp were the most efficient pollinators of *L. elegans* due to their frequency of occurrence and morphological, behavioural, and temporal adaptations. The light/dark cycle and environmental temperature seem to play important roles in the interaction, providing daily synchronization and annual adjustments between bees and flowers.

MEXICAN DIABROTICITES (COLEOPTERA: CHRYSOMELIDAE) AND CUCURBITACEAE: AN EXAMPLE FOR CHEMICALLY MEDIATED INSECT-PLANT COEVOLUTION?

A. Ebcn, Centro de Ecología, Universidad Nacional Autónoma de México, México, D.F., México

Choice tests were conducted to determine relative degree of specialization of feeding behavior of 8 Mexican diabroticite species in the genera *Diabrotica* and *Acalymma* (Chrysomelidae: Luperini). Adult beetles were offered a choice between cotyledons of a non cucurbitacin-containing cucurbit, corn and beans. In a second assay a cucurbitacin-containing (bitter) cucurbit was added to the array of plants offered. All species showed distinct preferences in the first assay. When the bitter cucurbit was included, all species tested changed their host choice and significantly preferred the bitter cucurbit. This observation led to another series of choice tests, offering a non cucurbitacin-containing cucurbit and 2 cucurbits which contained either one of the 2 primary types of cucurbitacin. All species significantly preferred the bitter over the non bitter cucurbits and cucurbitacin B over cucurbitacin E-containing cotyledons.

These results indicate that the association of diabroticites with Cucurbitaceae is partially mediated by plant secondary compounds.

The role of cucurbitacins for the hypothesized coevolutionary association of diabroticites with cucurbits and for the evolution of oligo- and polyphagy in diabroticites is discussed.

SYNCHRONISATION BETWEEN HESPERIID BUTTERFLIES (INSECTA: LEPIDOPTERA) AND THEIR NECTAR PLANTS

S. Pfaff

Institut für Allgemeine und Spezielle Zoologie, Bereich Tierökologie, Justus-Liebig-Universität Giessen, Germany

Five skipper species (Lepidoptera: Hesperidae), *Thymelicus sylvestris*, *T. lineola*, *T. acteon*, *Ochlodes venatus*, and *Hesperia comma*, their nectar plants and preferences were investigated in summer 1994. The study areas were dry and wet meadows and a forest in Middle Hesse at about 200 to 350 m above sea level. The periods of blooming time and the abundance patterns of the nectar plants were determined.

The abundance patterns of the skipper species were recorded on transects. Evidence was found for a synchronous phenology between the skipper species and some of their frequently visited nectar plants. Peaks in the flight period of the skippers correlate with peaks of the blooming time of the special nectar plants. At some sites syntopically flying *Thymelicus*-species show differences in the choice of their most frequented nectar plants that correlate with differences in their phenology. Possible causes of the synchronisation are discussed with special regard to a co-evolutionary relationship, niche-choice and energy balance. Potential implications for management practices (e.g. unfavourable grazing or mowing times) are discussed.

08-099

POLLINATORS AND VISITING INSECTS OF INFLORESCENCES OF THE *EUTERPE OLERACEAE* MART. (ARECACEAE) IN EASTERN AMAZONIA.

M.A.G. Jardim, M.L.J. Macambira¹

Department of Botanic, Museu Paraense Emílio Goeldi/CNPq - 1 Department of Zoology/Entomology, Museu Paraense Emílio Goeldi/CNPq, Belem, Para, Brazil.

This study evaluates the floral biology of "açai" palm tree (*Euterpe oleraceae* Mart.) in a natural population located on Combu Island (25° 48' W, 1° 25' S), Pará, Brazil. The observations were carried on from January to December, 1991. The results showed that *E. oleraceae* is a monoic, dicogamous and protandric species. The bracts open five days after maturation. The male flowers remain opened between 10 and 12 days in the inflorescences. The female flowers open after the male flowers have fallen completely and remain receptive during five days. Both male and female present diurnal anthesis. The insects observed visiting the inflorescences belong to the following orders: Coleoptera (11 species), Hymenoptera (4 species), Diptera (3 species) and Homoptera (1 specie). The possible pollinators were 4 species of beetles.

08-101

THE IMPACT OF REED BED MOWING ON THE GENETIC STRUCTURE OF *Lipara lucens* POPULATIONS.

M. Santens, R. Stoks, L. De Bruyn, T. Backeljau & R. Verhagen
University of Antwerp (RUCA), Department of Biology, Evolutionary Biology Group, Antwerp, Belgium santens@ruca.ua.ac.be

Reed beds are detritus-based ecosystems. Every year large amounts of litter accumulate which results in the drying out of the ground surface. This can cause major conservation problems for the reed beds and its inhabitants. Mowing is one of the main management methods used to reduce litter input. Although this practice conserves the reed bed for drying out, it can strongly influence the population structure of invertebrate animals by causing a drastic reduction of population numbers. Especially endophagous herbivores such as gall-forming species, whose larvae develop in the above ground situated plant structures, are assumed to be highly vulnerable.

Here we study the genetic consequences of mowing on *L. lucens*, a strict monophagous gall-forming parasite of the common reed *Phragmites australis*. We compared the genetic structure of six populations of mown and unmown parts of two large reed beds near Antwerp, Belgium. Mowing during late winter or early spring, with removal of the litter, causes almost complete extinction of *L. lucens* populations. Although recolonization occurred fast during the present study (the following year), genetic population structure is clearly affected. We found a consistent departure from Hardy-Weinberg equilibrium in populations from mown reed beds. Furthermore, mowing leads to a drastic decline in genetic variability.

08-100

THE ROLE OF DISTANCE AND HOST-PLANT ASSOCIATIONS IN THE DIFFERENTIATION OF *TETRANYCHUS URTICAE* POPULATIONS (ACARI: TETRANYCHIDAE). A MULTILOCUS ALLOZYME ANALYSIS.

A. Tsagkarakou^{1,2}, M. Navajas^{1,2}, N. Pasteur²

1. Laboratoire de Zoologie, INRA, Montpellier, France - 2. Institut des Sciences de l'Evolution (CNRS, URA 327), Laboratoire Génétique et Environnement, Université de Montpellier II, Montpellier, France

Tetranychus urticae Koch is a phytophagous mite with a world-wide distribution. It can reach high densities causing important damages on open field and greenhouse cultures. Few studies on the genetic variability of this species have been undertaken mainly due to their minute size. We have used an isoelectrofocusing electrophoresis method on several stacked cellulose acetate membranes as support, which allowed to reveal 4 enzyme systems on single females.

Based on the combined information of four loci, we showed that in Crete (Greece), there was no differentiation between populations of *T. urticae* colonizing different host-plant species (citrus, weeds, tomato, pumpkin and okra) within an area of 50 m². In contrast, populations separated by 150 m or more were significantly different. These results are discussed in relation to the known patterns of migration in *T. urticae*.

08-102

REPELLENT EFFECTS OF HERBIVORE-INDUCED MAIZE VOLATILES ON THE CORN-LEAF APHID, *RHOPALOSIPHUM MAIDIS* (FITCH).

Marco Bernasconi, Ted Turlings¹, Lara Ambrosetti, and Silvia Dorn.
Institute of Plant Sciences, Applied Entomology, ETH Zurich, Clausiusstrasse 25, CH-8092, Switzerland - 1 Current address: Institute of Zoology, University of Neuchâtel, Rue Emile-Argand 11, CH-2007, Neuchâtel, Switzerland

Herbivory by caterpillars is known to induce a reaction in maize plants that results in the emission of a specific blend of volatiles by these plants. The volatiles are highly attractive to natural enemies of the herbivores, but little is known about the effects that the volatiles may have on herbivores themselves.

In laboratory and field studies we investigated the effects of induced maize volatiles on the behavior of winged and wingless morphs of the corn-leaf aphid, *Rhopalosiphum maidis*. For these experiments, maize plants were induced to emit volatiles by mechanically damaging certain leaves and by treating the damaged sites with regurgitate of the Egyptian leafworm *Spodoptera littoralis*. Subsequently, aphids were offered a choice between such treated plants and plants that were left unharmed. In a Y-tube olfactometer as well as in a field experiment, it was shown that, especially the winged aphids, had a preference for healthy, untreated plants.

We propose that odors that maize plants emit after an attack by herbivores may repel aphids because: 1) the odors may indicate the presence of competitors, 2) the odors may indicate the production of defense compounds by the plant, 3) the odors may make the plant more attractive to natural enemies of the aphid, and 4) one of the main compounds in the odor blend is the known aphid alarm pheromone, E-(β)-farnesene.

08-103

CONGRUENCES IN PILOSITY BETWEEN SPECIES OF *OPHRYS* (ORCHIDACEAE) AND THE FEMALES OF THEIR HYMENOPTERAN POLLINATORS (APOIDEA)

P.M. Plrstinger, H.F. Paulus
Institute of Zoology, Depart. Evol. Biology, University of Vienna, Austria

Flowers of the mediterranean genus *Ophrys* offer hymenopteran males a set of sensations by imitating stimuli produced by their females. Attracted olfactorily and visually, the male alights on the orchid labellum and attempts copulation. Tactile cues such as the pilosity pattern and shape of the labellum guide the male to the correct position for pollen transfer. Hair structures, their orientation, density, length and arrangement in specific patterns of 27 *Ophrys* species and the females of their pollinators were investigated by using light and scanning electron microscopy. The function of specific hair patterns in positioning the males correctly on the labellum were tested in field experiments. Although hair structures of orchids are not in detail similar to those found on hymenopteran females, they are arranged and orientated alike on corresponding patches. Ethological studies showed that hair structures and distributions as those of the centre part of the labellum mimic the visual appearance of the female whereas the pilosity of the edge and the tip of the labellum lead to right orientation within a fraction of a second.

08-105

DOES AN *OPHRYS* PLANT CHEAT A POLLINATING MALE BEE MORE THAN ONCE?

M. Ayasse, F. Schiestl, H.F. Paulus, D. Erdmann¹, W. Francke¹
Institute of Zoology, Dept. of Evolutionary Biology, Vienna, Austria - ¹ Institute of Organic Chemistry, University of Hamburg, Germany

Ophrys spp. orchids are mostly pollinated by male bees, which are lured to the orchid by visual cues and volatile semiochemicals. At close range, chemical signals from the flowers release sexual behaviour in the males, acting in a manner similar to the sex pheromones from females. The male bees try to copulate with the flower labellum and thereby transfer pollen from one flower to another. Our field observations show that male pollinators are very rare on *Ophrys* plants. Therefore, strategies that results in males visiting more than one flower in the same inflorescence would be expected to evolve in plants in order to optimise pollination events. Since male bees are able to learn the distinctive odour bouquets of individual females during mating attempts, and use this information to avoid females they have previously mated, one would expect the odour bouquets of *Ophrys* flowers to vary within populations. The aim of our work was to determine whether flower-specific olfactory recognition signals occur in the orchid *Ophrys sphegodes* by conducting 1) behavioural learning experiments with the pollinating male bees of *Andrena nigroaenea* and 2) quantitative chemical analyses of the headspace odours from individual flowers.

Our data from the behavioural tests indicate that male bees learn the odour bouquets of individual flowers during mating attempts and recognise them in further encounters, since they avoid trying to mate with flowers they have visited previously, but not with other flowers, either on the same or on a different plant. Gas chromatographic analyses of individual flower odours showed that the floral volatile bouquets differed between plants as well as between flowers within an inflorescence. We assume that variation in the odour bouquets of individual flowers within an inflorescence raises the chance of more than one flower being visited by the same male and thereby influences the plants pollination success and individual fitness.

08-104

VARIATION OF THE POLLINATOR ATTRACTING ODOR SIGNAL OF *OPHRYS SPHEGODES* SUBSP. *SPHEGODES* MILLER.

F.P. Schiestl, M. Ayasse, H.F. Paulus, D. Erdmann¹, W. Francke¹
Institute of Zoology, Dept. of Evolutionary Biology, Vienna, Austria - ¹ Institute of Organic Chemistry, University of Hamburg, Germany

The Mediterranean genus *Ophrys* is pollinated by sexually excited male Hymenopterans. Its floral scent is the most important cue for eliciting male mating behavior. Although behavioral experiments showed that male bees are able to learn individual odor bouquets of females as well as of *Ophrys* flowers, none of the recent investigations on *Ophrys* scent is concerned with variation of scent emission of single flowers. When single flowers were offered to male bees, a variation of the attractiveness was observed which was probably due to variation of the odor bouquets. We investigated the composition of scent of single *O. sphegodes* flowers, its alteration after pollination, and nocturnal floral scent emission by means of headspace sorption. Odor samples were analyzed by mass spectrometry and gas chromatography.

32 compounds were identified within the volatile bouquets. Aldehydes were the most abundant class of compounds (40-50 %). There was no decrease in nocturnal scent emission, but bouquets collected during day and night were significantly different. Two to four days after pollination, flowers emitted significantly different odor bouquets, and the total amount of scent was significantly lower compared with unpollinated flowers. Preliminary behavioral tests where synthetic compounds were offered to the pollinator bees indicated a certain attractiveness of 2-nonanol, which was emitted in lower amounts and proportion after pollination. Changes within odor bouquets after pollination may lead to lower attractiveness of pollinated flowers, thus guiding subsequent pollinators to unpollinated flowers of an inflorescence.

08-106

MICROHABITAT SEGREGATION OF GUILDS OF NEOTROPICAL ITHOMIINE BUTTERFLIES (NYMPHALIDAE: ITHOMIINAE) AND THE EVOLUTION OF MIMICRY

G. W. Beccaloni
Insect-Plant Division, Department of Entomology, The Natural History Museum, Cromwell Road, London SW7 5BD, UK

Müllerian mimicry theory predicts that there should be convergence among the unpalatable species in an area to give a single aposematic colour pattern. Thus, the observed sympatry of many different butterfly mimicry complexes throughout much of the Neotropical forests requires explanation.

Evidence is mounting that sympatric mimicry complexes dominated by unpalatable Ithomiinae (ithomiines) and also Heliconiinae (heliconiines), are spatially segregated by microhabitat. In this paper data are presented which confirm that sympatric ithomiine complexes are segregated vertically by flight height. Flight height of ithomiines was found to be positively correlated with the height of their larval host-plants. Thus members of a mimicry complex utilise host-plants of similar heights. Flight height and host-plant height were also found to be positively correlated for non-mimetic British woodland butterflies, which suggests that this relationship is independent of mimicry. These and other data indicate that host-plant partitioning between butterfly species in a community results in the formation of microhabitat guilds of species. Mimicry complexes are microhabitat guilds, which suggests that mimicry has evolved between species which share a guild and not between guilds, perhaps through the action of microhabitat-dependent selection.

08-107

HEMOCYTES DNA AMPLIFICATION: A SUITABLE TOOL TO INVESTIGATE NUCLEIC ACIDS ON LIVING INSECTS

F. Venanzetti¹, L. de Pasquale^{1,2}, V. Sbordoni¹¹ Dipartimento di Biologia Università degli Studi di Roma "Tor Vergata" Italy² Dipartimento Scienze Ambientali Università degli Studi l'Aquila Italy

Interestingly enough, purifying DNA from insects hemolymph seems not at all popular to date although a fast and reliable method of sampling DNA without sacrificing the insects could find a broad application in basic and applied research, i.e. population genetics, molecular genetics, parasitology, agricultural entomology, environmental mutagenesis only to mention a few. The hemolymph or blood of insects is a fluid plasma characterized by different types of nucleated cells in suspension. These cells are involved in different processes as tissue formation, storage, phagocytosis and metabolism. Hemolymph contains various inorganic ions determining pH values usually ranging from 6.0 to 7.7 with cell concentrations variable in different species. We pointed out a friendly and very fast procedure for the isolation from hemocytes of genomic DNA suitable for PCR reactions and we assayed this new procedure on insects belonging to different species as the cave cricket *Dolichopoda laetitiae*, the grasshopper *Anacridium aegyptium*, the beetle *Tenebrio molitor* and the leaf insect *Exstatosoma tiaratum*. The DNA obtained from hemolymph samples as small as 5 µl has been employed directly in PCR assays on both nuclear and mitochondrial sequences. This technique is particularly suitable when it is important to preserve viability of individuals; in our laboratory we are applying this methodology to studies concerning evolutionary relationships of cave cricket populations belonging to the genus *Dolichopoda*.

08-109

EVOLUTION-GENETIC ANALYSIS OF THE PALEARCTIC ANOPHELES MACULIPENNIS (DIPTERA: CULICIDAE) COMPLEX

V.N.Stegnii, I.V.Sharakhov, M.V.Sharakhova, A.K.Sibataev, I.E.Wasserlauf

Laboratory of Evolutionary Cytogenetics, Scientific-Research Institute of Biology and Biophysics, Tomsk State University, Tomsk, Russia

The phylogenetic relations and trend of species formation at 8 species of holarctic fauna of *Anopheles maculipennis* Complex were determined on the basis of study of linear and spatial (three-dimensional) organization of polytene chromosomes. The fundamentally new taxonomic index - architecture of polytene chromosomes of generative tissue (ovarian trophocytes) - was revealed. One allows to conduct diagnostics of any species including homosequential groups of species: *An. labranchiae* Fall. - *An. atroparvus* Van Thiel and *An. maculipennis* Mg. - *An. subalpinus* Hack. et Lewis. The peculiarities of molecular structure and polymorphism of heterochromatin at species of *An. maculipennis* Complex were studied. The adaptive features of chromosomal inversion polymorphism in *An. messeae* Fall. were cleared up. The morphological peculiarities of new species - *An. beklemishevi* Stegn. c. Kab. - were revealed.

SATELLITE DNA SEQUENCE VARIATION IN THE GENUS PIMELIA (COLEOPTERA, TENEBRIONIDAE).

J. Pons, C. Juan and E. Petitpierre

Laboratori de Genètica, Facultat de Ciències, Universitat de les Illes Balears, Palma de Mallorca, Spain.

Several species of *Pimelia* from the Canary and Balearic Islands, and from mainland Spain show a highly conserved satellite DNA. This satellite DNA consists of a monomeric unit of 356 bp which is roughly 65% A-T rich. The sequence displays many clusters of three or more A-T residues, which can be related with DNA left superhelix curvature, as demonstrated by their retarded mobility in non-denaturing polyacrylamide gels.

These satellite DNAs have been taken as probes for fluorescent *in situ* hybridization (FISH) on meiotic and mitotic chromosomes where they show binding signals at the pericentromeric regions of all chromosomes, in agreement with the location of C-bands.

The species-specific satellite DNA sequences of *Pimelia* allow to study the phylogeny within the genus and make possible to compare this phylogeny with that based on the mitochondrial DNA.

HEMOCYTES: A GOOD SOURCE OF MITOTIC CHROMOSOMES FROM CIRCULATING CELLS OF INSECTS.

L. de Pasquale^{1,2}, C. Di Russo¹, L. Ferrucci¹, M. Giammatteo³, V.Sbordoni¹.¹Dipartimento di Biologia Università degli Studi di Roma "Tor Vergata" Italy, ²Dipartimento Scienze Ambientali Università degli Studi l'Aquila Italy ³Centro Interdipartimentale di Microscopia Elettronica Università degli Studi l'Aquila Italy.

Hemolymph of insects is a fluid plasma characterized by different types of nucleated cells in suspension. These cells are involved in different processes as tissue formation, storage and phagocytosis. In this study we investigate the mitotic property of hemocytes and report an easy and quick method to obtain mitotic chromosomes from hemocytes of insects. We have experimented this method on two different genera: *Dolichopoda* cave crickets and *Exstatosoma* leaf insects. This method is based on the mitotic property of circulating hemocytes so that it is sufficient to pick up few microliters of hemolymph to obtain mitotic chromosomes. After staining with Giemsa solution and with etidium bromure chromosomes were observed by means of optical microscope and by means of a confocal microscope. This method could be particularly usefull in studies of environmental mutagenesis, agricultural entomology conservation biology and evolutionary biology being possible to analyze the mitotic chromosomes of any individual keeping it alive.

08-111

CHROMOSOME SPECIATION IN PODISMINI GRASSHOPPERS (ORTHOPTERA, ACRIDIDAE) ON SAKHALIN AND THE KURIL ISLANDS

Bugrov A. G., Tchernykh A.A.
Department of General Biology, Novosibirsk State University, Russia

The inversion in the X-chromosome of *Podisma sapporensis* from Sakhalin (Krylion population) ($2n\sigma=23$, NF=24, sex determination is $XO\sigma/XX\sigma$) and that of the translocation of autosome-X-chromosome in the population of this species ($2n\sigma=22$, NF=23, sex determination is neo- $XY\sigma$ /neo- $XX\sigma$) from Golovnin Volcano on Kunashir island has been found. Ethological barriers to mating between specimens of these populations appear to be absent both in the field and in laboratory. The embryos of the hybrid generation have a some mitosis disturbances. It caused the differentiated rate of survival the embryos death of different karyomorphs and the sterility of hybrid males. All its showed the isolation effect of a revealed chromosome rearrangements.

On Kunashir island a new species of the genus *Podisma* (describing as *P. tyatiensis* Sergeev et Bugrov) has been found. the karyotype of which have a short second arms in two pairs of autosomes and the X-chromosome ($2n\sigma=23$) which had not been found in other species of this genus.

All the above allows to suppose that in island grasshopper populations the speciation is accompanied by setting the chromosome isolation mechanisms.

08-113

GENOME MOBILIZATION IN TWO POPULATIONS OF *CHIRONOMUS RIPARIUS* MEIGEN 1804 (DIPTERA, CHIRONOMIDAE) FROM POLLUTED SEDIMENTS

P. Michailova, N. Petrova¹, G. Sella², L. Ramella², F. Regoli³, V. Zelano⁴.

Institute of Zoology, Academy of Sciences, Sofia, Bulgaria - 1 Institute of Zoology, Academy of Sciences, St Petersburg, Russia - 2 Dipartimento di Biologia Animale, Università di Torino, Italy - 3 Dipartimento di Biomedicina, Università di Pisa, Italy - 4 Dipartimento di Chimica Analitica, Università di Torino, Italy.

Two populations of *C. riparius* (from the Piedmont stations Moncalieri on the Po river and Santena on the Banna river) were studied from a cytogenetic point of view. Sediments of both stations had a concentration of some heavy metals (Cu, Cd, Pb, Cr, Fe) which was from two to three times higher than that observed in unpolluted sediments. Especially high was the body concentration of Cu, Fe and Pb in Moncalieri larvae and of Cd and Fe in Santena larvae. No pesticides or herbicides were present. Polytene chromosomes from salivary glands of IV instar larvae (prepupa stage) showed many structural rearrangements, i.e. paracentric heterozygous inversions, deletions, changes in appearance of heterochromatin, partial breakages, amplified as well as under-replicated regions, asynaptic zones, ectopic pairings and a different activity of Balbiani rings and NORs which often appeared in a heterozygous state. Such rearrangements were absent in standard lab populations. The IV chromosome (in which three Balbiani rings and a NOR are located) was the most involved in such rearrangements. However at any larval stage nearly absent were those morphological deformities which are generally considered as markers of a highly polluted environment.

The hypotheses are advanced that concentration of pollutants in the sediments of the two stations is sufficiently high to induce chromosome aberrations but not morphological deformities and that the observed genome mobilization could be considered as an early response to a stressful environment.

This research was supported by a NATO Linkage grant N° 940709, a CNR grant A.I.95.00359.04 and MURST funds (ex 40 %).

08-112

KARYOTYPE EVOLUTION IN THE PARASITIC HYMENOPTERA V.E.Gokhman

Botanical Garden, Moscow State University, Moscow, Russia

The results of chromosome study of more than 200 species of parasitic wasps have demonstrated that the plesiomorphous haploid chromosome number in the group (as well as in the whole Apocrita) is about 10-11. Numbers close to 10 occur in the majority of Ichneumonoidea, Cynipoidea, Diaprioidea, Scelionoidea, Ceraphronoidea and the families Encyrtidae and Eurytomidae from the Chalcidoidea. Evanioidea show higher n values (16). Lower chromosome numbers ($n = 3-7$) found in the Aphidiinae (Braconidae) and the most Chalcidoidea represent their synapomorphies.

Chromosomes of many parasitic wasps are predominantly two-armed and continuously decrease in size within a karyotype. A few ichneumonids (e.g. *Vulgichneumon saturatorius*) however, have highly asymmetric karyotypes, and acrocentric (or pseudo-acrocentric) chromosomes often predominate in wasps with higher haploid numbers.

Following mechanisms of change in chromosome number were detected: tandem fusions, robertsonian rearrangements, polyploidy, aneuploidy, numerical changes in B chromosomes. Among the structural changes, deletions and duplications (mainly of the constitutive heterochromatin), translocations and inversions were observed.

A few cases of population polymorphism have been detected in the parasitic Hymenoptera. C-banding polymorphism was found in *Dirophanes invisor* (Ichneumonidae). The data obtained for the ichneumonid *Tycherus bellicornis* suggest a translocation polymorphism resulting in aneuploidy. A unique B chromosome known in *Nasonia vitripennis* (Pteromalidae) converts diploid zygote into a haploid one.

It may be supposed at present that macroevolutionary changes of karyotype in parasitic wasps may involve virtually all types of rearrangements, and the most usual among them are: tandem fusions, aneuploidy, deletions and duplications of the constitutive heterochromatin, and translocations.

08-114

REVISION OF THE KARYOTYPES OF SPECIES BELONGING TO THE *DIPRION* GENUS (HYMENOPTERA : DIPRIONIDÆ)

J. Rousselet^{1,2}, C. Géri¹, F. Lemeunier²

1 Station de Zoologie Forestière, Institut National de la Recherche Agronomique, Orléans, France - 2 Laboratoire "Populations, Génétique et Evolution", Centre National de la Recherche Scientifique, Gif-sur-Yvette, France

Earlier cytological investigations reported in Crozier's review (1975) characterize the Diprioninae with a range of chromosome numbers from 6 to 14 (with a very large majority of 7 as haploid number). In Maxwell (1958), *Diprion pini* and *D. similis* have a chromosome complement of 7 (haploid male) and 14 (diploid female) while Smith (1941, 1960) found *D. similis* haploid complement with 14 metacentric chromosomes. Their results are contradictory and difficult to explain because of the small size of the chromosomes.

Our present study demonstrates that both species *D. pini* and *D. similis* share the same karyotype : 14 chromosomes for haploid males and 28 for diploid females. The chromosomes are clearly telocentric with different lengths. Several banding methods are presented to characterize the heterochromatin localization. No chromosomal polymorphism was detected during the studies of four different populations of *D. pini*.

Our results disagree with the results previously published and reopen the question of karyotype evolution by doubling of the chromosome number.

08-115

THE LOWEST CHROMOSOME NUMBER OF TIMARCHA: VALIDATION OF T. AURICHALCEA (BECH.) A SPECIES WITH 18 CHROMOSOMES.

J. Gómez-Zurita, J. Pons and E. Petitpierre
Laboratori de Genètica, Facultat de Ciències,
Universitat de les Illes Balears, Palma de
Mallorca, Spain.

The taxa belonging to the complex Timarcha goettingensis share a male meioformula of $9+X_{yp}$ ($2n=20$), where X_{yp} means a sex-"parachute" non-chiasmatic association, and a karyotype made of three large autosome pairs plus a large X-chromosome and six small autosome pairs plus the smallest Y-chromosome. A species of this complex, T. aurichalcea from Central Eastern Spain, has $8+XY$ ($2n=18$) and a karyotype differing from the former due to the lack of the 4th. acrocentric pair and the presence of a rather large Y-chromosome, which is held with the X-chromosome at metaphase I of meiosis by a chiasmatic aggregation (XY).

The Ag-NOR staining and fluorescent *in situ* hybridization, using a ribosomal DNA probe, demonstrates the cytogenetic origin of this species due to an event of centric fusion, changing also the sex-chromosome system from X_{yp} to XY.

08-117

GENETIC ANALYSIS OF WING DIMORPHISM AND RESPONSES TO WING-FORM SELECTION ON LIFE HISTORY TRAITS IN THE WHITEBACKED PLANTHOPPER, SOGATELLA FURCIFERA (HORVÁTH) (HEMIPTERA: DELPHACIDAE)

M. Matsumura

Laboratory of Insect Pest Control, Hokuriku National Agricultural Experiment Station, Joetsu, Niigata, Japan

The whitebacked planthopper, Sogatella furcifera (Horváth) exhibits wing dimorphism. The production of female macropters is most influenced by nymphal population density and is positively density-dependent. Bidirectional wing-form selection was imposed under low and high density conditions. Selection for increasing and decreasing the incidence of macroptery was most effective under antagonistic selection, i. e. selection for macroptery was most effective under low density conditions and selection for brachyptery was most effective under crowded conditions. Crossing experiments using the lines selected for macroptery and brachyptery suggest that the wing-form in S. furcifera is a threshold character under polygenic control and is determined by a threshold response to nymphal density. The realized heritability was 0.512 estimated from the lines selected for macroptery and 0.298 from the lines selected for brachyptery. The relationship between wing-form ratio and nymphal density (i.e. reaction norm) was parallel, which proved that there was no genotype-by-environment interaction between wing-form and density. There was a positive correlated response to selection on nymphal development period, but no consistent responses were detected on either fecundity or adult life span. A significant reduction in both forewing length and flight propensity of macropters was detected in response to selection for brachyptery, which suggests that flight propensity is positively correlated with the incidence of macropters.

08-116

KARYOTYPIC ANALYSIS OF THE GRASSHOPPER ANACRIDUM AEGYPTIUM (ORTHOPTERA, CATANTOPIDAE) BY CHROMOSOME BANDING TECHNIQUES

R. Vitturi, M.S. Colomba

Istituto di Zoologia, Università di Palermo, Italia

During the past twenty years, chromosomal analysis has become notably refined due to the introduction of modern banding techniques which allow a detailed analysis of the chromosomal structure. Such techniques have successfully been employed in cytogenetics of higher vertebrates, man included.

Instead, the scantiness of data concerning G, R, and fluorochrome serial banding and restriction endonuclease digestion in invertebrates is thought to be the result of technical difficulties.

Nevertheless, attempts to correct this imbalance have recently been performed, mainly including chromosomal analysis by *in situ* endonuclease digestion of two species of the genus Tenebrio (Coleoptera: Tenebrionidae) and banding chromosomal analysis of some species of scarab beetles (Coleoptera: Scarabaeoidea).

With the exception of few examples of G banding, chromosomes of Orthoptera have been studied by means of Ag and C banding.

In this work we characterize the karyotypic constitution of the grasshopper Anacridium aegyptium (Orthoptera: Catantopidae) by employing i) conventional Giemsa staining and ii) differential Ag, C, G, R and DAPI banding.

Obtained results can be summarized as follows:

- 1) males of A. aegyptium show a karyotype which is mainly constituted by euchromatin and consist of 23 chromosomes with a chromosomal sex determining mechanism of the XO O/XX ♀ type.
- 2) All spermatogonial metaphase chromosomes exhibit Ag-positive signals, terminally located near the centromerical region.
- 3) Complementarity between G and R banding patterns was not observed
- 4) Centromerical areas appear DAPI-positive, thus suggesting the occurrence of A+T base-rich DNA in these chromosomal regions.

Two main implications originate from data achieved in our study:

- 1) whether or not silver proteins occurring near the centromerical region of all spermatogonial chromosomes are related to a real presence of rDNA; and
- 2) whether or not the lack of complementarity between G and R euchromatic serial bands may be due to the inhibition of the trypsin activity as suggested for other species of insects.

SOME OBSERVATIONS ON MATING FREQUENCIES IN DROSOPHILA

S. Cakir, A. Kence

Biology Department, Middle East Technical University, 06531, Ankara, Turkey.

The objective of this study was to test the generality of frequency dependent fitness in mating behavior of Drosophila, called minority effect and to investigate the effect of artificial olfactory cues and marking the flies by wing clipping on the frequency dependent mate choice.

In the mating experiments, using wild-type (oregon) and mutant (white-eyed, sepia, ebony) strains of Drosophila melanogaster mating success of mutant males did not increase, as their frequency decreased. On the contrary, mating success of mutant males, especially that of white-eyed mutant males decreased as their frequency decreased. In the experiments to test the hypothesis that females behave according to concentration of olfactory cues in their environment in mate selection, and chose the rare males, the olfactory cue hypothesis was not supported. Marking by wing clipping had an adverse effect on the mating success of male flies. Deviations from random mating due to marking were statistically significant in D. melanogaster whereas in D. funebris, wing clipping did not produce significant deviations from random mating.

The results of this study does not support the contention that rare male advantage probably, is an important factor maintaining genetic variation in natural populations of Drosophila.

08-119

THE TRADE-OFF BETWEEN MIGRATORY ABILITY AND MATE ATTRACTION IN THE SAND CRICKET, *GRYLLUS FIRMUS*

D. A. Roff and P. Crnokrak

Department of Biology, McGill University, Quebec, Canada.

Wing dimorphism is common in many insect species. While it has been shown that in females there is a trade-off between fecundity and wing morph, the short-winged (flightless) morph having a higher fecundity, there is little information on the possible cost of being capable of flight in the male sex. In orthoptera males attract females by calling, an activity that is energetically expensive. We hypothesized that the energetic costs of maintaining wing muscles decreases the energy available for calling, thereby reducing the number of females a long-winged male can attract. We tested this hypothesis using the sand cricket, *G. firmus*. The hypothesis was confirmed, short-winged males calling almost twice as long as long-winged males, and attracting 75% of the available females. These differences were accentuated when energy was made limiting. Full-sib analysis demonstrated that the above phenotypic trade-off has a genetic basis.

08-121

SEASONAL PHENOTYPIC PLASTICITY OF LIFE-HISTORY TRAITS BETWEEN DIAPAUSE AND NON-DIAPAUSE GENERATIONS IN A MULTIVOTINE BRUCHID, *KYTORHINUS SHARPPIANUS*

M. Ishihara
Institute of Low Temperature Science, Hokkaido University, Sapporo, Japan

In *Kytorhinus sharpianus*, the diapause-generation adults cannot lay enough eggs without feeding, but show significant longer adult longevity and preoviposition period than non-diapause-generation ones. The longer the period of chilling during diapause, the more conspicuous this tendency.

I conducted a experiment using split-brood design, in which full-sib offspring of a parent were reared under either diapause (short day + chilling) or non-diapause (long day) conditions. ANOVA indicated both significant effects of environment (condition during rearing) and brood on adult longevity. In the number of eggs deposited, only an environment effect was indicated. However, this population did not show significant environmentXbrood interactions in both traits. These results illustrated phenotypic plasticity and small variations in the slopes of reaction norms. I discussed that the phenology of its host plant, *Sophola flavescens* would be most important to have evolved the phenotypic variation between the diapause and non-diapause generations in *K. sharpianus*.

08-120

INFLUENCE OF *DROSOPHILA* MALE WING SIZE ON THE COURTSHIP SOUND. R. Tidon-Sklorz, F.M. Sene¹.

Departamento de Biologia da Universidade de São Paulo, Ribeirão Preto, Brazil. 1. Departamento de Genética da Universidade de São Paulo, Ribeirão Preto, Brazil.

In the genus *Drosophila*, the sound pattern produced by the vibration of the males' wings, during courtship, is important as an auditory stimulus for conspecific recognition and successful mating. This work tested if the availability of food in the larval stage, which is an environmental factor that affects the size of the wing, will affect the courtship sounds of *Drosophila mercatorum pararepleta*. Fifteen females of *D. mercatorum pararepleta* were placed in a bottle with 30 ml of culture medium for two hours, and transferred to another bottle with 10 ml of medium, where they were maintained for 72 hours. In the first bottle the larvae had abundant food during development; in the second bottle the larvae were poorly fed. Morphometric analysis confirmed that adults well fed during development had larger wings than those from the poorly-fed environment. Statistical analysis of some sound parameters (interpulse interval and fundamental frequency) showed that the difference in wing size affected the sound involved in female sexual stimulation; however, it did not affect the sound which mediates species recognition. This shows that the size of the wing when changed by environmental influence although changes some sounds produced by the males does not interfere in the courtship sound related to species recognition

08-122

SHIFT IN PROPORTION BETWEEN PHENOTYPIC GROUPS IN *TRIBOLIUM* POPULATIONS AS THE REACTION TO ENVIRONMENT CONDITIONS

P. Bijok
Laboratory of Ecophysiology of Invertebrates, Institute of Ecology, Polish Academy of Sciences, Dziekanów leśny (near Warsaw), Poland

Intrapopulation diversity has been reported in two species of flour beetles: *Tribolium castaneum* Hbst. and *Tribolium confusum* Duval. Two phenotypic groups existing simultaneously within populations differ in number of larval instars, rate of development and body weight. Recent studies show differences in energy distribution, rate and cost of reproduction and other traits what suggests different life strategies in the two phenotypic groups.

The objective of the paper is to verify hypothesis that the observed diversity improves plasticity of the species. It can be done by checking whether the proportion of the groups in population can shift as the response to changes in environment conditions.

Synchronized cultures have been run in different conditions (population density, degree of medium conditioning, disturbance by older individuals or presence of other species). Distinguishing between the two phenotypic groups has been made on the basis of development time and body weight of pupae.

Obtained results showed that increasing medium conditioning and the influence of other individuals stocked in higher numbers raises the proportion of the group with slower development within population.

08-123

GENETIC BACKGROUND AND ENVIRONMENTAL DETERMINATION OF EGG SIZE OF A SKIPPER, *PARNARA GUTTATA GUTTATA* (Lepidoptera: Hesperidae)

F. Nakasuji, S. Fujioka, N. Nakahara

Faculty of Agriculture, Okayama University, Tsushima, Okayama 700, Japan

The rice skipper *P. g. guttata* has three generations a year and the adult of the second generation migrates to southwest direction in September in Japan.

The egg size of the skipper varies among the three generations, i.e. small, small and large. The size of eggs seems to be an adaptive trait in relation to the leaf toughness of host grasses in each generation. This seasonal variation of the egg size is determined by the daylength during the larval period of mother. The egg size has also genetic background. The larger female lays larger eggs. Heritability of the egg size was relatively high, 0.78, and a genetic correlation was found between the female size and egg size. Selection experiment for both adult size and egg size was conducted for more than 15 generations, and the large and small egg size lines were obtained for both selections. However, the phenotypic plasticity of egg size to the daylength of the selected lines was not different from that of the nonselected line.

08-124

FORMING A DIAPAUSE CLINE BY SELECTION

Sinzo Masaki

Laboratory of Entomology, Faculty of Agriculture, Hirosaki University, Hirosaki, Japan

In crickets, three different patterns of egg development are observed, corresponding to different climatic conditions: stable diapause in the temperate region, opportunistic diapause in the subtropics and virtual absence of diapause in the tropics. Within some of the temperate univoltine species, there is a variation in the intensity of egg diapause in parallel to the latitudinal temperature gradient. To test the possibility that such macrogeographic as well as microgeographic clines in diapause were established by selection in the process of expansion of the distribution over various climatic areas, diapause incidence (the percentage of diapause eggs at LD 12:12 and 25°C) and intensity (the duration of the egg stage) were selected in a subtropical population of the ground cricket *Dianemobius fascipes* collected from Ishigaki Island (24°N) near the southern end of the Ryukyu Arc. Four lines were thus established to select for egg stages of about 3, 8, 15, and 22 weeks, respectively. Both the incidence and intensity of egg diapause varied in response to selection over many generations, and these selected lines showed a graded series of variation. In the long diapause lines, the diapause character changed from the subtropical opportunistic type into a more stable temperate type of *D. nigrofasciatus*. Thus a diapause cline was experimentally produced. However, the percentage diapause did not reach 100% even after 10-20 generations of selection in any diapause-selected line, suggesting the involvement of a polygenic system in controlling egg diapause in this ground cricket.

08-125

MEADOW GRASSHOPPER AND ALTITUDE - AN ADAPTIVE PUZZLE

G. Köhler, J. Samietz, S. Bauer

Institute of Ecology, University of Jena, Germany

The morphometry and the colour polymorphism of *Chorthippus parallelus* (ZETTERSTEDT) were studied in 32 populations between altitudes of 300 m and 2.500 m above sea level in the Ore Mountains (field samples) and the Alps (collection Dr. Nadig, Switzerland). Despite of a considerable variation, the body size (hind femur) decreased with increasing altitude. Considering the distinctly shorter vegetation periods in the mountains, this coincides with laboratory results that smaller females reproduced earlier than greater ones due to energetical causes. With regard to the colour polymorphism of the populations, the percentage of darker morphs raised with increasing altitude. In field experiments significant differences up to 22 degrees between ambient temperature and body temperature of *Ch. parallelus*, depending on the amount of solar radiation energy, could be proved. But there is no clear correlation between the degree of melanism and the heat-up of individuals. The considerable heat-up of body temperature in dependence on insolation seems to be decisive for the completion of the life cycle and for reproduction of the species up to about 2.500 m above sea level at all.

08-126

THE SIMPLEST MEDIUM FOR REARING *DROSOPHILA MELANOGASTER*

D.I.Kotliarevskij

Laboratory of optimal aerosol application of pesticides. Institute of Chemical Kinetics and Combustion - Novosibirsk - Russia.

The author developed very simple and cheap rearing medium for fruit-fly *Drosophila melanogaster*. The medium consists of 30% of oat flour and 70% of water. The flour is put in the rearing tubes, then water is added. The tubes are closed with cotton plugs and are placed in the boiling water-bath for 45 minutes. After cooking, these tubes are dried a little in a drier (+80 - 100 C, 20-30 minutes), then they are cooled in the drier to the room temperature. This medium was compared with common medium, consisting of agar, yeasts, sugar and semolina. Several species of *Drosophila* were taken in the experiment, including wild-type and four mutant lines of *Drosophila melanogaster* (kindly given by Dr. I.K.Zakharov and Dr.B.F.Tchadov from the Institute of Cytology and Genetics, Novosibirsk, Russia). The mutant lines were reared on the medium, for at least 10 generations, and no deviations from the norm (as compared with common medium, mentioned above - it served as a control) in dimensions, development and fecundity were noticed. The proposed medium is free from expensive agar, sugar and yeasts (and it is not inoculated with yeasts). It is dense enough for flies. The residues of the medium are removed (during washing) not so easily, as in the case of agar-containing media, but the problem is solved by mechanical washers. Also the medium, composed of 5% of oat flour and 0,8-1% agar, is proposed.

D.I.Kotliarevskij, Russia, 630090, Novosibirsk-90, Institutskaja, 3, Institute of Chemical Kinetics and Combustion.

GENETICS OF COMPLEMENTARY SEX DETERMINATION: COUNTING SEX ALLELES IN *BRACON HEBETOR* (HYMENOPTERA: BRACONIDAE)

G.E. Heimpel¹, M.F. Antolin², M.S. Strand¹
¹Department of Entomology, University of Wisconsin, Madison WI 53706, USA. ²Department of Biological Sciences, Colorado State University, Fort Collins CO, USA.

We identified the sex alleles present in seven strains of *Bracon hebetor* that originated in various regions of the United States, and that had been cultured in the laboratory for various amounts of time. These alleles were then tested against *B. hebetor* populations available from commercial insectaries.

Within- and among-strain crosses to identify shared or divergent alleles were conducted using the production of diploid male offspring as a criterion indicating shared alleles in a cross. For some crosses, mutant phenotypic markers that segregate independently of the sex allele were available for identification of diploid males. For other crosses, however, such markers were not available, and the production of diploid males was confirmed using a combination of offspring survivorship data, sex ratio data, and karyotypes.

The survivorship of diploid male eggs was low when relative humidity was low, and higher when relative humidity was high. Also, mortality of diploid male eggs skewed the secondary sex ratio in predictable ways. We therefore compared the survivorship and secondary sex ratio of broods from crosses that were reared at either low or high levels of relative humidity. To compare secondary sex ratios with the fertilization rate, egg karyotypes were taken from complete broods. Finally, the production of diploid males was confirmed by karyotyping male pupae.

TRACKING THE EVOLUTIONARY HISTORY OF APOSEMATISM - EXPERIMENTS IN A NOVEL WORLD

R. V. Alatalo, J. Mappes

Department of Biological and Environmental Science, Konnevesi Research Station, University of Jyväskylä, P.O.Box 35, FIN-40351 Jyväskylä, Finland

It is very hard to study the initial origin of aposematism, where unprofitable prey signal their unprofitability. After the long evolutionary history that predators have faced with aposematic prey items, it is difficult to unravel any inherited avoidance of common or conspicuous warning signals. Inherited effects do not only appear as immediate reluctance to attack aposematic prey, they may also enhance the avoidance learning or induce cautiousness of the attacks allowing the prey escape unharmed. To overcome the evolutionary history in the response of predators against warning coloration we created a novel world without colours using artificial symbols both in the background and as the signals. A series of experiments with great tits demonstrated that, initially, prey aggregation would have favoured the prey that signal their unpalatability. However, the clear advantage of clumping seems to disappear once birds have experience of similar warning signals. This context, representing Müllerian mimicry in a broad sense, is the situation where most of the unpalatable prey have evolved their warning signals. Previous experience enhances the learning by predators to avoid any new aposematic prey, even if the prey were solitary.

08-128

ALLOZYME SURVEY ON POPULATIONS OF *EUREMA HECABE* L. FROM JAPANESE MAIN AND SOUTHWEST ISLANDS (LEPIDOPTERA: PIERIDAE)

M. Nomura and Y. Kato¹

Faculty of Horticulture, Chiba University, Matsudo, Chiba, Japan - ¹ Department of Biology, International Christian University, Mitaka, Tokyo, Japan

The pierid butterfly, *Eurema hecabe* L., distribute widely in Japan and Southeast Asia. The populations in Okinawa and Ishigaki Islands showed some differences from the Main Is. population in its seasonal forms of the adult wing and in host plant preferences of larva.

We analyzed allozyme survey for populations from the Main Is. (Honshu, Shikoku and Kyushu), Okinawa Is. and Ishigaki Is. of Japan using a technique of the polyacrylamide gel electrophoresis. Obtained zymograms and allele frequencies of 15 loci were different among these populations, although they belong to a single subspecies *Eurema hecabe hecabe* in the present taxonomic status.

The allozyme data of the "Honshu-form" adults (which shown a wing pattern of Honshu type) collected in Okinawa Is. also different from the "Okinawa-form" butterflies, and they showed a close similarity to populations from main islands.

We will discuss the origin of "Honshu-form" butterflies on the basis of molecular, ecological and physiological aspects.

08-130

COLOR POLYMORPHISM IN THE HAWAIIAN HAPPY-FACE SPIDER, *THERIDION GRALLATOR* (ARANEAE: THERIDIIDAE): GENETIC MODIFICATION AND THE COUNTER ROLE OF SELECTION.

R.G. Gillespie, G.S. Oxford¹

Center for Conservation Research and Training, University of Hawaii, Honolulu, HI, USA - ¹ Department of Biology, University of York, York, UK.

The Hawaiian happy-face spider, *Theridion grallator*, an endemic to four islands in the Hawaiian archipelago, exhibits an exuberant color and pattern polymorphism involving both the carapace and opisthosoma (abdomen). Laboratory crosses, and broods from wild-mated females, demonstrate that the opisthosomal morphs on Maui (and probably on Moloka'i as well) act as if they are determined by alleles at one autosomal locus, although control by more than one linked locus cannot be eliminated. All morphs are found equally in males and females. In contrast, on Hawai'i Island, the 'yellow' and 'red front' morphs are controlled by a single allele, sex-limited in expression, such that females are 'yellow' and males 'red front'. 'Red blob' and 'red ring' form a similar pair of morphs, with 'red blob' confined to females, 'red ring' to males. In addition, there appear to be two unlinked loci involved in determining the color polymorphism on Hawai'i. The island-wide sex-limitation of 'yellow' and 'red front' suggests that the quantum shifts in the genetic control of the polymorphism among islands probably trace their origins to the founding event when *T. grallator* colonized Hawai'i from Maui.

Among color morphs, the relative frequency of morphs is remarkably constant among populations. $F_{ST}(\theta)$ values calculated using electrophoretic loci were much higher than those calculated using color morph alleles. This observation is consistent with selection operating to maintain the color alleles. We have suggested that bird predators are the most likely selective agent because of their ability to modify their feeding effort according to the frequency of a morph.

08-131

SPECIES PHYLOGENY OF THE BEE GENUS *EXONEURELLA* (HYMENOPTERA: APIDAE: ALLODAPINI) BASED ON MORPHOLOGICAL AND MOLECULAR DATA SET

S.G. Reyes and M.P. Schwarz

School of Biological Sciences, The Flinders University of South Australia, GPO Box 2100, Adelaide 5001, South Australia.

The members of the bee genus *Exoneurella* exhibit a range of social behavior from almost solitary to highly eusocial. *Exoneurella* forms the basal group for the rest of the endemic Australian allodapine bees, the *Exoneura* group. A cladistic analysis of the species relationships of the genus *Exoneurella* using morphological characters and sequenced data from cytochrome oxidase b of mtDNA was undertaken. Each data set analyzed separately gave slightly differing results. Morphological analysis using 41 adult, egg and larval characters resulted in one tree with minimal homoplasy and with the following species relationship: tridentata + (lawsoni + (eremophila + setosa)). Both strands of cyt b of the mtDNA were sequenced for the outgroup *Brevineura* and the *Exoneurella* species. Sequenced data analysis based on 383 bp of cyt b yielded one tree with higher homoplasy index than one based on morphological data set and with the following species relationship: tridentata + (setosa + (eremophila + lawsoni)). When morphological and molecular data were combined and analyzed, the resulting cladogram resembles the cladogram based on the morphological data set. The importance of historical patterns in looking at social evolution will be briefly discussed.

08-132

THE MOLECULAR PHYLOGENY OF MOSQUITOES IN ANOPHELINEAE AND CULICINAE (DIPTERA: CULICIDAE) BASED ON THE MITOCHONDRIAL GENE, CYTOCHROME C OXIDASE SUBUNIT II.

C.M. Ho, Y.M. Liu, C.C. Chen, C.C. Wu

Department of Parasitology, National Yang-Ming University, Taipei, Taiwan, Republic of China

With the polymerase chain reaction (PCR) and versatile primers that amplified the whole gene of cytochrome c subunit II (COII), we obtained 7 complete gene sequences represented three genera in Family Culicidae. These mosquitoes were *Anopheles sinensis*, *A. minimus*, *Aedes albopictus*, *A. togoi*, and *A. alsiaticus*, *Culex tritaeniorhynchus* and *C. annulus*. Together with other published sequences of four species, *A. gambiae*, *A. quadrimaculatus* and *A. aegypti*, and *C. quinquefasciatus*, provided a total of eleven mosquitoes sequences. This allowed a comparison of genes with a wide range of divergence. The comparison permitted an assessment of the phylogenetic relationships. In all cases, a single DNA fragment was obtained verified to a COII gene by Southern hybridization. These fragments were 685 bp in length. The deduced amino acid based on the nucleotides were 288 residues in length, beginning with conserved initiation methionine codon and terminating with an incomplete stop codon of T. Among these species nucleotide similarity ranged 81-99%, identity of deduced amino acid ranged 85-100%. The neighbor-joining trees based on the divergence of nucleotides and amino acids revealed the similar of branches.

08-133

MITOCHONDRIAL DNA EVOLUTION IN *DROSOPHILA IMMIGRANS* SPECIES GROUPS. C. Tsaur, C. T. Ting¹, S. Fang^{1,2}, F. J. Lin²

Department of Ecology and Evolution, The University of Chicago, Chicago, IL USA - 1 Department of Plant Pathology and Entomology, National Taiwan University, Taipei, R.O.C. - 2 Institute of Zoology, Academia Sinica, Taipei, R.O.C.

The inferring phylogeny of *Drosophila nasuta* species subgroup of *D. immigrans* species group based on mtDNA as well as morphometric analysis has been compared in our previous studies. Despite the concordance lies between those two approaches, the mtDNA alone, however, shows some variations which including restriction site changes and size differences providing more information about the evolutionary process among these closely related species rather than morphological differentiations do. We report here the sequences of the mitochondrial cytochrome oxidase II gene of 25 species in the *D. immigrans* species group. This survey includes 5 members of the *D. hypocausta* subgroup, 3 of the *D. immigrans* subgroup, 14 of the *D. nasuta* subgroup, and 2 of the *D. quadrilineata* subgroup. The COII gene in this species group is 688 nucleotides in length as long as the *D. obscura* species group does, but 3 nucleotides longer than those of *D. melanogaster* and *D. yakuba*. The A+T content is high and show a strong transition bias as other *Drosophila* species do. The phylogenetic relationships in the species group are inferred using both neighbor-joining and maximum parsimony. The information provided by this sequence is in agreement with almost all other molecular and morphological data and suggested that the *D. nasuta* subgroup is a monophyletic group in *D. immigrans* species group. Furthermore, the size differences region of *D. immigrans* species will also be discussed.

08-134

EVOLUTION OF POLLEN FEEDING IN *HELICONIUS* BUTTERFLIES (LEPIDOPTERA: NYMPHALIDAE)H.W. KRENN¹, C.M. PENZ²¹Institute of Zoology, University of Vienna, Austria²Department of Zoology, University Texas Austin, USA

The neotropical *Heliconius* butterflies use their proboscis in addition to nectar feeding for the external collection of pollen and the subsequent uptake of the extracted amino acids (Gilbert LE 1972, Proc Nat Acad Sci USA 69: 1403-1407). Although this unique behavior has a central role in the biology of this group of Nymphalidae, the proboscis morphology and the pollen feeding behavior was not investigated in detail so far.

In order to reconstruct the evolution of this key innovation, the proboscis of 20 species of pollen feeding and non-pollen feeding Heliconiini was compared by means of light and scanning electron microscopy. The proboscis movements during flower visits and the pollen processing behavior were recorded in several species in the green house.

The morphological investigation did not show additional structures that exist exclusively on the proboscis of pollen feeders. However the comparison with non-pollen feeders revealed the reduction in the relative length of the proboscis tip, the modification of the length of sensilla, and a shift in the time pattern of proboscis movements. This distinct combination of features can be functionally interpreted in context with the collection and processing of pollen.

The evolution of pollen feeding and the implications for the systematical relationships in Heliconiini is discussed in reference to the features of the mouthparts and recent molecular data.

08-135

PHYLOGENIES DERIVED FROM NUCLEAR AND MITOCHONDRIAL GENES: COPING WITH PROBLEMS OF INCONGRUENCE, ALIGNMENT, AND INTRASPECIFIC VARIATION IN *ANOPHELES* MOSQUITOES

J.A. Danoff-Burg¹ and J.E. Conn²

Department of Biology, University of Vermont, Burlington, VT 05405 - 1 Jdanoffb@Moose.UVM.edu - 2 Jconn@Moose.UVM.edu

Phylogenetic trees with conflicting topologies are frequently produced when phylogenies are constructed using multiple molecular data matrices. We present the results of a series of phylogenetic analyses using 380 bp of the nuclear *ITS 2* and 690 bp of the mitochondrial *COII* gene for 21 species in the *Anopheles* subgenus *Nyssorhyncus* and four outgroup species. When analyzed separately, each gene gave a slightly divergent phylogeny. We advance an incongruence metric for measuring disagreement between phylogenies.

Although alignment problems and intraspecific variation were not present in the *COII* gene, both were abundant in the *ITS 2*. Intraspecific variation within *ITS 2* was present in over 24% of the ingroup species. Alignment ambiguities due to multiple gap insertion prompted us to experiment with differential gap penalties and multiple alignments for *ITS 2*. Each alignment was then independently analyzed phylogenetically.

A phylogenetic hypothesis is advanced that includes both genes, but downweights *ITS 2* sites when they conflict with the *COII* phylogeny. This phylogeny greatly differs from a previous one based on morphological characters.

08-137

GENETIC STRUCTURE OF *OOPTERUS SOLEDADINUS* (COLEOPTERA, TRECHIDAE) SINCE ITS RECENT INTRODUCTION AT THE SUBANTARCTIC KERGUELEN ISLANDS.

M. Chevrier¹, P. Vernon¹, J. Deunff², P. Tréhen¹

CNRS (URA 1853), Université de Rennes 1, ¹ Lab. d'Ecologie du Sol et de Biologie des Populations, Station Biologique de Paimpont, F-35380 Paimpont (France). ² Lab. de Parasitologie Pharmaceutique, 2 av. du Pr L. Bernard, F-35043 Rennes Cedex (France).

Oopterus soledadinus is a wingless predaceous beetle native from South Patagonia and Falkland Islands (51° 50' S). This species was accidentally introduced in 1912 at Port Couvreur on Kerguelen Islands (Southern Indian Ocean, 49° 20' S). Since its introduction, it only spread on littoral zone along the archipelago. Currently, it has colonized most of the eastern part of the Grande Terre (main island of the archipelago) with a maximal distance of 106 km from the introduction site.

We study genetic structure and morphometric features of three populations of *O. soledadinus* in order to describe their potential isolation. The reference population was sampled at the introduction site (Port Couvreur), the second one came from a littoral site 48 km away from Port Couvreur. Beetles from the third population were collected at the north side of Ile Haute (39 km away from Port Couvreur). The last two sites were selected owing to their distance from introduction site and to the kind of geographic isolation of the third one (sound). Eleven morphometric parameters were measured on both sexes of beetles from each population and several polymorphic allozyme loci were studied after carrying out a screening of proteins on the third population.

The colonization way of *O. soledadinus* is dependent on the interaction between its dispersal regime (flightlessness), its ecology (littoral species) and the occurrence of physical barriers. Did these features affect the genetic structure of this newly introduced species?

08-136

Cloning of microsatellites for parentage analysis and population studies in *Leptothorax* ants.

H.A.A.Green, M.W.Bruford, A.F.G.Bourke.
Institute of Zoology, Zoological Society of London,
Regent's Park, London NW1 4RY

A set of highly polymorphic microsatellite markers were developed for parentage analysis in multiple-queened colonies of *Leptothorax acervorum*.

When tested on a group of unrelated individuals they showed levels of heterozygosity ranging from 40-95%. To date one locus has yielded 44 alleles, ranging in size from 198-360 bp. The relationship between sequence composition and genetic variation among these diverse di-, tri- and tetranucleotide microsatellites will be discussed. These markers have been adapted for application on an ABI 373 automated sequencer, which allows for the multiplex amplification and electrophoresis of as many as 15 loci per individual. Our approach to this application will be discussed.

Finally, population genetic analysis of *L.acervorum* was carried out on a European-wide scale using the above markers. Results are discussed.

08-138

POLYMORPHISM IN PHOSPHOGLUCOMUTASE (PGM) AND HEXOKINASE (HK) IN *Apis mellifera* L. IN TURKEY

İrfan Kandemir, Gaye Kandemir, Meral Kence, Aykut Kence

Middle East Technical University, Department of Biological Sciences
Ankara-Turkey

We have investigated Phosphoglucumutase (PGM) and Hexokinase (HK) enzyme systems electrophoretically in *Apis mellifera* L. from samples collected in 16 localities over Turkey. Four alleles of PGM system were found. They were named as 100, 75, 63, and 45 according to their relative mobilities. This is the first report of four alleles found together in one study. Pgm-100 and Pgm-75 alleles were found in all localities. Gene frequencies of the most common allele (Pgm-75) ranged between 0.583-0.929. The Pgm-63 allele was found consistently in southern localities and the Pgm-45 was recorded only in one location from north-west of Turkey.

Three alleles of HK were found. They were named as 88, 100 and 110 according to their relative mobilities. HK-100 was the most common allele and found in all localities. The gene frequencies of this HK allele (HK-100) ranged between 0.679-0.992. HK-88 and HK-110 were the rare alleles and were found only in seven and six localities respectively.

08-139

POPULATION GENETIC STRUCTURE OF THE "JETHYS" COMPLEX OF *ENANTIA* (LEPIDOPTERA: PAPILIONOIDEA; PIERIDAE).

A. Castañeda, D. Piñero.

Departamento de Ecología Evolutiva, Centro de Ecología. Universidad Nacional Autónoma de México. Distrito Federal. México.

Genetic structure and variation was studied in Mexican populations of three species that constitute the "jethys" complex of *Enantia* (Lepidoptera: Papilionoidea; Pieridae). These species have contrasting geographical distributions. *Enantia albania* and *E. mazai* have a wide distribution while *E. jethys* has a more restricted distribution. Twelve populations of *E. albania*, 9 of *E. mazai*, and 3 of *E. jethys* were studied for 10 enzyme loci. All three species have approximately the same number of alleles per locus (2) and high average heterozygosities (0.156-0.358). *E. albania* and *E. jethys* populations present allelic homogeneity due to high gene flow levels ($F_{ST}=0.096$ and $F_{ST}=0.044$ respectively). *E. mazai* populations have a greater genetic structuring ($F_{ST}=0.2325$). In this species, gene flow between population pairs (average $Nm=8.345$) is inversely related with the geographical distance between populations according to an isolation by distance model. This last result is consistent with the pattern expected for species in Hardy Weinberg equilibrium where gene flow is exclusively between adjacent populations.

08-140

POPULATION GENETICS OF EUROPEAN SALT MARSH CARABID BEETLES STUDIED BY ENZYME AND DISPERSAL POLYMORPHISM AT DIFFERENT SPATIAL SCALES

K. Desender¹, K. Delahaye², Th. Backeljau¹

¹ Royal Belgian Institute of the Natural Sciences, Brussels, Belgium - ² State University Ghent, Belgium

We study population genetics of invertebrates in the framework of nature conservation. This case study reports on enzyme and dispersal polymorphism in the halobionth carabid beetles *Pogonus chaldeus* (Marsham) and *Dicheirotichus gustavii* (Crotch). The species are studied at different levels of spatial scale, in populations with varying size and isolation, in the remaining salt marshes in Belgium and reference sites at larger distance (France, U.K. and the Netherlands). Enzyme polymorphisms are studied by cellulose acetate gel electrophoresis. Dispersal polymorphism is studied by investigation of wing and flight muscle development.

Based on enzyme polymorphism, *D. gustavii* shows a larger genetic variation and, being the species with a relatively higher dispersal power, an expected smaller genetic differentiation between populations. Clear relationships between population or site characteristics and genetic structure are not observed, except for the special position taken by some small populations in both species. Concordant to these observations, the dispersal power of *P. chaldeus* in these small populations is larger, also leading to the conclusion that these populations are unstable and/or very young. They are however not always showing a lower genetic diversity as would be expected as a result of genetic drift in small populations.

Dispersal power in *P. chaldeus* declines with increasing age of salt marsh, probably due to a continuous emigration of winged individuals. The only exception relates to a population from Mont St. Michel (France) and is tentatively explained by the very large area of its salt marshes.

Age and size of salt marshes, although difficult to study independently, both appear to be important for the genetic structure of halobionth beetles. A maximal diversity in both parameters is therefore recommended as an optimal nature conservation strategy.

08-141

GENETIC STRUCTURE OF HOST ASSOCIATED POPULATIONS OF *YPONOMEUTA PADELLUS* (YPONOMEUTIDAE, LEPIDOPTERA): DO ALLOZYMES AND RAPDS TELL THE SAME STORY?

L.E.L. Rajimann, J.C. Wientjes, W.N. Ellis, S.B.J. Menken

Institute for Systematics and Population Biology, University of Amsterdam, Amsterdam, The Netherlands

Patterns of allozyme and Random Amplified Polymorphic DNA (RAPD) variation were used to estimate within and among population differentiation and levels of gene flow in *Crataegus* spp. and *Prunus cerasifera* infesting populations of the oligophagous small ermine moth, *Yponomeuta padellus*. A recently developed theory for the analysis of population structure with dominant RAPD markers was used to compare RAPD results with those obtained from allozyme analysis; both techniques were applied to exactly the same set of individuals. Allozyme frequencies differed significantly at 24 % of all polymorphic loci (19 in total) among all *Crataegus* populations, and at 31 % between the allopatric *P. cerasifera* populations. The number of loci with significantly different allozyme frequencies between populations on either hosts at two localities was 57 % and 50 %, respectively. The amount of gene flow, indicated by values of \hat{M} (i.e. the number of individuals exchanging per generation), between the sympatric *Crataegus* spp. and *P. cerasifera* populations was estimated at 1.9 and 2.2, respectively. These values were both considerably lower than the mean \hat{M} value of all pairwise comparisons of five allopatrically located *Y. padellus* populations on *Crataegus* spp. The RAPD data, however, did not corroborate these results. The estimates of population subdivision with RAPD markers, for example was much more pronounced than with allozymes and RAPD frequencies varied considerable among populations. We due these conflicting results to selection on the allozyme polymorphisms whereas the RAPDs are considered as neutral markers.

08-142

ALLOZYME VARIATION AND GENETIC STRUCTURE OF *CHIRONOMUS RIPARIUS* POPULATIONS FROM METAL CONTAMINATED AND NON CONTAMINATED SITES

L.E.L. Rajimann, I. van Grootveld, S.B.J. Menken, N.M. van Straalen

Institute for Systematics and Population Biology, University of Amsterdam, Amsterdam, The Netherlands

Saprotrophic arthropods are exposed to a large number of potentially toxic chemicals due to pollution of their natural habitat. Among these chemicals, contamination by heavy metals is an obvious example since they accumulate in soils and sediments. Because of their toxicity and persistence, contamination by heavy metals is a good example of how natural selection acts in nature. We therefore studied allozyme variation patterns to estimate within and among population differentiation of the midge *Chironomus riparius*. Populations from metal contaminated and non contaminated sites were sampled in the Dommel, a river system on the border of Belgium and the Netherlands with very high levels of copper and cadmium concentrations. Two indirect methods of estimating average gene flow levels were applied, i.e. Wright's *F*-statistics and the private allele method. Preliminary results showed that pollution by heavy metals do affect the population genetical structure of *C. riparius* populations. Nevertheless, it was also found that the geographical component was an even more important factor in shaping the genetical population structure. Since this can be the results of the fact that the genetic markers used in this study were not under the direct influence of natural selection or to loci linked by them, the number of genetic markers will be increased in the present future.

MODULATION AND TRANSDUCTION OF THE PHEROMONOTROPIC RESPONSE TO PBAN
A. Rafaeli C. Gileadi
Department of Stored Products, ARO, The Volcani Center, Institute for Technology & Storage of Agricultural Products, P.O. Box 6, Bet Dagan, Israel.

Pheromone production by many moth species is regulated by the timely release of pheromone biosynthesis activating neuropeptide (PBAN) which signals the induction of pheromone production by female moths. Our *in vitro* studies¹ on *Helicoverpa armigera* have resulted in the identification of the target cells for neuropeptide action. These cells are situated in the intersegmental tissue between the 8th and 9th abdominal segments of female moths. No pheromonotropic activity was observed in incubations of the 8th segment alone. The neurotransmitter, octopamine and its analogs, tyramine and clonidine, were observed to inhibit and modulate the pheromonotropic action due to PBAN. The biochemical second messenger system during both pheromonotropic (PBAN) and pheromonostatic (adrenergic agonists) activities was studied. Several second messengers (cAMP, calcium and phosphatidylinositols) were implicated as transducers of PBAN action². The ionophores, ionomycin and thapsigargin, stimulated both pheromone biosynthesis and intracellular cAMP production. Both activities (pheromone and intracellular cAMP production) were inhibited by calcium-calmodulin inhibitors (W12 & W7). The involvement of G-proteins was implicated by the calcium-dependent stimulatory action of NaF (1mM), which, like PBAN, stimulated both pheromone biosynthesis and intracellular cAMP production. This stimulatory action was significantly inhibited by adrenergic agonists and was reversed in the presence of pertussis toxin thus implicating G_i in the modulation of pheromonotropic activity. From our studies we conclude that a negative regulation of pheromone biosynthesis occurs at the membrane receptor level by the interaction of an adrenergic receptor with the PBAN receptor.

SPATIOTEMPORAL ASPECTS OF CALCIUM SIGNALLING

Michael J. Berridge, Babraham Institute Laboratory of Molecular Signalling, Department of Zoology, University of Cambridge, Downing Street, Cambridge CB2 3EJ.

Cells employ both external and internal sources to generate Ca²⁺ signals which are often organized in complex spatial and temporal patterns. Many stimuli use inositol 1,4,5-trisphosphate (InsP₃) to control both the release of internal Ca²⁺ and the influx of external calcium. Opening of the InsP₃ receptors on the endoplasmic reticulum is controlled by both InsP₃ and Ca²⁺ and this dual regulation forms the basis of a model to explain both Ca²⁺ spiking and Ca²⁺ waves. Continuation of this oscillatory cycle is often dependent upon the influx of external Ca²⁺. Particular attention will be focused on the processes of capacitative Ca²⁺ entry which is regulated indirectly by InsP₃ through its ability to empty the Ca²⁺ stores. Recent work in *Xenopus* oocytes and *Drosophila* photoreceptors have characterized both the kinetics of this entry process and its sensitivity to Ca²⁺. The results are discussed in relation to a conformational coupling mechanism whereby the head of the InsP₃ receptor is responsible for transferring information from the E.R. to the plasma membrane.

Calcium entering from the outside is then taken up by the internal stores from which it is released periodically as Ca²⁺ spikes. The initiation processes seem to depend upon the integration of unitary Ca²⁺ events which have been referred to as bumps, sparks and puffs. Co-ordination of these unitary events, often achieved through the regenerative processes of Ca²⁺-induced Ca²⁺ release (CICR), results in the global Ca²⁺ signals responsible for cell activation.

09-003

ROLE OF CALCIUM AND PHOSPHOINOSITIDES IN THE REGULATION OF JUVENILE HORMONE BIOSYNTHESIS IN COCKROACHES

S.S. Tobe¹ and A. Rachinsky²
¹Department of Zoology, University of Toronto, Toronto, ON CANADA
²Zoologisches Institut, Universität Tübingen, Tübingen, GERMANY

Juvenile hormone (JH) biosynthesis is regulated by peptidergic inputs. Depending upon the species and developmental stage, these signals may be either inhibitory or stimulatory (allatostatins and allatotropins). Signal transduction within corpus allatum cells occurs by way of known second messengers, including the cyclic nucleotides, calcium and the phosphoinositides. In the cockroach, *Diploptera punctata*, allatostatic signals appear to be the principal regulators of JH production. Receptors for allatostatins have been partially characterized from brain and corpus allatum of *D. punctata*. These receptors probably differ between tissues and probably occur as distinct sub-types, which may be a function of the large number of allatostatins and their wide range of actions.

Modulation of intracellular calcium levels by drugs (ionophores, calcium chelators and releasing agents, calcium channel blockers) or depolarizing agents, including current injection, dramatically alters JH biosynthesis, as do agents that activate the phosphoinositide pathway. Allatostatins also appear to directly affect calcium flux in corpus allatum cells. Modulation of intracellular cAMP levels is associated with changes in JH production, with increases in JH biosynthesis occurring as a consequence of the stimulation of the adenylate cyclase system in some species (e.g. locusts) but with an inhibition of JH biosynthesis in cockroaches. The effects of second messengers differs between species, probably as a consequence of the differences in the peptide signals that regulate JH biosynthesis and in the intrinsic state of the corpora allata (either switched on or switched off, in the absence of external signals).

NITRIC OXIDE: A NEW SIGNALLING MOLECULE IN THE INSECT CNS

Michael O'Shea, Maurice Elphick¹

Sussex Centre for Neuroscience, School of Biology, University of Sussex, Brighton BN1 9QG, UK; ¹ School of Biology, Queen Mary & Westfield College, University of London E1 4NS, UK

Nitric oxide (NO) is now recognised as a neuronal signalling molecule in the mammalian brain. NO is synthesised in nitrergic neurons by a Ca²⁺-calmodulin activated nitric oxide synthase (NOS) which catalyses the conversion of L-arginine and molecular oxygen to NO and citrulline. NO activates the enzyme soluble guanylyl cyclase (sGC) producing the second messenger cGMP.

We have demonstrated the existence of the NO cGMP signalling pathway in the insect CNS. The optic lobes show extensive and locally intense staining using the NADPH diaphorase technique. NOS is also associated with local interneurons in the olfactory lobes where NOS staining in fibres defines the glomerular organisation. An association between the NO and learning and memory is suggested by entirely new and unexpected structures within the mushroom bodies. The α and β lobes of the mushroom bodies contain tubular structures defined by strong circumferential NOS staining. These are the first sub-compartmental structures to be described in the mushroom bodies, parts of the insect brain associated with learning and memory. Biochemical and molecular studies indicate the presence in the insect CNS of the two principal enzymatic components of the signalling pathway, namely NOS and sGC, with considerable sequence identity with their mammalian counterparts. This talk will review our progress towards understanding the molecular biology, cellular localisation and functional role of this signalling pathway in the insect brain. Grant BBSRC GR/J33234.

09-005

INTERCELLULAR SIGNALLING AND THE REGULATION OF CELL DIVISION IN THE MALPIGHIAN TUBULES OF *Drosophila melanogaster*

Helen Skaer, Alexandra Gampel and Susan Wan.

Department of Anatomy, University of Oxford, South Parks Road, Oxford OX1 3QX

The excretory system of the fly consists of four Malpighian tubules, which arise from the embryonic hindgut by eversion of primordial cells. Cell proliferation in each of the four primordia is completed during a short period of embryogenesis. The pattern of cell proliferation is precise and reproducible. We have identified components of the regulatory network governing cell division and shown a requirement for the activity of two signalling pathways: one mediated by *wingless* and the other by *spitz*, through the activation of the *Drosophila* EGF receptor (DER). In addition, the activity of a single cell in each tubule, the tip cell, is required. The phenotypes of the Malpighian tubules in embryos mutant for elements of the signalling pathways and those in which the normal specification and differentiation of tip cells is perturbed, indicate that the combination of triggers that stimulate cells to divide change during tubule development. The relationship between these regulatory factors and the passage of responding cells through cell cycle checkpoints is currently being investigated.

09-006

BETWEEN PEPTIDE HORMONE AND STEROID HORMONE: THE PTTH TRANSDUCTORY CASCADE.

R. Rybczynski

Department of Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC USA

Ecdysteroids coordinate molting and metamorphosis of insects. In pre-adult Lepidoptera, the prothoracic glands produce ecdysteroids, under the acute control of the brain neuropeptide prothoracicotropic hormone (PTTH). In the 1980s, *in vitro* studies, using the model insect *Manduca sexta*, indicated that PTTH stimulates rapid intracellular increases of Ca²⁺ and cAMP in prothoracic glands. More recent studies demonstrate that changes in these intracellular second messengers are followed rapidly by prothoracic gland-specific changes in the phosphorylation state of at least 1 protein (the ribosomal protein S6) and the rapid synthesis and accumulation of 3 to 6 proteins (including β tubulin and the heat shock protein, hsc 70). This suite of intracellular events appears to be required to support the rapid increase in ecdysteroid synthesis that normally accompanies PTTH stimulated, possibly by controlling the rate of movement of ecdysteroid precursors among intracellular compartments. Some of these molecules may also play a long term role in modulating the growth (size) of prothoracic gland cells, and by doing so, effectively set upper and lower limits on ecdysteroid production by PTTH-stimulated and unstimulated (resting or basal) glands, respectively.

09-007

THE OVARIAN INSULIN RECEPTOR - A POTENTIAL ROLE IN THE REPRODUCING MOSQUITO

R. Graf, P. Helbling, M.R. Brown¹, U. Ackermann, S. Neuen-schwander; Zoologisches Institut, Universität Zürich, Zürich, Switzerland, ¹Dept. Entomology, University of Georgia, Athens Ga. USA

When the female mosquito, *Aedes aegypti*, takes a blood meal, a cascade of hormonal events is initiated which maintains vitellogenesis and oocyte maturation. The major hormone(s) with gonadotropic action, the ovarian ecdysteroidogenic hormone (OEH), induces ovarian ecdysteroidogenesis directly and vitellogenesis indirectly. In some insects, ecdysteroid secretion has been linked to the presence of insulin-like material and we have found that vertebrate insulin stimulates this process in mosquito ovaries *in vitro*.

In vivo, ovaries increase their protein synthesis rate several-fold after activation by a blood meal, making protein synthesis a simple indicator for the activation state of the ovary. In an *in vitro* protein synthesis assay we demonstrated that insulin can induce a two to three fold increase in previtellogenic ovaries. Based on this lead, we have proposed that insulin receptors transduce hormonal signals for ecdysteroidogenesis in the mosquito ovary. By sequence homology, we have designed PCR-primers to synthesize fragments coding for conserved subdomains of tyrosine kinases. One such fragment was used to clone cDNAs from ovaries. An open reading frame (mosquito insulin receptor, MIR) shows the typical characteristics of a receptor tyrosine kinase: a cysteine-rich extracellular domain, a processing site for precursor cleavage into α - β -subunits, a transmembrane domain in the β -subunit followed by consensus sequences for tyrosine kinases. Expression analysis of mRNA indicated a highly specific accumulation of MIR-mRNA in ovaries. *In situ*-hybridization demonstrated expression in the nurse and follicle cells before and after a blood meal. Towards the end of the egg maturation process, a decrease of MIR-mRNA was observed along with the degeneration of follicle cells. Immunocytochemical detection of MIR demonstrated a colocalization with MIR-mRNA.

Our observations support the conclusion that the mosquito insulin/insulin receptor homologs play a crucial role during egg maturation.

09-008

INDEPENDENCE OF HOST FACTORS MAY EXPLAIN THE WIDESPREAD DISTRIBUTION AND HORIZONTAL TRANSFERS OF *MARINER* TRANSPOSONS

H. M. Robertson, D. J. Lampe

Department of Entomology, University of Illinois, Urbana, IL USA

Mariner transposons have been shown to be extremely widespread in animals. In addition to the many hundreds of representatives identified in diverse insects, they have been found in mites, flatworms, hydras, and primates. They can be organized into five major subfamilies, and at least twelve additional smaller subfamilies. *Mariners* are related to the *Tc1* family of transposons also found widely in animals, and more distantly to a diverse superfamily of transposons such as IS630, IS3, Tn10 and Mu bacteriophage, as well as the integrases of retroviruses. These transposases share a conserved D,D35E catalytic domain, and catalyse transposition by a cut-and-paste mechanism.

The evolutionary relationships of *mariner* transposons clearly demonstrate that particular elements have been transferred horizontally between hosts, both recently and anciently. Sometimes these hosts are in different orders of insects or even phyla of animals. These observations suggest that they can function independently of host factors. We have developed an in vitro transposition assay for an irritans subfamily *mariner* from the horn fly, *Haematobia irritans*, called *Himar1*, in which transposition of a marked element between plasmid substrates is catalysed by purified transposase protein. These results are similar to those obtained for retroviral integrase, and may apply to most members of the superfamily, indicating that host factors are not required for transposition.

Several attempts to obtain activity of *Himar1* in *Drosophila melanogaster* as a test system have failed, but we continue to test this construct as well as other *mariners* for activity in this fly in preparation for development as genetic tools for other insects. Given their wide distribution and independence from host factors, various *mariners* may prove to be useful genetic tools in other animals too. It remains to be seen, however, whether organisms have "defences" against transposable elements that might limit the host range of particular *mariners*.

HAT TRANSPOSABLE ELEMENTS AS GENE VECTORS IN INSECTS.D. A. O'Brochta and P. W. Atkinson¹

Center for Agricultural Biotechnology, University of Maryland, College Park, Md, 20742, USA - ¹ CSIRO Division of Entomology, GPO Box 1700, Canberra, ACT 2601, Australia

HAT transposable elements are members of a family of transposable elements that share a number of structural and functional characteristics. They are short, have conserved inverted terminal repeats, encode transposases containing common domains, and leave similar footprints at empty sites following excision from DNA. Members of the *hAT* element family isolated and characterized from plants have been found to be capable of accurate transposition in plant species distantly related to their original host species. Insect *hAT* elements are widespread and are also capable of accurate transposition in non-host species. The *hobo* element of *Drosophila melanogaster* can transpose when introduced into tephritids, muscids and calliphorids. Likewise, the *Hermes* element of *Musca domestica* can transpose in these and other families, including culicids and noctuids. Significantly, the *Hermes* element has been used to achieve genetic transformation of a non-host species, *D. melanogaster*, suggesting that this and other *hAT* elements may be harnessed as gene transfer vectors in a wide range of insect species. We will present data showing the structure and mobility properties of several insect *hAT* elements. In addition we will discuss how transposable element mobility assays can be employed to determine the mobility properties of members of the *mariner* element family.

THE PRESENCE OF RETROVIRUSES IN INSECTS AND THEIR POTENTIAL USE TO DEVELOP RETROVIRAL VECTORS FOR TRANSGENESIS

A. Bucheton, F. Chalvet, A. Kim, A. Pélisson, N. Prud'homme, C. Terzian and L. Teyssset

Centre de Génétique Moléculaire, CNRS, 91198 Gif-sur-Yvette, France

Retroviruses were considered to be restricted to vertebrates. However the genomes of many eukaryotes including insects contain transposable elements structurally related to proviruses of retroviruses, called LTR-retrotransposons. They contain LTRs (Long Terminal Repeats), but have only two ORFs corresponding to the genes *gag* and *pol*. They are not infectious because they are devoid of a third ORF coding for Envelope products that are responsible for the infective properties of retroviruses. Some insects contain elements like gypsy in *Drosophila melanogaster* that are much more similar to typical retroviruses than to LTR-retrotransposons. Gypsy contains three ORFs coding for putative polypeptides showing similarities to *gag*, *pol* and *env*.

We have shown that gypsy is an infectious retrovirus, the first retrovirus characterized so far in invertebrates. It can be transmitted from strains in which it transposes actively to strains devoid of functional elements, by egg plasm transplantation or by growing "empty" larvae in the presence of homogenized pupae of a stock containing transposing elements.

Multiplication of gypsy in the germline is under the control of a polymorphic locus that we called *flamenco* (*flam*) which maps at 20A1-3. This gene has a maternal effect on gypsy mobilisation: transposition occurs only in the progeny of females homozygous for permissive alleles of *flamenco*. We have shown that the transcripts of gypsy in *flam/flam* females accumulate in the somatic follicle cells of the ovaries. We think that particles are produced in these cells and that they infect the oocyte. Transposition observed in the next generation would correspond to integration of gypsy proviruses in flies derived from infected oocytes. We think that gypsy can be used to develop vectors in the same way as mammalian retroviral vectors. They might be used for transgenesis not only in *Drosophila melanogaster* but also in other insects.

INTEGRATION AND EXPRESSION OF PANTROPIC RETROVIRUSES INTO CELLS OF THE MALARIA VECTOR, *ANOPHELES GAMBIAE* (Giles) (DIPTERA: CULICIDAE)

A.A. James¹, T. Matsubara¹, R.W. Beeman², H. Shike³, N.J. Besansky⁴, O. Mukabayire⁴, S. Higgs⁵, J.C. Burns³

Dept. of Molecular Biology and Biochemistry, University of California, Irvine, California, USA - 1 Dept. of Pediatrics, Juntendo University, School of Medicine, Tokyo, Japan - 2 USGMRL, USDA, ARS, Manhattan, Kansas, USA - 3 Dept. of Pediatrics, Division of Immunology, University of California, La Jolla, CA, USA - 4 Division of Parasitic Diseases, Centers for Disease Control and Prevention, Chamblee, GA, USA - 5 Arthropod-Borne and Infectious Diseases Laboratory, Colorado State University, Fort Collins, CO, USA.

The lack of efficient techniques for stable genetic transformation of medically-important insects, such as anopheline mosquitoes, is an impediment to progress in developing novel disease control strategies. Currently available techniques for foreign gene expression in insects lack the benefit of stable inheritance conferred by integration. To overcome this problem, a new class of pantropic retroviral vectors has been developed in which the amphotropic envelope of the murine leukemia virus has been replaced by the G glycoprotein of vesicular stomatitis virus. The broadened host range of these viral particles allows successful entry, integration, and expression of heterologous genes in cultured cells of *Anopheles gambiae*, the principle mosquito vector responsible for the transmission of over 100 million cases of malaria each year. Mosquito cells in culture infected with a pantropic vector expressing hygromycin phosphotransferase from the *Drosophila melanogaster* hsp70 promoter were resistant to the antibiotic Hygromycin B. Integrated provirus was detected in infected mosquito cell clones grown in selective media. Mosquito-viral DNA junction fragments were isolated and sequenced providing evidence that the integration is viral-mediated. Thus, pantropic retroviral vectors hold promise as a transformation system for mosquitoes *in vivo*.

09-013

RETROTRANSPOSABLE ELEMENTS THAT SPECIFICALLY INSERT INTO THE 28S RIBOSOMAL RNA GENES: THEIR DISTRIBUTION IN INSECTS AND USE FOR GENETIC TRANSFORMATION

T. H. Eickbush, D. D. Luan, D. G. Eickbush and J. A. George
Department of Biology, University of Rochester, Rochester, NY 14627 USA

R1 and R2 are two different non-long-terminal repeat (non-LTR) retrotransposable elements which insert in the 28S ribosomal RNA genes. The insertion specificity of these elements has enabled rapid progress in studies of their distribution, evolution and retrotransposition mechanism. R1 and R2 have been found in all insect lineages and in all classes of Arthropods, where together they occupy from a few percent to over half of the total number of rDNA units. Their ability to be maintained within each lineage is predominantly a result of their vertical descent through the germline. The single ORF of the *Bombyx mori* R2 element encodes both an endonuclease specific for the 28S target site and a reverse transcriptase activity. The fundamental step in the R2 integration reaction is the cleavage of one strand of the 28S target site by this endonuclease, and the use of the 3' hydroxyl group exposed by the nick to prime reverse transcription of the R2 transcript. This mechanism, termed target-primed reverse transcription or TPRT, is therefore completely unlike the mechanism used by LTR-retrotransposable elements and retroviruses. Recently we have begun to utilize our understanding of the TPRT reaction to develop R2 into a transformation vector. When the R2 protein and RNA molecules containing the 250 nucleotide 3' untranslated region of a *B. mori* R2 element are injected into *Drosophila melanogaster* 1-2 hour embryos, integrated *B. mori* R2 elements are detected in the 28S genes of some adult survivors (somatic integrations) as well as in the offspring of these animals (germ-line transformation). Because entirely Lepidopteran components can be successfully used with a Dipteran, we are hopeful that this approach will work in many insects.

09-014

IKIRARA, A POTENTIALLY ACTIVE *ANOPHELES GAMBIAE* TRANSPOSON WITH SIMILARITIES TO *hAT* AND *Tc1*-LIKE ELEMENTS.

P. Romans, S.S. Leung, N.L. Quercia, D. Vasilaiuskas, R.K. Bhattacharyya, A.C. Colavita.

Department of Zoology and Program in Molecular Genetics and Molecular Biology, University of Toronto, Toronto, Canada

A novel DNA to DNA transposon *Ikirara* was found in the genome of the malaria vector mosquito, *Anopheles gambiae*. Related sequences were found in other members of the species complex, but not in *A. funestus* or *A. stephensi*. *Ikirara-1*, the first isolated family member, was found between two of the tandem vitellogenin (Vg) genes. Because this particular insertion was found only in one of nine tested *A. gambiae* s.s. strains, and because its 216 bp inverted terminal repeats are 100% identical, it is possible that transposition to the Vg locus was recent. The strain with the *Ikirara-1* insertion also appears to have greater variability in the genomic locations of its other *Ikirara* elements than strains lacking the insertion, but from the same geographic location and carrying the same chromosomal inversions.

DNA sequence derived from 5 different *Ikirara* elements showed similarities to two transposon superfamilies, *hAT* and *Tc1*-like elements found in a variety of animals and plants. The ends of the inverted repeats and the insertion site TA duplication are most similar to *Tc1*-like elements, while sequences internal to two of the elements, *Ikirara-29* and -25, show similarity to the conserved DNA-binding and carboxy termini of *hAT* transposases.

An excision assay based on *Ikirara-1* was developed to determine whether any genomic *Ikirara* elements are currently active. After passage of the excision tester plasmid through *A. gambiae* tissue culture cells, several putative excisions were recovered and sequenced. They showed complete transposon loss except for a short "signature" sequence.

SPECIES, POPULATION AND CHROMOSOME DISTRIBUTION OF A NOVEL FAMILY OF NON-LTR RETROTRANSPOSONS ISOLATED FROM THE SANDFLY *PHLEBOTOMUS PAPATASI* (DIPTERA: PSYCHODIDAE)

Jennifer Sackin, Paul Ready

Molecular Systematics Laboratory, Department of Entomology, The Natural History Museum, London U.K.

We have isolated members of a unique family (Rlppapa) of non-LTR retrotransposons (RTPs) which were found to have an atypically long 3' untranslated region (UTR) and an unusual repetitive "tail" sequence downstream of the polyadenylation signal. Examples of Rlppapa were isolated from *Phlebotomus (Phlebotomus) papatasi* by screening a genomic library with probes of homologous reverse transcriptase (RT) fragments cloned from PCR products. Contiguous Rlppapa restriction fragments from each genomic clone were sequenced from the RT gene downstream through the tail and into the DNA flanking each RTP. Using Southern and dot-blot hybridization analyses, Rlppapa sequences could be detected only in the genomic DNA of populations of *P. papatasi* and the related *Phlebotomus (Phlebotomus) duboscqi* but not of sympatric sandflies classified in other subgenera, suggesting vertical transmission of these RTPs. PCR was used to assess differences in chromosomal site occupancy (by employing reverse primers specific for each of the cloned flanking regions) and in the structure of different members of the Rlppapa family (by sequencing the variable 3' UTR). Phylogenetic analysis demonstrated the presence of 5 distinct subfamilies of Rlppapa, each of which was found in widely-separated geographical populations of *P. papatasi*. FISH, Southern hybridization and sequencing indicated a varied chromosomal distribution, with Rlppapa RTPs being detected in coding as well as non-coding regions. This observed variation suggested (recent) transpositional activity. This project is supported by a grant from the CEC/EU.

CHARACTERISATION OF A PUTATIVE FULL LENGTH MARINER ELEMENT IN THE MEDFLY *CERATITIS CAPITATA*.

L. Gomulski¹, C. Torti¹, P.A. Morandi¹, G. Damiani² A.R. Malacrida¹ and G. Gasperi^{1,3}

¹Department of Animal Biology, University of Pavia, Pavia, Italy.

²Institute for the Exploitation of Animal Germoplasm, CNR, Milan, Italy. ³Institute of Zoology, University of Sassari, Sassari, Sardinia, Italy.

The genome of the Mediterranean fruitfly, *C. capitata*, has previously been shown to contain several subfamilies of *mariner* elements (Robertson & MacLeod. Insect Molecular Biology 2: 125, 1993). However, in every case the elements were clearly non-functional due to multiple stop codons, deletions, insertions and frameshifts. Despite this discouraging background we were determined to identify a putative full length mariner element.

Mariner elements were amplified using primers complementary to the Inverted Terminal Repeat sequence of the deleted *mariner*-like element found in the *Adh1* intron of *C. capitata* (see accompanying poster of Gomulski et al.). A fragment of around 1300 bp was amplified from total genomic DNA. A number of clones were sequenced, the majority of which contained deletions and frameshifts. One clone, however, was found to possess an ORF of 339 amino acids with ~ 60% similarity to that of the *mos* element of *Drosophila mauritiana*.

The phylogenetic relationships between the *mariner* elements of *C. capitata* and other species were investigated. Those isolated in the present study are representatives of Robertson's mellifera subfamily.

GENE EXPRESSION IN THE INSECT FAT BODY

A.S. Raikhel, N. Dittmer, K.W. Deitsch, and M.Z. Kapitskaya
Department of Entomology, Michigan State University, East Lansing, MI USA

In insects, the fat body is the center of intermediate metabolism and is a powerful secretory organ producing hemolymph proteins. Elucidation of the molecular mechanisms underlying expression of fat body genes is of great importance to the effort toward utilization of molecular genetics in developing novel control strategies, particularly for vector insects. Expression of most fat body genes is controlled in a sex-, tissue-, and stage-specific manner. Transcription factors involved in these gene-regulatory pathways act synergistically to activate transcription of target genes. For the mosquito fat body, we have identified and cloned the cDNAs of transcription factors linked to the hormonal gene-regulatory pathway (ecdysteroid receptor and Ultraspiracle homolog) and the tissue-specific gene-regulatory pathway (hepatocyte nuclear factor 4 homolog, AaHNF4). Three isoforms of the AaHNF4 have been cloned and analyzed. Finding high expression of HNF4, a key transcription factor in the liver, in the mosquito fat body affirms the conservation of regulatory mechanisms for tissue-specific transcription. The regulatory regions of two fat body-specific mosquito genes are being analyzed: vitellogenic carboxypeptidase, a yolk protein precursor gene, expressed exclusively in the vitellogenic fat body, and lysosomal aspartic protease, expression of which is enhanced in this tissue. Regulatory regions of both these genes contain similar putative fat body enhancer elements which are homologous to the *Drosophila* yolk protein gene enhancer required for sex- and tissue-specific expression and contained Dsx and bZIP binding sites.

09-017

GENE EXPRESSION IN THE SALIVARY GLANDS OF THE MOSQUITO *Aedes Aegypti* (L) (DIPTERA: CULICIDAE)

A.A. James, N. Jasinskiene, A.C. Morris¹, G.B. Pott², K. Stark
Dept. of Molecular Biology and Biochemistry, University of California, Irvine, California, USA - 1 Inno Vision Communications, Aliso Viejo, CA, USA - 2 University of Colorado Health Sciences Center, Department of Cellular and Structural Biology, Denver, CO, USA.

The salivary glands of the vector mosquito, *Aedes aegypti*, express two classes of genes whose products are involved in feeding. One class of genes is expressed in both males and females, and the products appear to facilitate the ability of the mosquito to feed on sugars. The second class is expressed preferentially in females and its products are involved in hematophagy. The promoters of select salivary gland-specific genes have been evaluated for function in a number of assay systems including expression in mosquito cultured cells isolated salivary glands in culture, a transcription system *in vitro*, and by transposon-mediated transformation into the mosquito and the fruitfly *Drosophila melanogaster*. A putative promoter fragment from the *Maltase-like 1* gene functions in most of the systems tested while promoters of female-specific genes (*D7* and *Apyrase*) are more restricted in their ability to drive expression of reporter genes. Tissue-specific gene promoters can be used to target the expression of coding sequences that could interfere with parasite development and propagation.

IDENTIFICATION OF THE TARGET FOR SEX-PEPTIDE IN *DROSOPHILA MELANOGASTER*

T. Aigaki^{1,2}, S. Nakayama², K. Kaiser³
1 PRESTO, Research Development Corporation of Japan,
2 Department of Biology, Tokyo Metropolitan University, Hachioji-shi, Tokyo, Japan, 3 Department of Genetics, University of Glasgow, Scotland

Sex-peptide (SP), a male accessory gland peptide of *D. melanogaster*, is transferred to the female during copulation, and elicits reduction of receptivity and stimulation of ovulation/oviposition. Little is known about the primary target tissue(s) of SP in the females. We have attempted to identify the target(s) of SP with a novel strategy involving GAL4-UAS ectopic expression system. We constructed a membrane-bound form of SP, and expressed in a variety of tissues using randomly selected GAL4 enhancer trap lines. 33 out of 204 GAL4 lines showed both behavioral change and stimulated ovulation. The remaining 171 lines did not show any phenotypes, suggesting that there is only one target site for the two reaction pathways. Expression pattern analysis with tissue sections as well as Western blotting of head, thoracic, and abdominal extracts demonstrated that most of the positive lines express GAL4 in their heads. In the head, GAL4 was preferentially expressed in the antennal lobes, antennal nerves, and/or mushroom bodies, suggesting that SP could elicit behavioral changes and ovulation through interacting with the olfactory signal processing pathway.

09-020

THE ACETYLCHOLINESTERASE GENE OF *ANOPHELES ALBIMANUS*¹L. M.C. Hall, ¹C. A. Edwards and ²C.A. Malcolm¹Department of Medical Microbiology, London Hospital Medical College, University of London UK² School of Biological Sciences, Queen Mary and Westfield College, University of London UK

The acetylcholinesterase gene from insecticide susceptible *Anopheles albimanus* has been sequenced in full. The encoded protein sequence is very similar to that from *Anopheles stephensi*, with only 4% amino acid differences in the mature protein sequence (excluding the signal sequence and the excised C-terminal peptide). The DNA sequence encoding the mature protein differs at 20% of bases, but intron sequence have no significant homology between the species. The position of introns is conserved between the species, except that *An. albimanus* lacks the third intron of *An. stephensi*, which is also absent in *Drosophila melanogaster*. Intron lengths are very short.

The DNA sequence has also been determined from individual insects from an insecticide resistant population of *An. albimanus* (FEST). This was performed by direct sequencing of PCR amplified fragments. An almost complete sequence from one individual shows no nucleotide changes within coding sequences, and only three changes within intron sequences. This was further confirmed by determining the sequence encoding the lining of the active site in individual insects in which acetylcholinesterase assays from the heads had demonstrated homozygous resistance. The sequences known to be involved in resistance in *Drosophila melanogaster* and housefly were included in this region. Hence the mechanism of resistance in this population remains unclear.

09-021

CHARACTERISATION OF CHYMOTRYPSIN GENE STRUCTURE, EXPRESSION, AND ORGANISATION IN THE MALARIA MOSQUITO *ANOPHELES GAMBIAE*G.J. Lycett, H-M. Muller¹, A. Crisanti¹, J.M. CramptonLiverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK - ¹ Istituto di Parassitologia, Università degli Studi di Roma, La Sapienza, 00185 Roma 1, Italy.

The aim of this research is the characterisation of serine proteases in the malaria mosquito, *An. gambiae*. These enzymes are known to be agents of blood meal digestion and there is also evidence of their possible role in activating key enzymes in malaria parasite development in the mosquito host. We have identified and cloned a family of chymotrypsin genes from the KWA strain of *An. gambiae*. This family is clustered and contains 4 genes from hybridization studies. Two partially sequenced genes share 99% homology with the chymotrypsin genes (anchy1 and anchy2) previously isolated from the Suakoko strain of *An. gambiae*. We have completely sequenced a third gene (anchy3) that has 74% and 76% homology with the anchy1 and 2, respectively. Evidence from Southern blot hybridisation studies suggests that anchy3 is also present in the Suakoko strain, but has not yet been isolated from this source.

This analysis will eventually allow a direct comparison of the structure and function of the protein coding regions and possible regulatory regions of these very important protease genes.

09-022

MOSQUITO FERRITIN: TRANSCRIPTIONAL OR TRANSLATIONAL REGULATION?

D. Q.-D. Pham and J. H. Law

Department of Biochemistry and the Center for Insect Science, University of Arizona, Tucson, AZ 85721

In vertebrates, iron plays an essential role in many cellular processes, and perturbations of iron homeostasis often result in detrimental consequences. We started a study of iron metabolism in insects with the idea that knowledge obtained from this study could provide a means to control disease vectors. We initiated our study by examining ferritin (Fer), a well-known iron-storage protein in vertebrates. The expression of vertebrate *fer* is regulated mostly at the translational level. Previously, we have reported the isolation and sequence of a cDNA clone for a Fer subunit in the yellow fever mosquito *Aedes aegypti*. We now present the regulation of the *A. aegypti fer* and its homologue in the forest day mosquito *A. albopictus*.

In *A. albopictus* cultured cells, a moderate induction of Fer was seen at 4 hrs post-treatment with iron, and the accumulation of Fer continued until 24 hrs post-treatment. When *A. albopictus* cells or *A. aegypti* mosquitoes were exposed to actinomycin D prior to iron treatment, the level of *fer* mRNA was reduced significantly. This result suggested that transcriptional regulation plays an important role in the regulation of mosquito *fer*, unlike their mammalian counterparts. Treatment with cyclohexamide also attenuated the expression of *fer* mRNA, though not to the same degree as treatment with actinomycin D. Taken together, these data suggest that the expression of mosquito *fer* is regulated both at the transcriptional and translational level.

Funding for this work was provided by the John D. and Catherine T. MacArthur Foundation and the Department of Health & Human Services (DK09121 and GM29238).

09-023

EXPRESSION AND FATE OF HEXAMERIC SERUM PROTEINS IN THE MOSQUITO (DIPTERA: CULICIDAE)

H. Beneš, S.E. Korochkina, A. Gordadze, S.O. Zakharkin

Department of Biochemistry & Molecular Biology, University of Arkansas for Medical Sciences, Little Rock, Arkansas, USA

All insects studied to date express one or more types of hexameric serum proteins or hexamerins during preadult development. We are examining the arylphorin-like proteins of mosquitoes to determine the roles of these aromatic-rich hexamerins in adult development, cuticle deposition and immune system responses. Higher Diptera express two major, immunologically distinct arylphorin-like proteins, LSP1 and LSP2, during the last larval instar. In a previous characterization of hexamerin holoproteins from *Aedes aegypti* and *Anopheles gambiae* we showed that, in contrast, fourth-instar (L4) mosquito larvae express heterohexamers composed of both LSP1- and LSP2-like subunits. Using polyclonal antisera purified against the two major *Aedes* arylphorin-like subunits, Hex1 and Hex2, we have determined their appearance in L4 hemolymph and their utilization during the pupal and adult stages. In *A. aegypti*, Hex1 and Hex2 disappear completely from adult hemolymph by day 3 post-eclosion. The effect of nematode parasitism and the blood meal on larval and adult hexamerin expression in both anopheline and culicine mosquitoes is being examined. We have previously isolated cDNA clones encoding the *Aedes* Hex1 and Hex2 subunits, and more recently a cDNA for an arylphorin-like protein of *A. gambiae*. The *Anopheles* clone encodes an 83.5 kDa polypeptide, most closely related to the higher dipteran calliphorin and *Drosophila* LSP1 proteins; we note the absence of an insertion characteristic of these higher dipteran hexamerins at the junction of domains 1 and 2. We will report the sequence analysis and comparison of hexamerin cDNAs for both culicine and anopheline species. We are currently isolating genomic clones for both *Aedes* and *Anopheles* hexamerin genes with a view to identifying their tissue-specific promoters and enhancers.

09-024

GS3, A GENE ISOLATED IN THE COCKROACH *BLATTA ORIENTALIS*, MAY REPRESENT A COUNTERPART OF THE VERTEBRATE NEURO-HEMATOPOIETIC SUPERFAMILY

P. Cervella, C. Voena, M. DelPero, G. Stefanuto & E. Balleto

Dipartimento di Biologia Animale, Università di Torino, Torino - ITALY.

Despite the obvious morpho-physiological differences between insects and vertebrates, a number of regulatory and structural genes have been shown to play similar roles in both systems, providing the evidence that a common genetic program underlies the basic developmental decisions. Moreover, it has been suggested that a major factor in the evolution of eukaryotic gene families are gene duplications. As a consequence, paralogous genes could acquire new functions either by accumulating mutations and/or being recruited by different regulatory systems. A possible example of this tenet is the recently defined "neuro-hematopoietic factors" superfamily in vertebrates. A number of factors comprising neuro- (e.g. CNTF) and hematopoietins (e.g. IL6) have been ascribed to this superfamily, along with cytokines characterized by pleiotropy and functional redundancy (e.g. LIF/CDF).

By using a segment of the rat CNTF gene as a probe in Southern blotting experiments, we revealed the presence of positive signals in several insects. PCR amplifications using a number of mammalian-specific primers produced a segment from *B. orientalis* whose amino acid sequence shares similarities with the mammalian neuro-hematopoietic factors. Southern blot hybridization using this latter segment as a probe revealed that it represents a single-copy gene. Furthermore, Northern blotting analysis and RT/PCR experiments with cockroach-specific primers showed the existence of a transcript in all the body regions tested (head, thorax, abdomen). The full-length cDNA was obtained by using the RACE protocol. GS3 shares a degree of amino acid sequence similarity with the mammalian neuro-hematopoietic factors (10-14% amino acid identity and 36-38% conservative substitutions) comparable to that observed among different members of the vertebrate superfamily (e.g. 15% amino acid identity between human LIF/CDF and CNTF).

Further characterizations will require cloning of the GS3 gene in cockroach and other insects, and assessment of its pattern of developmental- or tissue-specific expression. However, it could be hypothesized the existence in insects of some trophic or differentiation factors related to the mammalian superfamily. If confirmed, new prospects to the interpretation of developmental mechanisms such as neurogenesis or hematopoiesis could be opened.

09-026

AN INTEGRATED GENOMIC MAP OF THE MALARIA MOSQUITO, *ANOPHELES GAMBIAE*, AND ITS USE IN IDENTIFYING *PLASMODIUM*-REFRACTORINESS GENES

L. Zheng, F. C. Kafatos

European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

We have developed a dense genetic map of *An. gambiae* (average resolution 1.6 cM), partly in collaboration with the laboratories of F.H. Collins and C. Louis. The map consists largely of microsatellite (simple sequence repeat) markers, which are conveniently scored by PCR using a small fraction of DNA from each mosquito. Additionally, it incorporates RAPD, morphological and biochemical markers. A significant number of markers have been mapped by *in situ* hybridization to polytene chromosomes, thus correlating the map with cytogenetic locations. The map has been used in a collaboration with F.H. Collins, to identify and localize two genetic loci that are involved in refractoriness of *An. gambiae* to *Plasmodium*, based on encapsulation of oocytes. The map has also been used, in collaboration with K. Vernick, to identify and map preliminarily a third locus, which is involved in the refractoriness of *An. gambiae* to *P. gallinaceum*, based on lysis of ookinates in transit through the midgut epithelium. Prospects for molecular cloning of these genes and other phenotypically interesting loci will be discussed.

09-025

INSECT GENOMICS: PERSPECTIVES FROM *DROSOPHILA*

C. Louis

Dept. of Biology, University of Crete and Institute of Molecular Biology and Biotechnology, FORTH, 711 10 Heraklion, Crete, Greece

Since the beginnings of this century *Drosophila melanogaster* has been the workhorse of genetics. The wealth of knowledge accumulated is unequalled by information on any other higher animal, and the development of molecular tools through the research on the fruitfly has promoted the knowledge on the development and genetics of other organisms from bacteria to man. It is now a well established fact that without the availability of genomic maps (initiated by Morgan on the genetic and Bridges on the cytogenetic level), this progress would have been unthinkable. The last few years has seen, through the advent of molecular techniques, an increased effort to establish for *Drosophila* also an integrated physical map that can be linked to the existing ones. The development of one such map by the European *Drosophila* Mapping Project (based on cosmid contig mapping and STS analysis) will be presented and the possible utilisation of the data for the study of other insects will be discussed.

09-027

A BACTERIAL ARTIFICIAL CHROMOSOME LIBRARY FOR THE MALARIA VECTOR *ANOPHELES GAMBIAE*

Frank H. Collins, Division of Parasitic Diseases, Centers for Disease Control and Prevention, Atlanta, GA, 30333, USA

A Bacterial Artificial Chromosome (BAC) genomic library for the malaria vector *Anopheles gambiae* has been constructed. This library contains 12,288 clones, representing approximately four genomic equivalents. Inserts in 100 randomly selected clones ranged from 70 kb to 145 kb, with an average insert size of 110 kb. Five clones with inserts larger than 110 kb were stable when grown for more than 100 generations in liquid media. No chimeric clones were detected among 40 BAC clones mapped by *in situ* hybridization to the *A. gambiae* polytene chromosomes. This library will be particularly useful for positional cloning applications.

09-028

SSCP ANALYSIS FOR RAPID LINKAGE MAPPING

M.F. Antolin

Department of Biology, Colorado State University, Ft. Collins, CO USA

Analysis of genomes via Random Amplified Polymorphic DNA (RAPD-PCR) allows efficient construction of saturated linkage maps. When analyzed by agarose gel electrophoresis, most RAPD markers segregate as dominant alleles, reducing the amount of linkage information obtained. We have developed a mapping method based upon the use of Single Strand Conformation Polymorphism (SSCP) analysis of RAPD markers via polyacrylamide gel electrophoresis (RAPD-SSCP). We have used RAPD-SSCP to generate linkage maps in a haplodiploid parasitic wasp (*Bracon (Habrobracon) hebetor*) and two species of diploid mosquitos (*Aedes*). RAPD-SSCP analysis reveals segregation of codominant alleles at markers that appeared to segregate as dominant (band presence/band absence) markers or appeared invariant on agarose gels. Our SSCP protocol uses silver staining of large thin polyacrylamide gels and reveals more polymorphisms than agarose gel electrophoresis. The use of this method allows creation of saturated linkage maps in 6-10 weeks that are comparable to linkage maps created by alternative means (e.g. RFLP and visible mutations). Forty five percent of markers segregated as codominant loci in *B. hebetor*, while 11% segregated as codominant loci in *Aedes*. SSCP analysis of RAPD-PCR markers offers a rapid and inexpensive means of constructing intensive linkage maps of many species.

09-029

CONSTRUCTING A MOLECULAR LINKAGE MAP FOR THE DOMESTICATED SILKWORM, *BOMBYX MORI*M. R. Goldsmith, J. Shi, D. G. Heckel¹, D. R. Mills, N. Lawson, S. W. Marino, J. Leri, M. A. Choquette.

Department of Biological Sciences, University of Rhode Island, Kingston, RI USA - 1 Department of Biological Sciences, Clemson University, Clemson, SC USA

We are constructing a linkage map for the silkworm based on restriction fragment length polymorphisms (RFLPs) using as probes anonymous cDNAs derived from an early follicular library, low copy number (10-15) repeats, and cloned sequences of known genes. A number of these markers serve as reference points to the conventional linkage maps. The initial RFLP map of 413 cM was constructed with a single F2 cross, and covers 15 linkage groups and 8 unlinked loci representing 23 of the 28 chromosomes. We are looking for additional linkage groups by means of backcrosses using heterozygous females, which have no crossing over, and homozygous males, followed by confirmation of linkage relationships and establishment of map position using additional F2 crosses. This scheme uncovered significant polymorphism in a genetically improved strain, C108, despite more than 20 generations of inbreeding in the laboratory.

Pilot studies are also underway to investigate the feasibility of mapping quantitative trait loci (QTLs) in this species, such as duration of the last larval instar, time to emergence, and pupal and cocoon weights. A known sex-linked gene, *Lm* (late maturity; 1-2.0), which has a major affect on these characters, is serving as an internal control.

09-030

LINKAGE MAPPING IN LEPIDOPTERA: TECHNICAL CHALLENGES, PRACTICAL APPLICATIONS, AND COMPARATIVE GENOMICS

D.G. Heckel, L.C. Gahan, M.R. Goldsmith¹, L.E.L. Raijmann², B.E. Tabashnik³, and S.C. Trowell⁴

Department of Biological Sciences, Clemson University, Clemson, SC, USA - 1 Department of Biological Sciences, University of Rhode Island, Kingston, RI, USA - 2 Institute for Systematics & Population Biology, University of Amsterdam, Amsterdam, The Netherlands - 3 Department of Entomology, University of Hawaii, Honolulu, HI, USA - 4 Division of Entomology, CSIRO, Canberra, ACT, Australia

Construction of linkage maps in Lepidoptera is complicated by the large number of small chromosomes and the lack of general computational techniques to account for achiasmatic oogenesis in females. But progress has been greatly facilitated by development of molecular markers based on DNA polymorphisms, and the extension of the lod score method to deal with the unique genetic system of Lepidoptera. We describe the current status of the linkage map of the tobacco budworm *Heliothis virescens* (F), a polyphagous noctuid crop pest, and its application to localizing genes conferring resistance to chemical insecticides and endotoxins from *Bacillus thuringiensis* (Bt). Recently-developed computational methods and molecular techniques have also aided linkage mapping in *Bombyx mori*, *Yponomeuta padellus*, *Plutella xylostella*, and *Helicoverpa armigera*. The prospects for comparing the linkage maps of these Lepidoptera are discussed, and a system of universal anchor loci is proposed for this purpose. Comparative linkage mapping will not only shed new light on genomic evolution in the Lepidoptera, it will facilitate identification of homologous loci conferring resistance to Bt, an urgent concern in the pests *H. virescens*, *P. xylostella*, and *H. armigera*. It will also enhance the utility of the well-studied *B. mori* as a model for physiological and developmental processes in other Lepidoptera.

09-031

GENOME ANALYSIS AND MAPPING OF BEHAVIORAL TRAIT LOCI IN THE HONEY BEE

G. J. Hunt, E. Guzmán-Novoa¹, R. E. Page, Jr.²

Department of Entomology, Purdue University, West Lafayette IN USA - 1 SARH, Mexico City, Edo. de Mexico, Mexico - 2 Department of Entomology, University of California, Davis, CA USA

Detailed linkage maps of the honey bee, *Apis mellifera* L., have been constructed by analyzing the segregation of RAPD markers (random amplified polymorphic DNA) in haploid males. Although the honey bee has a genome that is similar to *Drosophila* in the amount of repetitive and total DNA, the size of the linkage map indicates a very high rate of meiotic recombination. The crossover rate in the honey bee is higher than that reported for other higher eukaryotes and will enable map-based cloning of genes.

The maps have been used to identify loci with effects on behavioral traits. Two loci that influenced the resource choice of foragers (pollen versus nectar) were mapped. Loci that contributed to the propensity to sting in crosses with bees of African descent (*A. m. scutellata*) were also identified. The genetic analyses were performed on haploid male honey bees and the inheritance of RAPD marker alleles was then correlated with the behavior of the female progeny in colonies that these males fathered. Sequence-tagged sites (STS) have been developed that are linked to genes that affect pollen-foraging and stinging behaviors. These STS markers will be useful for mapping and studying gene effects in other populations of bees.

09-032

BIOSYNTHESIS, DISTRIBUTION, AND MODE OF ACTION OF PBAN IN *HELICOVERPA ZEA* (LEPIDOPTERA: NOCTUIDAE).

W. Roelofs¹, R. Jurenka², W.K. Ma¹

1 Department of Entomology, Cornell University, Geneva, NY USA - 2 Department of Entomology, Iowa State University, Ames, IA USA

Pheromone production in most moths is regulated by pheromone biosynthesis activating neuropeptides (PBAN). Biosynthesis and processing of the PBAN gene occurs in three sets of cells in the subesophageal ganglion (SEG). PBAN and 4 other neuropeptides from the same gene are expressed in the SEG and distributed to the corpora cardiaca in adult females. PBAN interacts directly with receptors on the pheromone gland. We will review the current concepts related to how PBAN stimulates the pheromone biosynthetic pathway at the level of the pheromone gland cell. Evidence will be presented for the role of calcium and cAMP in the signal transduction process. Current concepts on the signal transduction pathways involved in PBAN mode of action will be discussed.

09-034

NOVEL NEUROPEPTIDES FROM THE DESERT LOCUST, *SCHISTOCERCA GREGARIA*.

A. De Loof¹, D. Veelaert¹, L. Schoofs¹, J. Vanden Broeck¹, S. Tobe², P. Passier³, B. Devreese⁴, F. Couillaud⁵.

1 Zoological Institute, Katholieke Universiteit Leuven, Belgium - 2 Department of Zoology, University of Toronto, Canada - 3. Department of Experimental Zoology, University of Utrecht, The Netherlands -4- Department of Biochemistry, University of Gent, Belgium -5- Département de Physiologie des Invertébrés, Bordeaux, France

By immunocytochemical staining we first demonstrated the presence of allatostatin-like material in the corpora allata of the locust. Next, immunopositive material was chromatographically purified from an extract of 7000 brains of *Schistocerca*. This yielded 9 peptides, which were named "schistostatins". They belong to the allatostatin A family, first isolated from the cockroach *Diploptera punctata*. One of these peptides, schistostatin-2¹¹⁻¹⁸, is the only purified peptide of this family that has no effect on juvenile hormone biosynthesis in the cockroach. The endogenous juvenile hormone production by isolated corpora allata of *Schistocerca* is very low. Perhaps, this is a reason why we were not able to demonstrate a clear inhibiting effect of the schistostatins in this assay system. *Locusta*-myoinhibiting peptide on the other hand was active at high concentrations. Schistostatins and *Locusta*-myoinhibiting peptide are potent inhibitors of spontaneous contractions of locust oviducts. Schistostatins are present in the hemolymph and their titer changes during certain developmental stages. Upon injection into adults, the schistostatins induce the appearance of an as yet only partially characterised 88 kDa protein in the hemolymph. The schistostatin preprohormone was cloned. It encodes ten putative peptides of which 8 were purified by HPLC. We also purified a peptide which seems to be a potent releasing factor of adipokinetic hormone from the corpus cardiacum of both *Locusta migratoria* and *Schistocerca gregaria*.

09-033

MOLECULAR BIOLOGICAL AND SIGNAL TRANSDUCING ASPECTS OF INSECT ADIPOKINETIC HORMONES

J. Bogerd¹, D.O. Ogoyi², W.J.A. Van Marrewijk¹, and D.J. Van der Horst¹

¹Biochemical Physiology Research Group, Department of Experimental Zoology, Utrecht University, The Netherlands

²Department of Biochemistry, University of Nairobi, Kenya

Neurosecretory cells in the corpora cardiaca (CC) of the migratory locust, *Locusta migratoria*, synthesize three adipokinetic hormones (AKHs) I, II and III. In the adult locust, AKHs I and II are released into the hemolymph during flight and stimulate the release of carbohydrate (via activation of glycogen phosphorylase [GPh]) and lipid (probably via activation of triacylglycerol lipase) from the fat body. The released substrates serve for energy generation in the flight muscles. Data on release of AKH III during flight are lacking so far; however, injected AKH III reveals actions similar to those of AKHs I and II.

To date, information on the mRNA and/or gene structure of AKHs I and II is restricted to *Schistocerca* and *Manduca* species, whereas information on mRNA and/or gene structure of AKH III (which has been only identified in *Locusta* so far) is not available at all. For the migratory locust, we report the cDNA sequences encoding the three different AKH precursors. The AKH I and II precursors of *L. migratoria* are highly homologous to their *S. gregaria* and *S. nitans* counterparts, whereas the AKH III precursor of *L. migratoria* is more homologous to the *M. sexta* AKH precursor. *In situ* hybridization studies are presented, revealing the sites of expression of the three different AKH genes. In addition, we show that flight activity increases the three different AKH mRNA steady-state levels.

Since most neuropeptide receptors are members of the family of G protein-coupled receptors, we argued that AKH receptors may also be coupled to G proteins. To investigate this, the G_s activator cholera toxin (CTX) and the G_i inhibitor pertussis toxin (PTX) were applied to isolated fat bodies. Whereas CTX enhances both cAMP levels and GPh activity *in vitro*, PTX has no effect. Increases induced by CTX and one of the AKHs are not additive, suggesting them to share the same signalling pathway, namely via a G_s protein. Moreover, the G protein inhibitor GDPβS strongly attenuates GPh activation by the three AKHs, indicating that the receptor(s) for the AKH(s) are coupled to G_s.

In order to isolate and characterize the AKH receptor(s), we recently started with an expression cloning strategy using a colorimetric assay for measuring activation of G_s- and G_q- coupled signalling pathways.

09-035

SYNTHESIS AND EXPRESSION OF A GENE ENCODING A PUTATIVE INSECT NEUROPEPTIDE PRECURSOR IN TOBACCO

R. Rao, F. Pennacchio¹, E. Filippone, C. Malva², L.M. Monti, E. Tremblay³

Dipartimento di Scienze Agronomiche e Genetica Vegetale, Università di Napoli Federico II Italy; 1 Dipartimento di Biologia, Difesa e Biotecnologie Agro-Forestali, Università della Basilicata, Potenza, Italy; 2 Istituto Internazionale di Genetica e Biofisica C.N.R., Napoli, Italy; 3 Dipartimento di Entomologia e Zoologia Agraria, Università di Napoli Federico II Italy

The use of insect neuropeptides as an innovative approach for more effective strategy of integrated pest management is a very attractive perspective as neuropeptides are able to interfere with several insect physiological processes. In order to assess the feasibility of such approach a model peptide, proctolin, was selected for a preliminary set of experiments. Proctolin oral activity and gut absorption rate were evaluated in *Helicoverpa armigera* last instar larvae: the peptide proved to be orally active with an absorption rate of about 0.1-0.5%. A synthetic gene encoding for a putative proctolin precursor containing multiple copies of the neuropeptide in tandem array was assembled and subcloned in a plant expression vector later mobilized in *Agrobacterium tumefaciens* and used to transform tobacco plants. Phenotypically normal transformants with single or multiple insertions, were genetically stable over several generations and showed different level of expression of the synthetic gene.

09-036

EXPRESSION OF TRYPSIN MODULATING OOSTATIC FACTOR ON THE COAT PROTEIN OF TOBACCO MOSAIC VIRUS: A NEW BIORATIONAL INSECTICIDE AGAINST MOSQUITO LARVAE

D. Borovsky, S. Shivprasad¹, D.J. Lewandowski¹, C.R. Powell², W.O. Dawson¹, H.L. DeBondt³, A. DeLoof⁴.

University of Florida, FMEL, Vero Beach, FL USA -

1 University of Florida, Lake Alfred, FL USA - 2 University of Florida, Fort Pierce, FL USA - 3 Catholic University, Department of Pharmacology, Leuven, Belgium - 4 Catholic University, Zoological Institute, Leuven, Belgium

Trypsin modulating oostatic factor (TMOF), a decapeptide that modulates trypsin biosynthesis in the midgut of female mosquito was cloned into the carboxyl terminal sequence of the coat protein of Tobacco Mosaic Virus (TMV) with a trypsin cleavage site. Feeding TMOF to adult mosquito mixed with the blood meal stopped trypsin biosynthesis and egg development. Feeding mosquito larvae with TMOF or TMV-TMOF complex stopped larval growth and caused larval death. The mechanism and the mode of action of TMOF and its analogs on trypsin biosynthesis, cloning and expression and 3 dimensional molecular modeling of the TMV-TMOF complex will be discussed.

09-037

CLONING OF THE LOCUST (*SCHISTOCERCA GREGARIA*) ALLATOSTATIN PRECURSOR cDNA

J. Vanden Broeck¹, D. Veelaert¹, L. Schoofs¹, W. Bendena², S. Tobe², A. De Loof¹.

¹Laboratory of Developmental Physiology and Molecular Biology, Zoological Institute, K.U.Leuven, Belgium;

²Department of Zoology, University of Toronto, Canada.

In insects, juvenile hormone biosynthesis (in the corpora allata) seems to be regulated by peptides originating from the nervous system. Members of the allatostatin A peptide family (the -FGLa AST-family) were first identified in cockroach species and have now been isolated from a number of distinct insect orders. Recently, we purified and sequenced nine AST-immunopositive peptides from the desert locust *Schistocerca gregaria* and called them schistostatins. One of these, schistostatin-2¹¹⁻¹⁸, is a truncated product of schistostatin-2.

Based on the peptide structures, we cloned the prepro-schistostatin cDNA. This sequence encodes a polypeptide which contains ten distinct AST variants. All purified schistostatins are found in this single precursor. Its organization displays some remarkable differences when compared to the ones known from cockroach species. Expression of the schistostatin gene in different locust tissues was monitored by northern analysis.

09-038

MULTIPLE SUBFAMILIES OF MARINER-LIKE TRANSPOSABLE ELEMENTS IN THE TEPHRITID FRUIT FLY *BACTROCERA TRYONI*

C.L. Turney¹, C.J. Coates², P.W. Atkinson², J. Sved¹ and M. Frommer¹
¹ School of Biological Sciences, University of Sydney, NSW, Australia;
² Commonwealth Scientific and Industrial Research Organisation, Division of Entomology, Canberra, ACT, Australia.

DNA sequences related to the transposable element *mariner* have been found to be abundant in the genome of the Queensland fruit fly, *Bactrocera tryoni*, a tephritid species endemic to Australia where it is a serious pest of commercial fruit production. Multiple PCR fragments were cloned following their amplification from genomic DNA by use of degenerate oligonucleotide primers designed to amino acid sequences conserved between *mariner*-like transposases. DNA sequence variants from the cloned *B. tryoni* fragments can be grouped into at least two subfamilies of *mariner*-like transposase genes.

Representatives of each sequence class were used as probes in the screening of a *B. tryoni* genomic DNA library in lambda phage, resulting in a very large number of hybridizing clones. *B. tryoni* elements characterized from several independent positive clones were 90-95% similar to each other with partially conserved inverted terminal repeats (ITRs) of 30bp. These elements shared an overall DNA sequence identity of about 65% with previously characterized members of the 'mellifera' subfamily. All characterized *B. tryoni* elements appear non-functional, with transposase gene regions containing deletions and/or frameshift mutations.

To investigate whether the *B. tryoni* genome could currently support the transposition of *mariner*-like elements, plasmid-based transient assays were used. Microinjected constructs containing the related *Drosophila mauritiana mariner Mos1* ITRs underwent excision and transposition at a low frequency within *B. tryoni* embryos when an exogenous source of *Mos1* transposase was co-injected.

09-040

DISTRIBUTION OF *T1* AND *PEGASUS* TRANSPOSABLE ELEMENTS IN A NATURAL POPULATION OF *AN.GAMBIAE*.

Odette Mukabayire & Nora J. Besansky
 Division of Parasitic Diseases, Centers for Disease Control and Prevention, Atlanta, GA 30333, USA

An.gambiae is becoming a target for genetic studies because of its importance as principal vector of human malaria in sub-Saharan Africa. Investigations of transposable elements are an important component of these studies because of their potential as vehicles for germline transformation and population genetic markers. Previously we have reported the chromosomal locations and stability of four transposable elements (*T1*, *Q*, *mariner* and *Pegasus*) in a laboratory strain of *An.gambiae*. There is no direct evidence that any of these elements are currently mobile, but *Pegasus* showed relatively high levels of polymorphism. To assess the degree of polymorphism in wild mosquito populations, we extended our study to a population of *An.gambiae* sampled from western Kenya. Using *T1* and *Pegasus* probes, we found that both transposable elements are polymorphic for all five chromosomal arms (except for *Pegasus* which has only one fixed site on X-arm), with average site occupancies of 0.44 and 0.26, respectively. In addition, the total number of copies differed between individuals, ranging from 29 to 43 for *Pegasus*, and 65 to 108 for *T1*. The reasons for this remarkable degree of polymorphism are being investigated.

09-039

MINOS TRANSPOSASE INDUCED INTERPLASMID TRANSPOSITION IN *D. Melanogaster* S2 CELLS

A. Klinakis, T. Loukeris, C. Savakis¹
 Institute of Molecular Biology and Biotechnology, Foundation for Research and Technology Hellas, Heraklion, Crete, Greece
¹ Division of Medical Sciences, Medical School, University of Crete, Heraklion, Crete, Greece

Minos, a *Tc1*-like element from *Drosophila hydei*, encodes a transposase in two exons split by a 60 bp intron. This small intron is correctly spliced in *Drosophila melanogaster* carrying a single copy of a modified *Minos* element in which the transposase gene has been placed under heat-shock promoter control (Franz *et al.* 1994). The spliced message encodes for a protein that has been shown to have the properties of a transposase:

1) It can catalyze precise insertion of *Minos* transposons in the *D. melanogaster* (Loukeris *et al.* 1995a) and in the *Ceratitis capitata* genome (Loukeris *et al.* 1995b) in flies co-injected with helper and transposon plasmids at the preblastoderm stage.

2) It induces excision and transposition of these insertions in *D. melanogaster* transformants both in somatic and germ line cells (Loukeris *et al.* 1995a; Arca *et al.* submitted).

A system that would permit quick and efficient evaluation of new and modified tools for transformation, such as transposon and sources of transposase, would be of great help in designing such tools. Based on previous observation that *P* elements can excise, in the presence of transposase, not only from resident sites in the genome, but also from plasmids introduced into embryos or cell lines (Rio *et al.* 1986, O' Brochta and Handler, 1988; Rio *et al.* 1988), we have established a "transient excision" assay for *Minos* using *D. melanogaster* Schneider (S2) cells. We have also established a "transient interplasmid transposition assay" for *Minos* using the sucrose gene as a target (O' Brochta *et al.* 1994).

The transposition assay is based on the co-transfection of 3 plasmids: a "helper plasmid" coding for the transposase, a "donor" plasmid carrying a genetically marked, non-autonomous transposon, and a third plasmid carrying the sucrose gene. Transpositions of the marked transposon into the sucrose gene are selected for growth in the presence of sucrose and the appropriate antibiotics. Several events have been isolated and characterized at the molecular level.

The assay is used to study a) the properties of engineered transposases in vivo, b) the cis-acting DNA sequence requirements for *Minos* transposition, and c) transposition of *Minos* in different species.

09-041

ISOLATION AND ANALYSIS OF MARINER ELEMENTS IN THE TEPHRITID FLIES, *CERATITIS CAPITATA*, *C. ROSA* AND *TRIRHITHRUM COFFEA*

C. Torti¹, P. Capy², L. Gomulski¹, A.R. Malacrida¹ & G. Gasperi^{1,3}

¹Department of Animal Biology, University of Pavia, Pavia, Italy.

²Laboratoire de Populations, Génétique et Evolution. CNRS, Gif/Yvette, France. ³Institute of Zoology, University of Sassari, Sassari, Sardinia, Italy.

Mariner transposable elements were isolated from three Tephritid species, *Ceratitis capitata*, *C. rosa* and *Trirhithrum coffea*. These species are sympatric in parts of their ranges, in particular, in Kenya where they are a pest of coffee.

The *mariner* elements were amplified by PCR using Inverted Terminal Repeat sequences (see accompanying posters of Gomulski *et al.*) and internal conserved regions as primers. Using the ITR primer, PCR products of around 1.3 Kb, were amplified in each species. These were cloned and sequenced. A high degree of similarity was found between the elements from each species. Southern blot analysis of genomic DNA indicates high copy numbers in these species.

We investigate the phylogenetic relationships of these elements with those from other species. The phylogeny of the elements is compared with the phylogeny of the species.

09-042

ANOPHELES GAMBIAE : EVIDENCE OF TYPE II TRANSPOSONS

J.M. Kirk, A.M. Warren and J.M. Crampton

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK.

We are interested in characterising Type II transposable genetic elements (TGEs) in *An. gambiae*. We have employed the polymerase chain reaction (PCR) to amplify sequences homologous to *Tc1*-like TGEs based on degenerate primers. Using these primers with an *An. gambiae* DNA template a 384 base pair sequence has been generated and cloned (designated TRANG1). Cloned TRANG1 demonstrates significant sequence homology to the transposase gene of *Tc1*-like elements. The existence of sequences homologous to TRANG1 in closely related mosquito strains, variation in copy number and location have been suggested by the probing of genomic Southern blots. Screening of a representative *An. gambiae* genomic library with cloned TRANG1 fragment has identified 4 genomic clones. After Southern blotting, the fragments showing homology to TRANG1 have been subcloned into plasmid vectors and are being sequenced. In order to widen the search for divergent *Tc1*-like elements the entire genomic PCR product generated by the degenerate primers has been used to identify 15 additional genomic clones.

09-043

THE HERMES TRANSPOSABLE GENETIC ELEMENT AS A POTENTIAL MOSQUITO TRANSFORMATION VECTOR

A. King, P. Eggleston and J.M. Crampton

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK

The lack of a reliable method to transfer genes into insects of medical importance still represents a major stumbling block in the development of transgenic technology. Until such procedures are routine, progress in the molecular genetic analysis of these insect systems and the exploitation of transgenic technology will be slow. In order to assess their potential as the core of a mosquito transformation system we are currently testing the integration efficiency of the housefly (*Musca domestica*) *hermes* transposable genetic element in the genome of *Aedes aegypti*. Two approaches are being undertaken. Firstly, to detect *hermes* integration, a two element vector/helper system, comprising of the *hermes* open reading frame controlled by the *Drosophila hsp70* heat-shock promoter and a marked *hermes* element, containing the *opd* gene controlled by the same promoter, are co-microinjected into early *Ae. aegypti* embryos. Potential G1 transformed offspring are selected using the nerve agent paraoxon. Southern blotting and sequencing are used to determine the nature of any integration events. Secondly, to detect transposition of *hermes* in the mosquito cytoplasm, a similar vector/helper system, containing the bacterial marker kanamycin, are coinjected with the target sucrose gene. In order to detect possible transposition events, rescued plasmid from 24 hour old heat-shocked embryos are transformed into *E. coli*, kanamycin resistant sucrose sensitive colonies are selected. Southern blotting and sequencing of rescued plasmid DNA are being used to determine transposition events. The results from these experiments will be described and discussed in relation to whether *hermes* has potential as the core of a mosquito transformation vector system.

09-044

ZEBEDEE1: A NOVEL COPIA-TY1 TRANSPOSABLE ELEMENT IN THE GENOME OF THE MEDICALLY IMPORTANT MOSQUITO, Aedes Aegypti

A.M. Warren, M.A. Hughes, J.M. Crampton

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK

We have utilised PCR to directly identify a novel *cop*ia-Ty1 retrotransposon element, *zebedee1*, in the genome of the mosquito *Aedes aegypti*. *Zebedee1* is 3505 bp long and may be flanked by 21 bp direct terminal repeat sequences. A single open reading frame (ORF) of 972 amino acids has the coding potential for a polyprotein with homology corresponding to the conserved amino acid motifs of Long Terminal Repeat (LTR)-retrotransposon protease, integrase and reverse transcriptase. There appear to be less than 10 copies of *zebedee1* in the genomes of different strains of *Ae. aegypti*, and transcripts of the element have been detected in cultured mosquito cells by RT-PCR. Despite the lack of LTRs or a *gag* homologue, phylogenetic analyses place *zebedee1* within the *cop*ia-Ty1 group of LTR retrotransposons, showing significant homology to *cop*ia from *D. melanogaster*. Interestingly, in one case we have identified a new mosquito LINE (Long Interspersed Nucleotide Element), *JAM1*, integrated in close proximity to *zebedee1* (see Hughes *et al.*, accompanying poster). This element is downstream of *zebedee1* and has an opposite polarity.

09-045

JAM1: A NOVEL LINE TRANSPOSABLE ELEMENT IN THE GENOME OF THE MEDICALLY IMPORTANT MOSQUITO, Aedes Aegypti

M.A. Hughes, A.M. Warren, J.M. Crampton

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK

We have utilised PCR to directly identify a novel *cop*ia-Ty1 retrotransposon element, *zebedee1*, in the genome of the mosquito *Aedes aegypti* (see accompanying poster by Warren *et al.*). Interestingly, during this search we have identified a new mosquito LINE (Long Interspersed Nucleotide Element), *JAM1*, integrated in close proximity to *zebedee1*. This element is downstream of *zebedee1* and has an opposite polarity. *JAM1* is flanked by imperfect 20 bp repeats and is 3364 bp long with two ORFs; ORF1 codes for a polypeptide of 176 amino acids long and contains a copy of the nucleic acid binding motif; ORF2 codes for a polypeptide 835 amino acids long and has homology to LINE-like reverse transcriptases. Many copies (~1,000) of *JAM1* are present in different strains of *Ae. aegypti*, and an abundant transcript of ~7 kb homologous to the element has been detected in cultured mosquito cells. Neither long, 3' poly A stretches or host direct flanking sequences at the site of integration in *zebedee1* are observed.

09-046

TRANSPOSABLE ELEMENTS COULD BECOME TARGETS ONE ANOTHER FOR INSERTION

Y. Nakajima¹, W. Akutsu, K. Hashido, K. Funatsuki, K. Tsuchida and H. Maekawa, Division of Radiological Protection and Biology, National Institute of Health, Tokyo, Japan - 1 present address: Laboratory of Gene Technology, University of Ryukyus, Okinawa, Japan

Six to nine fragments from 0.6 to 4.2kb, were amplified in genomic DNA of *Bombyx mori* by PCR using inverted repeat of transposon, mariner, from *Hyalophora cecropia* as a primer. Almost all bands were observed in eight tested strains of *B. mori*. The longest fragment of 4.2kb was cloned from PCR products of the N4 strain as a plasmid, pBmTNER1, and sequenced. This clone contained mariner (1.2kb), a known *B. mori* retroposon, Bm2 (0.2kb), and a retrotransposon, BMC1 (2.8kb). The sequence data revealed that Bm2 had been integrated into mariner, and then BMC1 had been integrated into Bm2 with a target sequence duplication at each flanking region. The isolated mariner whose copy number is less than 50, was a defective type containing no ORFs except for the inserted region of Bm2 and BMC1. As the consensus sequences conserved in wide spread mariner families were unable to amplify any fragments in *B. mori* by PCR, there may not be any active mariners. These data suggest that transposable elements could be available to one another as targets for insertion in *B. mori*.

09-048

INCREASED SURVIVORSHIP AND EXPRESSION OF FOREIGN RNA AMONG MICROINJECTED PINK BOLLWORM EMBRYOS (LEPIDOPTERA: GELECHIIDAE).

S. T. Thibault, J. J. Peloquin, T. A. Miller
Department of Entomology, University of California, Riverside, CA USA.

mRNA transcribed *in vitro* was introduced into *Pectinophora gossypiella* embryos by microinjection. We have optimized methods to increase survivorship and demonstrated translation of injected RNA into functional protein. Here, we report a five-fold increase in survivorship with the electromechanical Eppendorf 5171 system over a manually operated Narashige unit and the use of β -galactosidase as a positive control for translation.

09-047

THE GENOMES OF MOST INSECTS AND OTHER ANIMALS HAVE MULTIPLE MEMBERS OF THE *Tc1* FAMILY OF TRANSPOSABLE ELEMENTS

R. M. P. Avancini¹, K. K. O. Walden, H. M. Robertson
Department of Entomology, University of Illinois, Urbana, IL USA
- 1 Departamento de Parasitologia, Universidade Estadual de Campinas, Campinas (SP), Brazil

A PCR assay was employed to detect sequences homologous to the transposase gene of the *Tc1* family of transposable elements in a wide variety of insects and other animals. Amplification products of the appropriate size were obtained from most insects (92 of 108 examined; 85%), most other invertebrates (33 of 43; 77%), and many vertebrates (18 of 36; 50%). Sequencing of a sample of cloned PCR products from eight insects, one hydra, and two frogs revealed that each had multiple distinct members of the family in their genomes. In the most extreme case, the horn fly *Haematobia irritans* yielded evidence of seventeen distinct types of *Tc1* family elements. Most of the sequences obtained indicate that the elements are within the range of variation already known from fungi, nematodes, flies, fish, and frogs, however some had novel length variants or extremely divergent sequences, indicating that they represent new subfamilies of these transposons. These results indicate that this family of transposons is extremely common in animal genomes, with multiple representatives in most genomes.

09-049

VITELLINE MEMBRANE GENES IN *Aedes Aegypti* MOSQUITOES

M. J. Edwards and H. H. Hagedorn
Department of Entomology and Center for Insect Science,
University of Arizona, Tucson, AZ. U.S.A

A genomic clone corresponding to a novel *Aedes aegypti* vitelline membrane gene (15a-3) has been isolated. The predicted peptide sequence of 15a-3 is similar to those of the *A. aegypti* vitelline membrane genes 15a-1 and 15a-2. The deduced amino acid sequences of 15a-1, 15a-2 and 15a-3 contain a region of 45 residues which is highly conserved between the three genes. The conserved region overlaps with a region that is conserved between four *Drosophila melanogaster* vitelline membrane genes. DNA regions of approximately 1.8 kb, 2.1 kb and 2.0 kb were sequenced upstream of the 15a-1, 15a-2 and 15a-3 coding regions respectively. Sequences with similarity to a 20-hydroxyecdysone response element consensus sequence were found upstream of the 15a-1, 15a-2 and 15a-3 coding regions. The transcriptional regulation 15a-1, 15a-2 and 15a-3 was examined. The respective timing and sites of expression of the three transcripts were determined by Northern blot analysis and whole-mount *in situ* hybridization using mutually exclusive probes. The temporal pattern of 15a-1, 15a-2 and 15a-3 expression was similar. The spatial pattern of expression differed between the three genes. Only 15a-2 was expressed at the anterior region in addition to the remainder of the follicle. 15a-1 and 15a-3 were only expressed in the mid and posterior regions of the follicle. The effect of 10^{-5} M 20-hydroxyecdysone on vitelline membrane gene expression was examined *in vitro*. Expression of 15a-1 was higher in ovaries that were dissected at intervals of 0, 2, 10 and 24 h after a blood meal and were cultured in medium containing 20-hydroxyecdysone, as compared to control incubations. In ovaries that were dissected at 36 h after a blood meal, incubation in 20-hydroxyecdysone had no effect on 15a-1 expression, as compared to control incubations.

ORGANIZATION AND EVOLUTION OF AN AUTOSOMAL CHORION LOCUS IN THE MEDFLY *CERATITIS CAPITATA*

K. Vlachou and K. Komitopoulou

Department of Biology, Section of Biochemistry, Molecular and Cellular Biology and Genetics, Athens Greece

Four autosomal chorion genes, Ccs16, Ccs19, Ccs15 and Ccs18, and one non-chorion gene (NC-ORF), have been mapped on a chromosomal region of 20 kb, in *Ceratitis Capitata*. The chorion genes are tandemly arranged and individually regulated as shown by the temporally distinct expression of each one. The fifth gene is organized in the opposite orientation close to the 3' end of Ccs16. The two last exons of this gene have been sequenced and showed clear homology to myosin-like genes. Structural and regulatory evolution of the autosomal chorion loci in four distantly related *Drosophila* species and *Ceratitis capitata*, showed that this cluster is remarkably conserved in overall organization: all five species have preserved the same four chorion genes in the same order (s18, s15, s19 and s16) and with variation in spacing: in *Drosophila* species, the distance from the s18 transcriptional start site to the end of the s16 genes ranges from 5.5 to 7.0 kb while in *C. Capitata* it has expanded to 13.5 kb. The direction of transcription is also invariant both, within and across species: all genes are transcribed from the same strand and are identically oriented relative to NC-ORF which belongs to the same linkage group with chorion genes, in all studied species. Chorion genes are also highly conserved in developmental properties: in all five species they amplify extensively in the follicular epithelial cells, and produce exclusively follicular transcripts with gene specific temporal regulation, very similar in *Drosophila* species but slightly altered in *C. Capitata*. In contrast to this organizational and regulatory conservation, chorion gene DNA showed extensive sequence diversification, although not homogenous in distribution. The coding regions of the genes show a high degree of sequence divergence especially in *C. Capitata*, although in the proximal 5' flanking gene regions of homologous elements may have a very important role in regulation of transcription and amplification.

CLONING AND EXPRESSION OF AN INSECT GLUTAMATE TRANSPORTER GENE

B.C. Dooly, A. Richman¹, H.M. McLean¹, S. Caveney¹Pest Management Research Centre, Agriculture and Agri-Food Canada, London, Ontario, Canada - ¹ Department of Zoology, University of Western Ontario, London, Ontario, Canada

In recent years, great progress has been made in cloning and characterizing a number of molecular transporters responsible for the uptake of excitatory amino acids in mammalian systems. Strong homologies observed in the amino acid sequences of these proteins have suggested the occurrence of several large transporter families which are widely conserved. Making use of the mammalian sequences, we designed oligonucleotide primers to amplify homologous DNA fragments from insect cDNA by PCR. By this method, a DNA fragment was isolated from a cDNA library constructed from heads of the caterpillar *Trichoplusia ni*. The fragment produced was then used as a hybridization probe to isolate larger cDNAs.

The complete sequence of a 1.7 kilobase cDNA clone has been obtained, and found to contain an open reading frame encoding a protein with high homology to one transporter family described above. The deduced protein sequence is 44% and 45% identical to known rabbit and human glutamate transporters, respectively.

Expression of the isolated cDNA in a baculovirus expression system has been used to determine the characteristics of this insect transporter. Infected insect cells were found to exhibit greatly increased transport of various structural analogues of glutamate as compared to uninfected cells. This activity was completely Na⁺-dependent, suggesting the likelihood that the cloned transporter represents an insect homologue of this recently recognized family of mammalian glutamate transporters.

HORMONAL REGULATION OF VITELLOGENIN GENE EXPRESSION AND ITS STRUCTURE IN HOUSEFLY, *MUSCA DOMESTICA*N. Agui, T. Shimada¹, S. Izumi² and S. Tomino²Department of Medical Entomology, The National Institute of Health Shinagawa-ku, Tokyo, Japan -¹ Department of Agricultural Environmental Biology, The University of Tokyo, Bunkyo-ku Tokyo, Japan -² Department of Biology, Metropolitan University, Hachioji-shi Tokyo, Japan

Ecdysteroids induced vitellogenin synthesis and its gene activation in the ovaries of females and in fatbodies of both sexes in the housefly. Juvenile hormone (JH) acts only on female fly for induction of vitellogenin gene transcription (Agui *et al.*, 1985, 1991). Furthermore, our results showed that treatment of the female flies with JHA *in vivo* and *in vitro* increased ecdysteroid levels in hemolymph and ovary. This increase may contribute to the induction of vitellogenin gene expression. Thus, the role of JH in the vitellogenin gene expression is indirect and is mediated through stimulation of ecdysone synthesis in ovary. The ecdysteroid-receptor concentration in females was higher than that of males as measured by receptor-binding assays.

The female specific expression of the vitellogenin gene may depend upon the significant differences in ecdysteroid titer and ecdysteroid receptor levels between female and male flies. Furthermore, the presence of the reproductive organ, ovary itself, greatly contributes to the sex-specific expression of the vitellogenin gene by producing ecdysone.

We represent here that the sequences of the housefly vitellogenin gene (Mvg), which was isolated from a housefly genomic DNA library using the Mvg cDNA probe. The coding nucleotide sequence of Mvg showed high similarity with those in *Ceratitis capitata*, *Calliphora erythrocephala* and *Drosophila melanogaster*. The intron of Mvg has no homology, although its size and location is similar to that of *Drosophila*. The upstream sequences of the 5' end also showed no similarities with other YP genes within 200 base pairs upstream.

JUVENILE HORMONE INDUCES TRANSCRIPTION OF A TRYPSIN GENE IN *Aedes aegypti* MIDGUT

F.G. Noriega, D.K. Shah and M.A. Wells.

Department of Biochemistry and Center for Insect Science, University of Arizona, Tucson, USA.

Two types of trypsin are involved in blood meal digestion in the yellow fever mosquito, *Aedes aegypti*. Early trypsin is synthesized in small amounts within the first 4-6 hours following a blood meal. It is responsible for the first phase of tryptic digestion, which involves tasting of the meal and transcriptional activation of the more abundant late trypsin form. Early trypsin is an adult female-specific protein; transcription of the early trypsin gene begins shortly after emergence, and the mRNA level dramatically increases during the first day following emergence. In this poster we show that early trypsin gene expression is regulated by JH. Abdominal ligation within one hour after emergence silenced early trypsin gene expression. One hundred pg of topically applied methoprene (JH analog) restored early trypsin gene expression in ligated abdomens to values of non-ligated controls. The induction was dose dependent and "head-independent." In addition, methoprene was able to induce expression of the early trypsin gene in pupae.

GENE SEQUENCE AND ORGANISATION FOR A SEX LINKED ACETYLCHOLINESTERASE GENE IN INSECTICIDE RESISTANT *CULEX PIPPIENS*

C.A. Malcolm, A. Ascolillo, S.J. Rooker, L.M.C. Hall¹, D. Bourguet² and M. Raymond²

School of Biological Sciences, Queen Mary and Westfield College, University of London, UK

¹ Dept. of Medical Microbiology, London Hospital Medical College, University of London, UK

² Laboratoire Génétique et Environnement Université de Montpellier-II, France

Acetylcholinesterase (AChE) hydrolyses the neurotransmitter acetylcholine. The study of AChE in pest insects is important since it is the target for carbamate and organophosphate insecticides. Resistance has developed to these insecticides in several pest species involving an insensitive AChE.

A PCR generated homologous probe for part of a *Culex pipiens* AChE gene was used to screen a genomic DNA library prepared from a strain homozygous for insensitive AChE. Eight clones were isolated. Restriction enzyme mapping showed that these corresponded to three distinct maps containing a conserved region within which the probe hybridised. Two overlapping clones have been shown to match a sex linked gene by RFLP analysis (Bourguet unpub.). To date ~15 kb of these clones has been sequenced. The complex AChE gene organisation found in other Dipterans was present. Intron sizes were large: more comparable with the *D. melanogaster* AChE gene than other mosquito species. However the additional intron found in *A. stephensi*, but not other Dipteran AChE genes was present. The predicted amino acid sequence shows considerable homology to other mosquito AChE genes. No substitutions likely to confer insecticide insensitivity were discovered which is consistent with evidence that the factor determining insensitivity is autosomal (Bourguet unpub.).

SEQUENCE OF A CDNA CLONE ENCODING THE MOSQUITO L18 RIBOSOMAL PROTEIN

M.A. Hughes, T.F. Knapp, J.M. Crampton

Liverpool School of Tropical Medicine, Pembroke Place, Liverpool, L3 5QA, UK

An *Aedes aegypti* cDNA clone encoding the ribosomal protein-encoding gene, L18, has been isolated and the sequence determined. The cDNA clone was found to contain 672 bp, including a coding region of 560 nucleotides (nt) and a 3' extension of 112 nt. Comparisons between the coding regions of this clone to other known L18 aa sequences indicate good homology and their relationship is represented in the form of a phylogenetic tree. Evidence is presented to show that the *Ae. aegypti* sequence is a single-copy gene and that a comparable and closely related sequence exists in the mosquito, *Anopheles gambiae*. This is the first report of an insect L18 ribosomal protein-encoding gene.

THE HEAT SHOCK 70 GENES OF THE MEDFLY *Ceratitis capitata*: GENE ORGANIZATION AND STRUCTURE

E. Papadimitriou, D. Kritikou, M. Mavroidis, A. Zacharopoulou and A. Mintzas

University of Patras, Department of Biology, Division of Genetics, Cell and Developmental Biology, Patras, Greece.

The heat shock genes have been studied extensively in several organisms. The promoters of these genes are the best characterized highly induced DNA regulatory elements and they have been demonstrated to be important components of gene expression vectors. The cloning and characterization of the heat shock 70 (Hsp70) genes of the medfly *C. capitata* are presented in this work. Our goal is the development of medfly heat shock expression vectors which are anticipated to facilitate gene manipulation in this widespread and destructive insect pest.

Six genomic clones have been isolated by screening a medfly genomic library with an HSP70 genomic clone fragment of *D. melanogaster*. Restriction analysis indicated that the six clones are organized in two regions, approximately 30 kb each, and are mapped cytogenetically in one of the major heat shock puffs (3L:24C) of the salivary gland polytene chromosomes. Further analysis by a combination of restriction mapping and blot hybridization indicated the presence of six putative HSP70 genes in these two regions. One of these genes was further characterized by sequencing. Our data demonstrate that this gene is a heat shock inducible HSP70 gene: The coding region shows about 70% homology, at the nucleotide level, to the HSP70 genes of *D. melanogaster* and the 5' untranslated leader sequence (200 bp) is not interrupted by introns and is very rich (~48%) in adenine residues. Furthermore, the promoter of this gene contains two characteristic heat shock elements, 17 and 34 bp, upstream from the TATA box.

ANOPHELES GAMBIAE MIDGUT SPECIFIC GENES INDUCED BY A BLOOD MEAL: A DIFFERENTIAL DISPLAY ANALYSIS

G. Prévot, S. Bonnet, C. Bourgouin.

Ecologie des Systèmes Vectoriels, Institut Pasteur, 75015 Paris, France.

We are interested in identifying *Anopheles gambiae* genes involved in the penetration of *Plasmodium falciparum* ookinetes through the mosquito midgut. Characterization of such genes could permit the identification of targets or new means for blocking the development of the parasite in this host.
